*Membership.*—The Membership is open to University Graduates in Medicine and to Licentiates of the Royal Colleges of Physicians of the United Kingdom. The Examinations for Membership are held in January April, July, and October, and such other times as the President may appoint.

#### ROYAL COLLEGE OF SURGEONS, IRELAND.

This College grants a licence in Surgery to registered medical practitioners. Candidates who hold registrable surgical diplomas, including the licence of the Apothecaries' Society of London, and the Apothecaries' Hall, Dublin, granted since October, 1886, are admitted to examination without further evidence of study.

Candidates are examined in surgery, clinical and operative; surgical appliances; and ophthalmic surgery. The fee is £26 5s.

A diploma in Midwifery is also granted after examination to registered medical practitioners. Candidates must produce evidence of (a) attendance on a course of lectures on midwifery and diseases of women and children in a recognised school; (b) attendance or six months' practice at a recognised lying-in hospital or recognised dispensary for lying-in women and children; and (c) of having conducted at least thirty labour cases. The fee for the examination is £15 15s.

*Fellowship.*—Candidates for the Fellowship of the College must enter their names with the Registrar at least a month before the date of examination, in order that the Council may decide whether to approve of the application. Examinations are held the third Mondays in February, May, and November. If the application is approved, the candidate will be admitted to the next sessional examination or to a special examination (except during the months of August and September) if granted by the Council. Candidates are divided into two grades:—

Grade 1.—Licentiates or graduates in surgery of less than ten years' standing.

Grade 2.—Licentiates or graduates in surgery of more than ten years' standing. On and after January 1st, 1910, all examinations for the Fellowship will be conducted under the scheme now known as Grade 1. No candidate after the above date will, under any circumstances, be admitted to examination for the Fellowship of this College under the scheme now

known as Grade II., which will then cease to be used. Students, not either Licentiates or Graduates in Surgery, are permitted to present themselves for the Primary Examination under Grade I.

Candidates in Grade 1 must pass two examinations—Primary (in anatomy and physiology) and Final (in surgery). Candidates in Grade 2 need pass but one examination in surgery, surgical anatomy, and surgical pathology.

*Fees.*—Grade 1.—For Licentiates of College: Primary examination, £15 15s.; Final examination, £10 10s. Licentiates in Surgery of other licensing bodies: Primary examination, £26 5s.; Final examination, £15 15s. Students who have completed their second professional examination under the conjoint regulations: Primary examination, £5 5s.; Final examination, after obtaining the licence of the College, £21. Students of other licensing bodies: Primary examination, £10 10s.; Final examination, £31 10s.

Grade 2.—Licentiates of the College, £26 5s.; Licentiates in Surgery of other licensing bodies, £42.

*Licence in Dental Surgery.*—There is probably no specialty in surgery which gives as great a number of its practitioners a living and the prospect of an income as dentistry. A young man who has got his diploma and knows something of his business, and is willing to attend to it, seldom fails to get a substantial foothold in Ireland in a few years. The University of Dublin grants both a Degree and a Licence in dental surgery. To obtain the former, candidates must have taken a degree in arts; the licence is obtainable by all duly qualified persons who have passed the Public Entrance Examination of Trinity College, Dublin. The Royal College of Surgeons in Ireland grants a Licence in Dentistry.

*Course of Study for the Licence in Dentistry.*—Candidates are required to pass three examinations, viz.:—Preliminary (in General Education), Primary Dental, and Final Dental.

All information concerning this licence may be obtained from the Registrar of the College. The Primary Dental Examinations commence on the second Monday in the months of February, May, and November. The subjects of examinations include physics, chemistry (including metallurgy), anatomy, physiology and histology, and surgery. The fees for the primary Dental Examination amount to £10 10s.; and for re-examination, if rejected, £5 5s. The Final Dental Examinations commence on the Thursdays immediately following the Primary Dental Examinations. Candidates are examined in dental surgery, theoretical (including dental pathology), clinical, and operative; and in dental mechanics, theoretical, clinical, and practical (including the metallurgy of the workshop). Candidates must pass in all the subjects at the same time.

The fees for the Final Dental Examination in the case of candidates holding the L.R.C.S.I., or students who have passed the Primary Dental or Third Professional Examination of the College, £10 10s.; re-examination, £5 5s. The fees for Final Examination of all other candidates, £26 5s., and for re-examination, £10 10s. A rejected candidate will not be again admitted to examination until after a period of three months.

#### APOTHECARIES' HALL OF IRELAND.

The Licence of this Hall is granted to students who present certificates of having fully completed the course of study as laid down in the curriculum, and who pass the necessary examinations. The diploma of the Apothecaries' Hall of Ireland entitles the holder to be registered as a practitioner in medicine, surgery, and midwifery, and he also possesses the privileges of an apothecary.

There are four professional examinations, the total fees for which amount to 21 guineas. Women are eligible for the diploma.

Registered Medical Practitioners will receive the diploma of the Hall upon passing an examination in the subject or subjects not covered by their previous qualification, and on paying a fee of ten guineas; if

medicine or surgery is required, five guineas extra will be charged.

The fees payable for each examination are as follows : First Professional, £5 5s. ; Second, £5 5s. ; Third, £5 5s. ; Final Examination, £6 6s.

A candidate is allowed for each professional examination which he has completed at any other licensing body, except the Final. If he has passed only in some of the subjects in a given examination, he has to pay the whole of the fee for that examination.

The fees for re-examination are : For each subject, £1 1s., excepting in the subjects of surgery, medicine, and anatomy, the fees for which are £2 2s. each.

The fee for the Third and Final, or Final alone, is £15 15s., when the other examinations have been taken elsewhere.

All examination fees are to be lodged in the National Bank, College Green, Dublin, to the credit of the Examination Committee.

Applications and schedules, together with bank receipt for the fee, must be lodged with the Registrar, Apothecaries' Hall, 40 Mary Street, Dublin, at least fourteen clear days before the day of examination.

Candidates who desire to obtain the Letters Testimonial of the Apothecaries' Hall of Ireland, must, before proceeding to the Final Examination, produce evidence of having been registered as medical students for fifty-seven months ; also of having attended courses of instruction as follows :

One course each (winter course of six months) of the following : Anatomy (lectures), chemistry (theoretical), midwifery, practice of medicine, physiology and surgery. Dissections, two courses of six months each.

Courses of three months.—Materia medica, medical jurisprudence, chemistry (practical), practical physiology and histology, operative surgery, physics, clinical ophthalmology, biology, clinical instruction in mental disease, pathology, and a course in vaccination.

Medico-Chirurgical Hospital, twenty-seven months to be distributed over the last four years of study. The candidate may substitute for nine months in this, hospital attendance six months as a resident pupil.

Three months' study of fever.

Six months' practical midwifery and diseases of women.

Three months' practical pharmacy in a recognised clinical hospital or a recognised school of pharmacy, or a year in the compounding department of a licentiate apothecary or a pharmaceutical chemist.

Each candidate before receiving his diploma must produce evidence that he has attained the age of 21.

Each candidate must produce evidence of having before entering on medical studies passed a preliminary examination in general education recognised by the General Medical Council, and of having been registered by that Council as a student in medicine. Certificates of medical study will not be recognised if the commencement of the course to which the certificate refers dates more than fifteen days prior to such registration, except in the subjects of physics and biology. This registration is not undertaken by the Hall.

The details of the course of education required and syllabus of the examinations will be supplied on application to the Registrar, at 40 Mary Street, Dublin.

#### THE DIPLOMA IN PUBLIC HEALTH.

This diploma is granted by Dublin University, the Royal University, and the Conjoint Royal Colleges. Every candidate must be a registered medical practitioner. The examination is in :—(1) Chemistry (including chemical physics). (2) Engineering and architecture. (3) Sanitary law and vital statistics. (4) Hygiene. (5) Bacteriology. (6) Meteorology. The General Medical Council recommend that all candidates shall have studied in a special bacteriological laboratory, also for six months as pupil of a working medical officer of health, described, for Ireland, as "the medical officer of health of a county or of one or more sanitary districts having a population of not less than 30,000 ; or a medical officer of health who is a teacher in Public Health of a recognised medical school."

In addition to taking the prescribed course a candi-

date for the D.P.H. of the University of Dublin must be a Doctor in Medicine or a graduate in Medicine, Surgery, and Midwifery of Dublin, Oxford, or Cambridge, or a Doctor in Medicine of London, and his name must have been on the "Medical Register" for at least twelve months before the examination. The Royal University only confers its diploma on its own graduates.

#### THE DIPLOMA IN PSYCHOLOGICAL MEDICINE.

The Royal University of Ireland grants a diploma for proficiency in the treatment of mental diseases under the following conditions :—

The diploma is conferred only on graduates in medicine of the University. Candidates must give notice, in writing, to the secretaries of their intention to present themselves, and must pay the prescribed fee of £2 at least one month previous to the examination. Candidates who satisfy the examiners will be required to pay a further fee of £3 before the diploma is conferred. The subjects for this examination are those required by the Hutchinson Stewart Scholarship for proficiency in the treatment of mental diseases.

#### THE IRISH MEDICAL SCHOOLS.

The Irish Medical Schools are as follows :—

**THE SCHOOL OF PHYSIC OF DUBLIN UNIVERSITY.**—This school is formed by an amalgamation of the School of Trinity College and of the College of Physicians.

Every student of the school must be matriculated in Medicine, for which a fee of 5s. is payable, but he need not attend any of the Arts course unless he desires to obtain a University licence or degree in medicine, surgery, and midwifery. No student is permitted to matriculate unless he has passed the Entrance examination of the University, or some other examination recognised by the General Medical Council. Two medical scholarships are given annually at the School of Physic, value £20 per annum, tenable for two years, the examinations for which are held each year in June ; one scholarship is given in anatomy and institutes of medicine ; the other in zoology, chemistry, botany, and experimental physics. A prize of £100 is awarded by the Board to the successful candidate at a special examination in alternate years in medicine or in surgery, provided that the merit be deemed sufficient. The successful candidate is required to spend three months in the study of medicine or surgery, as the case may be, in Berlin, Paris, or Vienna. Before he can obtain the first instalment of £50 he must satisfy the Senior Lecturer that he possesses sufficient knowledge of a Continental language to derive full benefit from the prize. The examination is held in June, and is open to students who have passed the Final Examination in Medicine or in Surgery, as the case may be, within two years of the examination.

In order to obtain the second sum of £50 the prizeman must have furnished to the Regius Professor his formal report on the hospitals attended by him within two years from the time of obtaining the prize.

The Sir John Banks Medal and Prize, founded by the late Sir J. Banks, M.D., Regius Professor of Physics, are awarded to the best and second best answerers at the Medical Travelling Prize Examination.

The Edward Hallaran Bennett Medal and Prize, founded by pupils of the late Dr. E. H. Bennett, formerly Professor of Surgery, are awarded to the best and second best answerers at the Surgical Travelling Prize Examination. Class prizes are given at the end of the session of between £5 and £10 in value. The John Mallet Purser Medal, founded by Prof. Purser's past pupils, is awarded annually to the student who, at the ordinary June Intermediate Medical Examination, Part I., in Anatomy and Institutes of Medicine, shall obtain highest marks in Physiology and Histology, provided that he passes the examination in full.

**Fitz-Patrick Scholarship.**—This scholarship consists of the interest on £1,000. It will be awarded annually to the student who obtains the highest aggregate marks at the five sections of the Final Examinations, provided that he has completed his medical course in the prescribed period of five years.

**THE ROYAL COLLEGE OF SURGEONS IN IRELAND, SCHOOLS OF SURGERY.**—These schools are attached by Charter to the Royal College of Surgeons, and have existed as a department of the College for over a century. They are carried on within the College buildings, and are specially subject to the supervision and control of the Council, who are empowered to appoint and remove the professors, and to regulate the methods of teaching pursued. The buildings have been reconstructed, the capacity of the dissecting room nearly trebled, and special pathological, bacteriological, public health, chemical, and pharmaceutical laboratories fitted with the most approved appliances, in order that students may have the advantage of the most modern methods of instruction. There are special rooms set apart for lady students. The entire building is heated by hot-water pipes, and lighted throughout by the electric light.

All the lectures and courses of practical instruction may be attended by medical students who are otherwise unconnected with the College.

All the diplomas of the College are open to students of either sex. Separate rooms have been provided, and careful provision made for the instruction and comfort of women students.

**Prizes.**—The Barker Prize, £31 10s.; the Carmichael Scholarship, £15; the Mayne Scholarship, £8. The Gold and Silver Medals in Surgery and the Stoney Memorial Gold Medal in Anatomy.

Class Prizes of £2 and £1, accompanied by medals if sufficient merit is shown, will also be given in each subject. Prospectus and Student's Guide can be obtained on written application to the Registrar, Royal College of Surgeons, Dublin.

**THE CATHOLIC UNIVERSITY SCHOOL** is situated in Cecilia Street, Dublin. It prepares students for all medical examinations, particularly those of the Irish Colleges of Physicians and Surgeons, and the Royal University of Ireland. The school has recently been rebuilt and refitted, its working space having thereby been nearly doubled, and several new laboratories, including those for the study of bacteriology and public health, have been added. The institution has also been recently chartered, under the Educational Endowment (Ireland) Act, and it is now controlled by a Board of Governors. The total fees for school and hospital courses is £124 19s., payable as the courses are taken out.

The following Exhibitions are awarded annually:—Two first year's, value £12 10s. each; two second year's, value £10 each; one third year's Royal Exhibition of £12 10s.; one final Conjoint Colleges Exhibition of £12 10s.; two large gold medals, besides several other class medals. Molloy Prizes in Chemistry and Physics, Ambrose Birmingham Memorial Prize in Anatomy.

A Guide for Medical Students, which gives all the information required by parents, and by students who desire to join the medical profession, may be obtained free on application to the Registrar.

This school is likely to be merged in the medical school of University College, Dublin.

#### THE UNIVERSITY COLLEGES—CORK AND GALWAY.

These important academic institutions educate students for all colleges and degrees, and are maintained, as hitherto, by a Government grant. The same curriculum as that formerly adopted is continued, and the various exhibitions and scholarships are still available. Each college has the disposal of about £1,500 per annum in scholarships and prizes. The colleges are well adapted for high-class technical education, having lecture rooms provided with every appliance necessary in the modern training of a medical student. The colleges are completely equipped with students' reading rooms and lending libraries and refreshment rooms, and with all adjuncts to collegiate life, such as literary societies and athletic organisations. The expense of living in the collegiate towns is quite moderate. The course of lectures in the winter session must be diligently attended, no student obtaining a

certificate who has not put in three-fourths of a course. The scholarship examinations are held in October.

These Colleges are now constituent colleges of the National University of Ireland, and conduct examinations admitting to its degrees.

#### THE QUEEN'S UNIVERSITY OF BELFAST.

This University provides all the classes required for a complete medical curriculum. The University contains laboratories in connection with the departments of Biology, Chemistry, Physiology, Pathology, Anatomy, Physics, and Materia Medica. In connection, too, is a Students' Union, which gives students the advantage of dining-rooms, reading-rooms, a library, and various recreation rooms. Women are eligible as students. Clinical instruction is given at the Royal Victoria Hospital, which was rebuilt a few years ago, and has 300 beds, and at the Mater Infirmorum Hospital, which has 150 beds. Other hospitals open to the students of the University are: The Maternity Hospital, the Ulster Hospital for Women and Children, the Hospital for Sick Children, the Ophthalmic Hospital, the Benn Ulster Eye, Ear, and Throat Hospital, the Union Infirmary and Fever Hospital, the Fever Hospital, Purdysburn, and the District Lunatic Asylum.

**Scholarships.**—(1) Ten medical scholarships value £20 each; (2) two Dunville Studentships (one each alternate year), value £150 each; (3) one Andrews Studentship each alternate year, value £145; (4) numerous sessional prizes.

Additional scholarships will be open for competition at the medical examinations in March and June, 1910. There is also a Post-Graduate Research Fund open to all graduates of not more than three years' standing. Information regarding these scholarships, etc., may be obtained on application to the Dean of the Faculty of Medicine.

**Fees.**—The cost of the curriculum intended for students proceeding to the degrees of the Queen's University of Belfast is, approximately, £104. This includes examination fees and a perpetual ticket for attendance at the Royal Victoria Hospital or the Mater Infirmorum Hospital, but not fees for the special hospitals. The course for the Conjoint Board costs about the same amount.

A pamphlet containing full information regarding the new regulations for courses, fees, etc., can be had free of cost on application to the Registrar, Queen's University, Belfast.

#### UNIVERSITY COLLEGE, CORK.

The arrangements in the Faculty of Medicine are made chiefly with reference to the requirements of the Royal University of Ireland, but students proceeding for the examinations of the Conjoint Boards of England, Scotland, or Ireland, the Society of Apothecaries of London, or the Apothecaries' Hall of Ireland, can arrange the course of lectures which they attend, and the order in which they attend them, to meet the requirements of those bodies. Certificates of attendance in the college are also accepted by the University of Cambridge. The total fees for the college lectures and Hospital attendances required by the Royal University of Ireland is about £85.

The College is a Constituent College of the National University of Ireland, and will in future conduct the examinations for the Medical Degree of that University.

Clinical instruction is given at the North and South Infirmarys. Students can also attend the Mercy Hospital, the Cork Union Hospital, the County and City of Cork Lying-in Hospital, the Maternity, the Hospital for Diseases of Women and Children, the Fever Hospital, the Ophthalmic and Aural Hospital, and the Eglinton Lunatic Asylum. The winter session commences on October 20th, and ends at the end of April. The courses of the summer session are delivered in the months of April, May, and June.

**Scholarships and Prizes.**—Eight medical scholarships, two in each of the first four years, of the value of £25 each, and in the fifth year the Blaney Scholarship of the value of about £32, and a Senior Exhibition, value £30. Three Exhibitions, one in practical medicine, one in

practical surgery, and one in practical midwifery, each of the value of £15. Book prizes at the sessional examinations.

Further information can be obtained in the College Regulations, or on application to the Registrar, Queen's College, Cork.

#### UNIVERSITY COLLEGE, GALWAY.

Clinical teaching is carried on in the Galway Hospital, established as a Public General Hospital (in the place of the County Galway Infirmary) by Act of Parliament (1892). The Galway Fever Hospital and Galway Throat Hospital are also open to students. The medical lectures are recognised by the Royal University of Ireland and the various Licensing Bodies in the United Kingdom.

**Prizes.**—There are eight Junior Scholarships in Medicine of the annual value of £25 each. Two are tenable by matriculated students of the first, second, third, and fourth years. The Council has power to award exhibitions for distinguished answering. Sessional prizes are offered in each subject.

Like the sister College of Cork, this college is now a constituent college of the National University of Ireland.

#### ROYAL COLLEGE OF SCIENCE FOR IRELAND.

SESSION 1909—1910.

This College, situate in St. Stephen's Green, Dublin, supplies a complete course of instruction in science applicable to the industrial arts, especially those which may be cast broadly under the heads of Agriculture, Chemical Manufactures, Engineering, Physics, and Natural Science. A Diploma of Associate of the College is granted at the end of the three years' course. Non-Associate students may join for any course required. There are several entrance scholarships, (a) in Agriculture, and (b) in Science and Technology, tenable for three years, of the value of £50 each yearly, with free tuition. There are four Royal scholarships of the value of £50 each yearly, with free education, tenable for two years. Two are competed for by the first year associate students at the end of each session. All the laboratories and drawing schools are open daily for practical instruction. The Session commences on Tuesday, September 28, 1909. The Science Scholarship Examinations are held during the first week in July, the Examinations for Agricultural Scholarships in the first week in September, and the Entrance Examination for intending Associates in the third week of September, 1910. For further particulars and copy of college programme apply to the Registrar.

#### THE DUBLIN HOSPITALS.

THE clinical hospitals in Dublin are ten in number, exclusive of three lying-in hospitals. There are also two children's hospitals, an orthopaedic hospital, a fever hospital, an ophthalmic hospital, a dental hospital, and other special institutions. Some of the clinical hospitals, though they have no actual or official connection with any school, are in close affinity with certain teaching bodies; while others, again, are without any special connection with any school. While, however, such affiliation of a school or hospital may exist, it should be remembered that the Dublin schools and hospitals are open to all comers, and the student is competent to attend any hospital or any school he wishes, and to change his place of instruction from year to year as he may see fit.

The Irish Licensing Bodies require attendance on hospitals for twenty-seven months, i.e., three winter sessions of six months and three summers of three months, within the five years of study. The fee at all general hospitals is £8 8s. in winter, and for the summer £5 5s., or £12 12s. for the entire session of nine months if taken together.

#### GENERAL HOSPITALS.

**RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.**—These hospitals contain over 300 beds. They are visited each morning at nine o'clock by the physicians and surgeons, and, in addition to the usual bedside instruction, clinical lectures

are delivered on the most important cases. Instruction is also given on various special branches of medicine and surgery. The Truss Establishment, for the distribution of trusses to the ruptured poor of Ireland, is connected with these hospitals. There are large ophthalmic, aural, throat, and gynaecological dispensaries, and instruction in these important subjects is given. A fully equipped, modern, pathological laboratory, and a new mortuary have been opened recently. Twelve resident clinical clerks are appointed each quarter, and provided with furnished apartments, fuel, &c. The appointments are open not only to advanced students, but also to those who are qualified in medicine and surgery. A house surgeon for the Richmond Hospital and a house physician for the Whitworth and Hardwicke Hospitals are elected every six months, and receive a salary. The Richmond Lunatic Asylum, containing 1,200 beds, adjoins these hospitals.

**MEATH HOSPITAL AND CO. DUBLIN INFIRMARY.**—This hospital was founded in 1753, and now contains 160 beds available for clinical teaching. A new building for the isolated treatment of fevers, containing 40 beds, has recently been added. The certificates of this hospital are recognised by all the Universities and licensing bodies of the United Kingdom. Medical and surgical resident pupils and clinical clerks and dressers are appointed every three months, and a house surgeon is elected annually. A prospectus giving the complete arrangements for medical and surgical classes for the coming session may be obtained from the Secretary of the Medical Board, Mr. William Taylor, F.R.C.S., 47 Fitzwilliam Square.

**THE ADELAIDE MEDICAL AND SURGICAL HOSPITALS.** occupy a central position within a few minutes' walk of the College of Surgeons and Trinity College. From October 1st, the physicians and surgeons visit the wards and give instruction at the bedside at the advertised hours. There is a large detached fever hospital, and there are also wards for infants and children. Operations are performed, at 10 a.m. on Tuesday, Thursday, and Saturday. Special hours are devoted to clinical instruction in the diseases peculiar to women, and students are individually instructed in the use of the stethoscope, ophthalmoscope, laryngoscope, and microscope; also special instruction is given on practical pathology and X-ray photography. Two House Surgeons are elected annually and four resident pupils half-yearly. Prize examinations, including examinations for the Hudson Scholarship, £30 and a gold medal, and Hudson prize of £10 and a silver medal, in addition to surgical, medical and dermatological prizes, are held at the termination of the session. The large dispensaries afford facilities for the study of eye, ear, throat, and cutaneous diseases, as well as of minor surgery and dentistry. Further particulars from Mr. Heuston, F.R.C.S.I., 15 St. Stephen's Green North.

**THE ROYAL CITY OF DUBLIN HOSPITAL.**—This hospital has recently been enlarged and improved to a very considerable extent. A special course of instruction is given on ophthalmic and aural diseases. There are special wards for the treatment of diseases of the eye, of children, and of women, and practical instruction is given on diseases peculiar to women; there is also a separate building for infectious diseases. Clinical clerks to the physicians and dressers to the surgeons are appointed from the most deserving of the class. A new operation theatre, sterilising room, and anaesthetic room have been constructed in accordance with the most modern surgical requirements. A department for Röntgen-ray and light treatment of lupus has recently been added. A resident medical officer is elected annually, and resident medical and surgical pupils are appointed from among the past and present students of the hospital. Operations are performed on Tuesdays, Thursdays, and Saturdays, at 10 a.m. Special classes for first year students. Full particulars can be had on application to Hon. Sec. Med. Board.

**SIR PATRICK DUN'S HOSPITAL** is situated on the south-eastern side of the city, and about a quarter of a mile

from the University School of Physic. It is officered almost exclusively by the professors and examiners in that school. Formerly all University students were compelled to attend this hospital, which was purely a medical institution, but many years ago the obligation was removed, and the hospital was opened for surgical cases. It is now open to all students. There is a special wing devoted to fever cases, and regular clinical instruction is given by the members of the medical staff throughout the winter and summer sessions. Special classes for students commencing their hospital studies will be held in the wards during the months of October, November, and December. They will embrace the elements of medicine and surgery, including note-taking. Opportunities are also afforded to students for examining cases of throat, ear, and eye diseases, as well as for performing minor surgical operations and bandaging. In the X-ray Department opportunities are given the members of the hospital class of seeing the various applications of the X-rays to the diagnosis and treatment of injury and disease. Arrangements have been made for practical instruction in anæsthetics.

**MATER MISERICORDIÆ HOSPITAL, Dublin.**—Consulting Physician: Sir Francis R. Cruise. Physicians: Sir Christopher Nixon, Bart., Dr. Joseph Redmond, Dr. John Murphy, and Dr. Martin Dempsey. Surgeons: Sir Arthur Chance, Mr. John Lentaigne, and Mr. Alexander Blaney. Assistant Physician: Dr. John O'Donnell. Assistant Surgeon: Mr. Farnan. Obstetric Physician: Dr. Robert Farnan. Ophthalmic Surgeon: Mr. Louis Werner. Surgeon for Diseases of Throat and Nose: Mr. Patrick Dempsey. Dental Surgeon: Mr. E. Sheridan. Pathologist: Dr. Edmond McWeeney. Assistant Pathologist: Mr. W. D. O'Kelly. Anæsthetist and Surgical Registrar: Dr. Patrick O'Farrell. This hospital, the largest in Dublin, at present containing 345 beds, is open at all hours for the reception of accidents and urgent cases. Clinical instruction will be given by the Physicians and Surgeons at 9 a.m. daily. A course of Clinical Instruction on Fever will be given during the winter and summer sessions. A certificate of attendance upon this course, to meet the requirements of the licensing bodies, may be obtained. Opportunities are afforded for the study of Diseases of Women in the ward under the care of the Obstetric Physician, and at the Dispensary held on Tuesdays and Saturdays. Ophthalmic Surgery will be taught in the Special Wards and in the Dispensary. Surgical Operations will be performed on Mondays, Tuesdays, Fridays and Saturdays at 11 o'clock. Connected with the hospital are extensive Dispensaries, which afford valuable opportunities for the study of general Medical and Surgical Diseases, and Accidents. Instruction will be given on Pathology and Bacteriology. Two House Physicians, six House Surgeons, and 16 resident pupils will be elected annually. Dressers and Clinical Clerks will also be appointed, and certificates will be given to those who perform their duties to the satisfaction of the staff. Leonard Prizes will be offered for competition annually. For further particulars see prospectus. Certificates of attendance upon this hospital are recognised by all the Universities and licensing bodies in the United Kingdom. Private Wards have been opened for the reception of Medical and Surgical cases. A Training School and a Home for Trained Nurses have been opened in connexion with the Hospital.

*Terms of attendance.*—Nine months, £12 12s.; six winter months, £8 8s.; three summer months, £5 5s. Entries can be made with any of the physicians or surgeons, or with the Registrar, Dr. Martin Dempsey, 35 Merrion Square. A prospectus containing in detail the arrangements for Clinical Instruction, Prizes, etc., may be obtained from the Secretary, Medical Board.

**MERCER'S HOSPITAL.**—This hospital, founded in 1734, is situated in the centre of Dublin, in the immediate vicinity of the Schools of Surgery of the Royal College of Surgeons, the Catholic University School of Medicine, and Trinity College. It contains 120 beds for medical and surgical cases, and arrange-

ments have been made with the medical officers of Cork Street Fever Hospital whereby all students of this hospital are entitled to attend the clinical instruction of that institution and become eligible for the posts of resident pupil, &c. There is a large out-patient department, and a special department for diseases peculiar to women. There are also special wards for the treatment and study of children's diseases. During the past few years the hospital has undergone extensive alterations in order to bring it up to modern requirements. A house surgeon is appointed annually. Five resident pupils are appointed, each for six months, and clinical clerks and dressers are appointed monthly from among the most deserving members of the class. The certificates of this hospital are recognised by all the licensing bodies. For further particulars apply to Mr. Seton Pringle, F.R.C.S., 27 Lower Baggot Street, Dublin.

**ST. VINCENT'S HOSPITAL** was established in 1834, it has 160 beds, and in connection with it there is a largely-attended dispensary, a convalescent home, and a nurses' institute. In addition to the ordinary clinical instruction, systematic courses of lectures are given in each department of medicine and surgery, and are illustrated by cases in the hospitals. The resident officers consist of two house surgeons, two house physicians, and six resident pupils. Three clinical lectures are delivered daily in the wards, illustrated by selected cases, and beginning at 9 a.m. Two gold medals and other valuable prizes and certificates of merit are awarded at the end of each session. A prospectus can be had from Mr. Fagan, 31 North Frederick Street.

**DR. STEEVENS' HOSPITAL**, situated at Kingsbridge, is the oldest and one of the largest clinical hospitals in Dublin, and contains over 200 beds. A very fine Nurses' Home was recently added to the institution, with accommodation for over seventy nurses. A new and thoroughly equipped dispensary and out-patient department has been completed and opened to patients. There is accommodation for twelve resident pupils—four medical, six surgical, and two in the special departments, each of whom is supplied with a separate room. All information with regard to these appointments can be had from the Resident Medical Officer at the hospital. Licensing bodies recognise six months' residence as equivalent to a year's ordinary attendance at hospital. The manufactories and railway works in the neighbourhood supply this hospital with large numbers of accidents and other cases, while a special ward for venereal diseases affords exceptional opportunities for the study of this important subject.

**JERVIS STREET HOSPITAL** is one of the oldest established in Dublin. The new hospital was completed in 1896, since which time it has been open for the reception of patients. In addition to large medical and surgical dispensaries, the out-patient department includes special departments for the treatment of diseases of the skin, eye, ear, and throat, and diseases peculiar to women. Two resident surgeons are appointed annually. Clinical clerks and surgeons' dressers are selected from among the most attentive of the advanced students without the payment of any additional fee. Twelve interns are appointed annually, and are provided with apartments, &c., free of expense. Special certificates are given to resident pupils and dressers who have performed their respective duties to the satisfaction of the physicians and surgeons.

Students of Jervis Street Hospital are entitled to attend free of charge the Children's Hospital, Temple Street, which contains 100 beds, where special lectures are given on Diseases of Infancy and Childhood, and on Orthopædic Surgery and appliances, and to obtain special courses in fevers at Cork Street Fever Hospital.

**X-Ray and Finsen Light Department.**—Demonstrations in this important branch will be given three times weekly by Dr. Henry Mason and the Students of the Hospital.

## SPECIAL HOSPITALS.

The special hospitals of Dublin are the Rotunda, the Coombe, and the National Lying-in-Hospitals, Cork Street Fever Hospital, the Royal Victoria Eye and Ear Hospital (amalgamation of St. Mark's Ophthalmic Hospital and the National Eye and Ear Hospital), the Dental Hospital, the Orthopædic Hospital, and the Children's Hospitals in Harcourt Street and in Temple Street.

**THE ROTUNDA HOSPITAL.**—This institution is the largest, the longest established gynæcological as well as maternity hospital in the British Empire. The work performed by it is about three times greater than that of any other hospital of its kind in Ireland. The number of patients admitted to the hospital, and also attended in the extern maternity has increased enormously within recent years. The routine daily work comprises the attendance of lectures on midwifery and gynæcology; practice in abdominal palpation; personal conduction of parturition both in the extern and the intern maternities; cystoscopic examinations, as well as attendance at the operation work of the hospital. The hospital affords exceptional advantages to qualified men who take out a three months' course during the autumn, winter, and spring months, for they (if considered competent) are permitted a certain amount of practical operation work, viz.—forceps, curettings, perineorrhaphy, &c. A special afternoon class in gynæcology is held by the Senior Assistant, and one in special pathology by the Pathologist. Fee for each, £2 2s. per month. The Pathological laboratory under the direction of Dr. Rowlette has become an important feature of the hospital. Students can enter at any time for periods of one month or longer. Certificates of attendance are accepted by all the licensing bodies. The L.M. certificate is obtained by attendance at the hospital for six months, with the subsequent passing of an examination. A special certificate in gynæcology is presented to students whose work meets with the Master's approval. Paid clinical assistants are selected (from amongst those who have obtained the hospital L.M. certificate), for periods of six months. The residents' quarters have undergone complete renovation and now afford comfortable accommodation. Women students can also reside in the house under conditions similar to men. The grounds of the hospital contain asphalt and grass courts for lawn tennis and croquet. There is also a full-size billiard table.

**Fees for Pupils.**—Intern 1.—One month, £6 6s.; two months, £9 9s.; three months, £12 12s.; six months, £21; single months other than the first, £4 4s.; board and lodging in the house per week, £1 5s. Night students (not resident in house), £6 6s. for first three months; £4 4s. for the second three months. For further particulars apply to Dr. E. Hastings Tweedy, Master, Rotunda Hospital, Dublin.

**COOMBE LYING-IN HOSPITAL.**—This hospital, which devotes itself to the care of lying-in women, and to the treatment of diseases peculiar to women, was founded in 1826. The original hospital was removed, and the present maternity hospital erected in 1875. An up-to-date labour theatre and waiting ward were added in 1904. The new Gynæcological Hospital was finished in 1903. It contains two modern operating theatres. The former Gynæcological Hospital has been converted into sleeping rooms for resident pupils. The hospital is situated centrally in a most densely populated district. In addition to a very large gynæcological practice, over 2,000 women are delivered annually. The Master visits the maternity wards daily with the students at 9.30 a.m. This is followed by a lecture on midwifery. At 11 a.m. the gynæcological wards are visited; following this a lecture on gynæcology, physical examinations, and operations take place in the theatres. At 4 p.m. on Mondays, Wednesdays, and Fridays, the Master conducts the gynæcological out-patient dispensary. This dispensary affords students exceptional advantages of acquiring a thorough knowledge of gynæcologi-

cal diagnosis. At 5 p.m. on Tuesdays and Thursdays, the Master conducts a special class in practical obstetrics, including palpation, auscultation, pelvimetry, and operations on the phantom. Lady medical students can reside in the hospital. Extern assistants are appointed from among the students as vacancies occur. These most responsible appointments afford the students every opportunity of making themselves competent in practical midwifery. Candidates for the diploma of the Coombe Hospital shall have their names on the books of the hospital for six months, during which time they shall attend as frequently as possible, and be present at 30 deliveries. They shall then present themselves for examination, and if found qualified will receive the diploma. The catering for the residents is in the hands of a competent house-keeper. Board and lodgings, £1 per week. The students' quarters are comfortably furnished.

**Fees.**—Extern pupils (for full course of six months), £8 8s. This includes one month's residence in hospital. Intern pupils—one month, £4 4s.; each consecutive month, £3 3s.; six months and L.M. diploma, £18 18s. Board and lodging in the hospital, 18s. per week. Lady students, intern—one month, £5 5s.; each consecutive month, £4 4s.; six months and L.M. diploma, £18 18s. Registration fee, 10s. 6d. There is no extra charge for attendance at any of the dispensaries. Certificates of attendance from this hospital are accepted by all the licensing bodies.

**\* NATIONAL MATERNITY HOSPITAL.**—This institution, under the mastership of Dr. A. Horne, is situated in Holles Street.

**CORK STREET FEVER HOSPITAL,** 266 beds, is the only special fever hospital in Dublin. It is supported mainly by subscriptions, an annual Government grant, and capitation grants for patients. Regular clinical instruction is given during the winter and summer sessions to those who desire a special course in fevers. There are also courses for the Diploma in Public Health. All particulars may be obtained on application to the Medical Superintendent.

**THE NATIONAL CHILDREN'S HOSPITAL** for the treatment of all non-infectious diseases peculiar to children, with which the Pitt Street Children's Hospital, founded in 1821, was amalgamated, contains 42 beds for the reception of cases of deformity and all other forms of surgical disease. There is a large general dispensary for extern patients held daily from 10 to 11. Operations are performed on Saturday at 12 o'clock. Practitioners and students can attend on application to Sir Lambert H. Ormsby, F.R.C.S.I.

**\* THE CHILDREN'S HOSPITAL,** Temple Street, Dublin (under the care of the Sisters of Charity).—This institution is the largest children's hospital in Ireland. There are 100 beds available for patients; about 1,000 cases are admitted to the wards annually; and about 7,000 or 8,000 seen in the dispensary. During the last year a new operating theatre has been opened. It is fitted and furnished in the best possible fashion for present-day surgery. Special attention is given to orthopædic surgery, and the number of deformities from all parts of Ireland treated and cured in the hospital is rapidly increasing. A special masseuse has been appointed to the hospital to aid in this department.

The hospital is recognised for clinical instruction in the diseases of children by the R.U.I. and licensing bodies, which require a certificate of instruction in this important branch of medical education. A nursing home is in connection with the institution, and trained nurses are always available for private cases. Senior students or others requiring a post-graduate course at the hospital should apply for full particulars to Dr. M. C. Staunton, hon. sec., or to any member of the staff.

**THE INCORPORATED ORTHOPÆDIC HOSPITAL, IRELAND.**—This hospital was founded in 1876, and contains 80 beds. It is available for every class of deformity available for treatment. Particulars may be obtained from Captain Borthistle, secretary, at the hospital.

**THE ROYAL VICTORIA EYE AND EAR HOSPITAL,** Adelaide Road.—This hospital, which was opened

in March, 1904, is an amalgamation of St. Mark's Ophthalmic Hospital and the National Eye and Ear Infirmary. The hospital contains 80 beds. Clinical instruction in diseases of the eye and ear, including the use of the ophthalmoscope and operations, is given daily from 10 till 1. Special classes for practical instruction in the use of ophthalmoscope, &c., and for the demonstration of cases, are formed from time to time.

**THE INCORPORATED DENTAL HOSPITAL**, Lincoln Place.—This hospital, recently erected, is the only special Dental Hospital in Dublin. It is officered by a very strong staff of the leading dental surgeons of Dublin, and has a large *clientèle* and extensive practice among the Dublin poor. The fees are £15 15s. for the first year's study, and £15 15s. for second, and proportionately smaller fees for shorter periods.

#### BELFAST HOSPITALS.

**HOSPITAL FOR SICK CHILDREN**, Queen Street.—This institution, erected by voluntary donations, and supported by voluntary contributions, was opened for the reception of patients on April 24th, 1879. The hospital consists of a medical ward with twenty-eight beds, and one of a similar size for surgical cases. It is strictly non-sectarian in its principles, and is open to all denominations. Children from birth to the age of 12 years, and not suffering from contagious disease, are admissible as in-patients. A very large extern is conducted in the out-patient department between the hours of 9 and 10 a.m., where children from birth to 14 years are attended to. During the winter session systematic courses of lectures and demonstrations in the medical and surgical diseases of infancy and childhood are delivered in the wards on Wednesday and Saturday of each week at 9 a.m. At the close of the session an examination is held, and a gold medal awarded if sufficient merit has been shown.

\***MATER INFIRMORUM HOSPITAL**.—Established 1883. 160 beds. The New Mater Hospital, which was erected at a cost of over £50,000, was formally opened on April 23rd, 1900. During the year the intern patients numbered 1,525; accidents, 3,762, and cases treated in the Dispensary, 22,597; 389 surgical operations were performed with the most satisfactory results. The total number of patients who received treatment was 27,884, being an increase of 1,517 as compared with the year 1904. A notable feature is in the number of accident cases, as the hospital is conveniently situated in proximity to a large working-class population, and within easy reach of most of the public works.

**THE BELFAST MATERNITY HOSPITAL (INCORPORATED)**.—Established 1794. 30 beds.—The practice of the Maternity Hospital, the certificate of which is recognised by all the Universities and Colleges, &c., &c., is open to students. The fee for the session is £2 2s. Resident nurses are also received for training for a period of six months, and a diploma given which is recognised by public bodies. The hospital course is also recognised by the Central Midwives Board. Conditions for such on application to the Matron. During the year 1908, 488 patients were treated in the hospital, and 416 patients at their own homes. Besides this, 185 patients were dealt with in the extern gynaecological department. Clinical lectures and bedside demonstrations are given by members of the staff during both the winter and summer sessions. Students wishing to attend should apply to Dr. H. D. Osborne, 32 Lonsdale Terrace, Belfast, Hon. Secretary to Medical Staff, on or before November 1st and May 1st.

*Note.*—Hospital was rebuilt in 1904 and removed to splendidly equipped new premises in Townsend Street. A Resident Surgeon elected periodically.

**OPHTHALMIC INSTITUTION AND EYE AND EAR HOSPITAL**, Great Victoria Street, Belfast.—Established 1844. New hospital erected, 1867. Operation theatre added, 1902. New extern department, 1909. This hospital is situated on the main road between Queen's College and the Royal Victoria Hospital. It contains about 30 beds for intern patients, and a large extern department. The latter is open on Monday,

Wednesday and Friday at 12 o'clock for eye cases, and on Monday and Thursday at 12 o'clock for ear cases. Special courses of instruction are given during the winter and summer sessions, but students can enter at any time, and can always obtain plenty of practice in ophthalmoscopic work. Full particulars may be had from Dr. Cecil Shaw, 29 University Square East, Belfast.

**ROYAL VICTORIA HOSPITAL**.—Established 1791; incorporated by Royal Charter, 1875 and 1898. New hospital opened, September 17th, 1903. 300 beds; Convalescent hospital, 24 beds; Children's Hospital, 33 beds; Consumptive Hospital, 10 beds.

**ULSTER EYE, EAR, AND THROAT HOSPITAL**.—Established 1871. New hospital opened 1874. 30 beds.

**ULSTER HOSPITAL FOR CHILDREN AND WOMEN**, Mountpottinger, Belfast, is the only hospital in the large part of the city situated on the County Down side of the river. It is placed in a working class district, and has a great field for its charitable operations. There are in the hospital about twenty-two beds for children and eight for women. There is an extern department for children open every week-day, except Saturday, from 9 till 10, and for women at 10.30, and a special department for diseases of the eye, ear, and throat on Tuesdays and Fridays from 9 till 10. During the summer and winter sessions, clinical instruction is given to students daily, operations being chiefly performed on Wednesday and Thursday. There is a resident midwife for extern work, and every facility is afforded students for attending their cases in the district.

#### CORK HOSPITALS.

**VICTORIA HOSPITAL FOR WOMEN AND CHILDREN**.—Established 1874. 70 beds. A large amount of work is done in this hospital to relieve the poor of Cork, Kerry, and other counties. A large number of successful operations are done every year. The hospital contains several private rooms for paying patients.

\***COUNTY AND CITY OF CORK LYING-IN HOSPITAL**.—Established 1798. 17 beds.

\***EYE, EAR, AND THROAT HOSPITAL**, Western Road.—Incorporated 1898. 35 beds. In-patients treated during year, 454; out-patients, 4,238. Clinical instruction is given during college session. Special demonstrations in the use of the ophthalmoscope, laryngoscope, &c., are given from time to time.

\***FEVER HOSPITAL AND HOUSE OF RECOVERY**.—Established 1801. 110 beds.

\***MATERNITY**.—Established 1872.

\***MERCY HOSPITAL**.—Established 1857. 80 beds.

\***NORTH CHARITABLE INFIRMARY**.—Established 1774. 110 beds. Special wards for treatment of diseases of women and children. The extern department is largely made use of, and the number of accidents treated is very large. Clinical instruction is given daily from 9.30 a.m. to 12 noon. A new and thoroughly up-to-date operating theatre has recently been added at considerable expense.

**CORK SOUTH INFIRMARY AND COUNTY HOSPITAL**.—Founded 1773. The hospital contains 100 beds, available for clinical instruction, 40 medical and 60 surgical. There are also special wards devoted to the treatment of diseases peculiar to women and children, and a large medical and surgical extern department.

Clinical instruction is given daily during the session from 9.30 to 11.30, in both the medical and surgical wards, and clinical lectures are regularly delivered.

The operation and sterilising rooms are thoroughly up to date. The X-ray department is fully equipped with the newest apparatus necessary for such work. Students are regularly instructed in the methods of using the rays by practical demonstration on the cases requiring their use.

The hospital has been largely availed of by students of the Cork School of Medicine.

#### GALWAY HOSPITALS.

\***COUNTY GALWAY**.—Established 1786. 60 beds.

\*No answer to our request for information received from these hospitals.

## IRISH PUBLIC SERVICES.

## THE POOR-LAW MEDICAL SERVICE.

For several years past the unsatisfactory nature of the Irish Poor-law Medical Service, as a career for young practitioners, has furnished a theme for the opening addresses at the leading medical schools. In addition to the petty annoyances, the laborious and harassing duties, and the ever-increasing amount of clerical work which the new orders of the Local Government Board impose from time to time, the unfortunate medical officers are grievously underpaid, their salaries being totally out of proportion to the duties discharged, and in the majority of rural districts barely sufficient to cover the out-of-pocket expenses, such as are incurred in the keep of a horse and man, and other servants. The Local Government Board have recently laid it down, moreover, that the dispensary patients have the first call on the time of the medical officer, and that, even if he is engaged on an urgent private case, he must give it up and go off to attend on a "scarlet-runner," as the dispensary visiting tickets are not inappropriately called. So strictly is he bound to the discharge of his duties that unless incapacitated by sickness or other cause, or with the permission of the guardians expressly granted, he cannot leave his district for a single day, even if he makes provision for the performance of his duties in his absence by a brother practitioner. The Irish Medical Association, whose work includes the safeguarding of the interests and the improvement of the condition of the Poor-law medical officer, considers it an imperative duty to point out to young practitioners the following facts: (1) That the Poor-law Medical Service is one in which there is no promotion. (2) That it is a service where few facilities exist for original research, and still less for further medical culture, especially in the rural districts. (3) That, while medical education has become wider in its requirements, and more costly and difficult to procure, almost the same rate of payment given to less educated men forty years ago is still offered, and this, too, at a time when the rural prosperity of the country is less, and consequently lucrative private practice more difficult to obtain. (4) That there is no compulsory superannuation, and, as a consequence, many old and infirm men are forced to remain in the service long after they have become unfit to discharge the duties, seeing nothing but extreme poverty and perhaps the workhouse itself staring them in the face.

We need go no further than to say that the Irish Poor-law Medical Service is a service to avoid. We therefore strongly urge on young medical men the importance of supporting the interest of the profession and their own, by refraining from applying for vacant posts of which the salary is insufficient, from accepting posts as *locum tenens* at a lower rate than £4 4s. per week.

There are 159 workhouse and about 810 dispensary medical officers, besides apothecaries. The salary in this service used to average about £114, and when it is taken into consideration that in the vast majority of rural districts it is necessary to keep one or more horses, the average area being from forty to sixty square miles, it is plain that there will not be a large margin left from the public emoluments.

The dispensary medical officer is also *ipso facto* the registrar of births, marriages, and deaths, and medical officer of health for the district, under the Public Health Act, passed in 1873 and amended in 1878. The former office, in country districts, yields between £5 and £10 a year, and the emoluments of the latter appointment in very few cases reach £20, averaging about £12. The medical officer is also vaccinator for the locality, and is required to vaccinate everyone who wishes to come. For each patient a fee of 2s. is paid, along with his salary, by the guardians, and the sum total of those fees varies, according to the populousness of the district, from £4 to £100, an average for the provinces being about £10.

**Qualifications.**—The qualifications required by the Local Government Board are a licence in surgery, in medicine, and in midwifery; but registration in the

"Medical Register," if effected since the passing of the Medical Act, in 1886, fulfils all requirements. The candidate must also be 23 years of age. Candidates recently qualified must possess a certificate of competence in vaccination.

**Duties.**—The duty of the dispensary doctor is twofold. He has to attend his dispensary on a given day or days in the week. Frequently there are two dispensaries in the district, separated from each other by several miles, and he will have, perhaps, to attend two days a week. He has also to visit at any hour of the day or night a sick person for whose relief a visiting ticket has been issued by a guardian, warden, or the relieving officer, and to continue his attendance as often as may be necessary to the termination of the case. Moreover, he has a great many registry books to keep and a multitude of returns to make, and in most districts he has to make up all the medicines for the poor.

**Workhouse Hospitals.**—The number of unions in Ireland is 150, to each of which is attached one or more medical officers, appointed and controlled by the board of guardians in the same manner as the dispensary medical officer. The salary is about the same as that of the dispensary doctor, and the duties of a more easy and satisfactory description, inasmuch as they are confined to daily attendance at the workhouse hospitals, and no night visits out of doors or long journeys across the country are involved.

## THE IRISH LUNACY SERVICE.

This service, at present, affords a comfortable livelihood for 22 Resident Medical Superintendents and 32 Assistants. The Superintendents receive salaries and allowances ranging, according to the number of inmates of the asylum, from £500 to £1,000 a year, and the Assistants receive salaries and emoluments averaging about £200 a year. There are also a few Visiting Physicians receiving about £120 a year, but this class of officer is being allowed to die out, and no new appointments will be made. The Superintendents and Assistants must devote their whole time to their duties.

Formerly the appointments of Medical Superintendents were in the patronage of the Lord Lieutenant, but, under the Local Government Act, they are in the hands of the County Councils, with the proviso that no one shall be appointed who is not a fully registered practitioner with five years' service as Assistant. The Assistant is appointed by the Committee of the County Council to which the management of the asylum is entrusted. In addition to these officers, there are, in certain larger asylums, Clinical Residents, who receive about £50 a year and full allowances. These appointments afford excellent introduction to the higher places in the service.

## OTHER APPOINTMENTS.

There are, in addition to those which we have mentioned, certain appointments open to medical practitioners in special localities. They are:—

- (1) Attendance on the Royal Irish Constabulary.
- (2) Attendance on the Coastguards.
- (3) Factory Surgeoncies.
- (4) Attendance upon the depot soldiers who are not otherwise provided for.
- (5) Attendance on Postal Officials.
- (6) Prison Surgeoncies.

The Constabulary are paid for at the rate of 2s. per month for each member of the force on duty in the district, including the wives and children of the men, but not of the officers. This includes the supply of medicines. The appointment to this position rests with the Inspector-General of the Royal Irish Constabulary, who usually acts upon the advice of the local District Inspectors as to the convenience of the men, and, of course, the emoluments depend on the number of Constabulary stations and the number of men in each.

**The Coastguard Service.**—The duty of the Medical Officer is to attend the men when sick and to examine candidates either for admission or for superannuation. The fees vary from 5s. to 2s. 6d. per visit. The appointments rest with the Admiralty, but are usually secured for the local Poor-law Medical Officer. The emoluments depend on the number of stations and men.

Factory surgeoncies are in the gift of the Chief Inspector of Factories in Whitehall. There is a set

scale of payment by the factory owner to the inspector for this work, but we believe it is not adhered to, and, in some districts, at all events, the emolument is a matter of arrangement. The amount depends upon the size of the factory, the position being, in Dublin or Belfast, or in other large manufacturing centres, a lucrative one, but in other places scarcely worth taking. The attendance on the military depôts is not worth mentioning. Attendance upon postal servants is badly paid, except in the large towns, and the inspecting and sanitary duties are onerous.

Surgeons to the prisons are appointed by the Lord Lieutenant. The salaries for visiting surgeons vary from about £40 a year to £150. In the larger prisons there are whole-time surgeons.

## Scotland.

NOTWITHSTANDING the increased competition which the recent vigorous growth of the great English provincial medical schools, added to the unsurpassed attractions of the historic Metropolitan hospitals, with their staffs of renowned teachers, offer, the Scottish medical schools seem fully to retain their popularity not only, as is natural, among Scotsmen and their colonial descendants, but among medical students from England, Wales, and Ireland, and, indeed, all parts of our Empire. Of the four universities, Edinburgh, of course, occupies the premier position as a medical school, but at Glasgow, Aberdeen, and St. Andrews, an almost equally good—indeed, in individual details, better—training can be obtained. Two ordinary qualifications to practise are granted in Scotland—the M.B., Ch.B. of the Universities, and the triple qualification of the Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow. The examinations for the University degree naturally are more exacting than those for the triple qualification, and the curriculum wider. Nevertheless, the standard for the latter is much higher than formerly, though on account of the large number of examiners in most subjects it is probably slightly less uniform than that of the universities, where the examinations are conducted by the professors with one or more extra-mural assessors in each subject. Two features of the Scottish system deserve mention—first, as regards the co-ordination of various separate teaching bodies in each centre; second, as regards the conditions under which the students live. Around each university there has grown up an extra-mural medical school, in which the teachers are hospital physicians, surgeons, and specialists unconnected with the university, but whose classes qualify for graduation. Thus the student has usually ample choice, and can, within certain limits, attend the teacher from whom he thinks he will derive most benefit, while the extra-mural lecturers, being unendowed and constantly recruited by fresh blood, have a permanent incentive to keep their courses up to the mark, since any slackness is at once followed by a diminution in the number of students' fees. In late years instead of each extra-mural teacher lecturing separately, combinations have been formed, in which different parts of a course on medicine are given by different physicians, and these have proved exceedingly popular and successful. A very important part of the student's clinical work, too, is done at institutions and under teachers quite unconnected with the universities; this is his dispensary

practice, which may be taken at one of several dispensaries situated in the poorer districts of the towns. Owing to lack of material practical training in obstetrics is one of the least satisfactory parts of the teaching in Edinburgh, and many students are in the habit of going to Glasgow or Dublin for their maternity work. Recently, however, steps have been taken which should render this unnecessary, and ought to give Edinburgh students quite sufficient opportunity of acquiring as good a practical acquaintance with this most important subject as they have of obtaining a theoretical knowledge of it. From what has been said it will be seen that university undergraduates and triple qualification men rub shoulders at every turn—in the wards, dispensary, and lecture-room. University students have the privilege of studying under both intra- and extra-mural teachers, while men going up for the triple qualification are limited to the latter. It is not uncommon, therefore, for a man to come up intending to take the licence, and to change his mind and go in for a degree, or *vice versa*; and this can usually be done without much added expense or taking out many fresh classes, provided the change is not made too late in the curriculum. The weak spot in the Edinburgh curriculum is the overcrowding of subjects in certain years, but the new three-term session, with the increased frequency of professional examinations, which came into operation on October, 1907, has done something to remedy this, and paves the way for a better arrangement of the curriculum.

For the rest, the student lives as he likes and where he likes; the authorities only demand that he shall attend classes with due regularity and diligence, and exhibit sufficient proficiency to pass his examinations. Most men live in lodgings, a few board with private families, and some live in the various halls of residence which have been established. In these last, too, the student is his own master, the halls being managed solely by a committee of the residents for the time being. It is impossible to make any very definite statement as to the relative cost of a medical education in the different schools, as compared with London and Dublin, as so much depends on the extra classes taken out, the mode of living, and so on. The minimum inclusive fees for the licence are £120, for the M.B. degree about £145; but almost every student finds it practically necessary to attend additional classes. On the whole, the cost of living is highest in Edinburgh, lowest in Aberdeen; in the former, while the rent of lodgings is lower than in London, maintenance, including clothing and provisions, is somewhat more expensive. Incidental expenses, amusements, &c., are, however, considerably less in the Northern capital. In Aberdeen, money goes much further than in the south, and the student ought to keep himself on about two-thirds of the funds required in Edinburgh.

### THE CARNEGIE TRUST.

Through the munificence of Mr. Andrew Carnegie, LL.D., payment is now made "of the whole or part of the ordinary class fees exigible by the Universities from students of Scottish birth or extraction, and of sixteen years of age or upwards, or scholars who have given two years' attendance, after the age of fourteen years, at State-aided schools in Scotland, or at such other schools and institutions in Scotland as are under the inspection of the Scottish Education Department."

The Trust provides for the payment of the class fees of the above students proceeding to graduation in medicine or science. Application for payment of class fees under the conditions of the Trust should be made to the Secretary, Mr. W. S. McCormick, Merchants' Hall, Edinburgh.

### UNIVERSITY OF EDINBURGH.

Four degrees in medicine are granted; Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The first two must be taken together, the last two may be taken separately.

No one is admitted to the degrees of Bachelor of Medicine and Bachelor of Surgery who has not

been engaged in medical study for five years, after passing a preliminary examination in general knowledge in accordance with the medical ordinances. A degree in Arts or Science of a British or other recognised University is held to supersede such preliminary examination. The subjects included in this general examination are English, Latin, elementary mathematics, and Greek, or French, or German.

The *annus medicus* of each year is constituted by at least two courses of not less than one hundred lectures each, or by one of such courses, and two courses of not less than fifty lectures each, exclusive of the clinical courses. Two years of the five must be spent at the University, the remaining three years at any other Medical School recognised by the University Court.

During the first four years the student must attend botany, zoology, physics, practical chemistry, practical physiology, practical pathology, and medical jurisprudence during courses of not less than 2½ months each; public health, not less than forty lectures; practical anatomy, during two courses of not less than five months each; chemistry, anatomy, physiology, pathology, surgery, materia medica, medicine and midwifery during courses of not less than five months each. He must attend a course of twenty-five lectures on practical pharmacy, or have dispensed drugs for a period of three months in a recognised hospital or dispensary. He must attend a nine months' course in clinical medicine and in clinical surgery. During the fifth or final year he must be engaged in clinical study for at least nine months. In all, before graduation, he must have done hospital work for at least three years, and have acted as clerk in the medical and surgical wards and attended for six months the practice of a dispensary, or of a physician and surgeon. He must also have studied (1) operative surgery; (2) mental diseases; (3) *post-mortems*, fevers, and diseases of the eye, and (4) one of the following: Diseases of children, of the ear, nose and throat, or of the skin; (5) vaccination; (6) practical anaesthetics.

He must attend at least 25 cases of labour under the superintendence of a registered medical practitioner or 12 such cases, and, for at least three months, the practice of a midwifery hospital.

Each candidate is examined both in writing and *viva voce*—

1. On zoology, botany, physics and chemistry.
2. On anatomy and physiology.
3. On pathology, and materia medica and therapeutics.
4. On medicine, surgery, midwifery, forensic medicine, and public health.

On October 1st, 1907, a new division of the medical curriculum was inaugurated, the year being divided into three sessions, a 1st winter, a 2nd winter, and a summer session. At the end of each of these professional examinations are held, instead of twice yearly as formerly.

The new order of examination (for students beginning in winter) is as follows:—Physics, end of first half of first winter; Chemistry, end of second half of first winter; Zoology and botany, end of first summer; Physiology, end of second summer; Anatomy, end of first half of third winter; Practical materia medica, end of second half of third winter; Pathology, end of third summer; Materia medica, end of second half of fourth winter; Medical jurisprudence and public health, end of fourth summer; Midwifery, end of first half of second winter; Medicine and surgery, end of second half of second winter; Clinical medicine, surgery and gynaecology, end of fifth summer.

The degree of Doctor of Medicine may be conferred on any Bachelor of Medicine and Bachelor of Surgery, and who is of the age of twenty-four years, and who produces a certificate of having been engaged, subsequently to his having received the degrees of M.B. and Ch.B., for one year in attendance on a hospital, or in scientific work bearing directly on his profession, or in the military or naval medical services, or for two years in practice other than purely

surgical. The candidate shall submit to the Faculty of Medicine a thesis on any branch of knowledge comprised in the professional examinations for the degrees of Bachelor of Medicine and Bachelor in Surgery. The candidate will also be examined in clinical medicine and must show practical acquaintance with advanced methods of diagnosis; he may take gynaecology, mental diseases, or diseases of children for one of his three cases. The degree of M.D. is conferred on holders of the degrees of M.B., Ch.B. (Old Regulations) on the submission of a thesis approved by the Medical Faculty, provided that the candidate has passed the preliminary examination in the subjects of Greek and logic or moral philosophy. Should the candidate elect to do so, he may, however, take the M.D. degree under the new regulations, *i.e.*, substituting an examination in clinical medicine for that in Greek and logic. This course is usually pursued by those who did not pass in these subjects with the rest of their preliminary examinations.

The regulations for the degree of Ch.M. are very similar.

**Fees**:—The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery is twenty-two guineas. The fee for the degree of Doctor of Medicine or of Master of Surgery is ten guineas (Old Regulations, £5 5s.).

The total expense of the curriculum, including examination and matriculation fee, is £146.

Among scholarships, &c., open for competition during the session 1909-10 are the following:—Vans Dunlop scholarship, value £100, in preliminary subjects. Stark scholarship in clinical medicine, value £110; Buchanan scholarship in midwifery, value £40; Mouat scholarship in practice of physic, £57; Syme Surgical Fellowship, £120 for two years; Goodsir Memorial Fellowship, £102 for two years; Freeland Barbour Fellowship, £105. There are also a great many other bursaries, Fellowships and prizes open during the session of 1909-10 and for the details governing entry for these the University Calendar (James Thin, South Bridge, Edinburgh) should be referred to.

Graduation in Public Health: Degrees (B.Sc. & D.Sc.) are also conferred in Public Health. Candidates must be graduates in medicine and must matriculate for the year in which they proceed for examination. They must (1) have worked at least twenty hours a week during a period of eight months in a recognised Public Health laboratory—five of these months must be spent consecutively in the Public Health Laboratory of the University of Edinburgh; and (2) have attended a course of lectures on physics in addition to that qualifying for graduation in medicine, and one on geology.

Candidates for the second examination are not admitted until eighteen months have elapsed after having passed M.B., Ch.B., or sooner than six months after the first examination. They must have attended two courses of Public Health, one dealing with medicine, the other with engineering in relation to public health. They must also have studied practical sanitary work under a Medical Officer of Health for six months, have had three months' instruction in a fever hospital, and three months' instruction in mensuration and drawing.

**Fees for Science Degrees**: B.Sc., first examination, £3 3s.; B.Sc., second examination, £3 3s.

**Diploma of Tropical Medicine**.—Every year an increasing number of candidates avail themselves of the University Diploma of Tropical Medicine and Hygiene, which is conferred only on those possessing a degree in medicine. The course includes practical bacteriology, tropical diseases and hygiene, the zoological character and life history of disease-carrying insects and venomous animals, clinical instruction at an hospital for tropical diseases. The examination is held in January and July, the fee being £4 4s.

**University Hall, Edinburgh**.—In an educational number it is worth while calling attention to the advantages now offered to students coming to Edinburgh to study, in the shape of social residences,

in which students can live in a self-governing community. In each house there are private studies with or without bedrooms, and common sitting and dining rooms. The charges vary from 7s. 6d. to 22s. 6d. per week. The residents elect a treasurer from among their number who acts as intermediary between them and the housekeeper or servants. It is a satisfactory indication of the comfort of the Hall that many graduates live in it and are willing to help or coach the undergraduates for moderate fees. To gain admission two references must be produced from past or present residents, or other suitable person. These are considered and voted on at a house meeting. The Hall is an admirable place for parents to send their sons to. Any unruly member may be expelled by a meeting of the residents similar to that held for elective purposes.

**Medical School for Women.**—Classes for women are carried on in the College of Surgeons and the New School, by Lecturers recognised by the University.

Information may be obtained, on application to the Dean, School of Medicine of the Royal Colleges, College of Surgeons, Edinburgh. Session begins October 1st, 1900. The classes qualify both for the Edinburgh University degree and for the Licence of the Triple Board, and are for women alone. The University of Edinburgh does not recognise certificates presented by female candidates for mixed classes without special cause shown. Women students are eligible for the benefits of the Carnegie Bequest.

#### UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and an examining body, but admits to examination only those candidates whose course conforms to its own regulations. Within certain limits provision is made for accepting instruction given by recognised medical schools and teachers; but eight of the subjects other than clinical must be taken in this or some other recognised University entitled to confer the degree of M.D., and at least two years of the course must be taken in Glasgow University. Under the new regulations, laid down in Ordinance No. 14, Glasgow No. 1, of the Commissioners under the Universities (Scotland) Act, 1889, four degrees, open both to men and to women, are conferred—M.B. and Ch.B. (always conjointly), M.D. and Ch.M. A preliminary examination must be passed in (1) English, (2) Latin, (3) Elementary mathematics, and (4) Greek, French, or German, with possible option to students whose native tongue is not English in the case of the fourth subject, and, on passing, students must register in the books of the General Medical Council. By a regulation recently enacted, it is no longer compulsory to pass in all the four preliminary subjects at once, and they may now be passed at two stages. For M.B. and Ch.B. a curriculum of five years is required. A syllabus with full details of the curriculum and of the preliminary examination may be had, post free, on application to the assistant clerk, Matriculation Office.

The fees for M.B. and Ch.B. are £23 2s.; for M.D. £10 10s., and for Ch.M. £10 10s. For hospital attendance there is an initial fee of £10 10s., with a further fee of £3 3s. for each winter session, and £2 2s. for each summer session, of clinical instruction. There are three very extensive general hospitals in the city, which afford exceptional opportunities for clinical work, while the Royal and other asylums, the City Fever Hospitals, the Maternity Hospital, the Sick Children's Hospital, the Eye Infirmary, &c., give facilities for the study of special branches.

The degrees of B.Sc. and D.Sc. in Public Health and of B.Sc. in Pharmacy, are also now conferred. Of late the University has made considerable efforts to extend its laboratory accommodation and equipment, to augment its teaching staff, and to encourage post-graduate and research work. Within recent years there have been provided new laboratories in the departments of pathology, anatomy (costing £13,000), chemistry, and surgery (costing £9,900); while new laboratories, to cost, with equipment, upwards of £50,000, have been erected

for the departments of physiology, materia medica, and medical jurisprudence and public health.

Bursaries and prizes to the annual amount of about £1,000 are appropriated to medical students, including an Arthur bursary for women, £20 for three years.

Several bursaries open to students in any faculty are not infrequently held by medical students, and Scholarships and Fellowships to the annual amount of £1,600 may be held by medical students who have gone through the Arts course.

**Queen Margaret College for Women.**—Founded in 1883 (by the Glasgow Association for the Higher Education of Women, which was formed in 1877 with the object of bringing University instruction, or its equivalent, within the reach of women), Queen Margaret College in 1890 added to its faculty of Arts a School of Medicine for Women. This was organised entirely on University lines, and with the view of preparing for University degrees; and when, in 1892, in consequence of the Ordinance of the University Commissioners authorising the Scottish Universities to admit women to instruction and graduation, Queen Margaret College became the Women's Department of the University of Glasgow, its classes in medicine taken previously to its incorporation with the University were recognised as preparing for the degree. A full course of study for M.B. and Ch.B. is given by University professors and lecturers, with excellent facilities for hospital and dispensary work in the Royal Infirmary and other hospitals. A Hall of Residence for the students was founded in 1894. Fees for the classes at Queen Margaret College may be paid by the Carnegie Trustees; and several bursaries are open to women students of medicine.

The Winter Session begins on 11th October. The prospectus can be obtained from the Mistress, Miss Melville, Queen Margaret College, Glasgow.

#### UNIVERSITY OF ABERDEEN.

The University of Aberdeen possesses under its charters the amplest privileges claimed or enjoyed by any academical institution. It confers degrees in the five faculties of Arts, Science, Divinity, Law, and Medicine. It also grants diplomas in Public Health, Agriculture, and in Education. It is, moreover, a teaching body equipped with twelve distinct chairs in the various branches of medicine and surgery. The majority of the professors devote their whole time to the work of the chairs. There are fully-equipped laboratories, the accommodation for which has recently undergone considerable extension. The degrees of M.B. and Ch.B. are conferred together; they cannot be obtained separately. The curriculum of study is nearly the same as in the University of Glasgow; the regulations in the preceding columns will therefore apply here. Two years must be passed at Aberdeen. With regard to fees, each candidate for the degrees of M.B. and Ch.B. must pay a fee of £5 5s. in respect of each of the first three professional examinations, and £7 7s. for the final examination. Total cost, exclusive of the fees for degrees, is about £120. Besides the Royal Infirmary, students have the opportunity of attending several other local institutions where special courses of instruction are given. Perpetual fee for hospital practice is only £6. The professional examinations are held twice in each year, namely, in March and July, directly after the close of the winter and summer sessions.

**BURSARIES.**—Bursaries, Scholarships, and Fellowships to the number of fifty, and of the annual value of over £1,180, may be held by students of medicine. (See "University Calendar.")

**THE DEGREE OF M.D.**—The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degrees of M.B. and C.M. (Old Regulations), is of the age of twenty-four years, and has been engaged subsequently to his having received the degree of M.B. for two years in attendance in a hospital, or in military or naval medical service, or in medical or surgical practice, and has presented a thesis which has been approved of by the Medical Faculty. Candidates for the degree of M.D. (New Regulations) are required to pass an examination in clinical medicine in addition

to presenting a thesis. Similar regulations apply to a degree of Ch.M. (Master of Surgery).

A Diploma in Public Health is conferred after examination on graduates in medicine in any University in the United Kingdom. Regulations may be seen in the "Calendar," or obtained on application to the Secretary of the University.

**Aberdeen Royal Infirmary.**—This is a well-equipped institution, containing 250 beds, and affords excellent opportunities for clinical study to students at the Aberdeen University. The city, moreover, offers inducement in the way of cheaper living and comparative quiet to that obtained in Edinburgh and Glasgow, and will doubtless be preferred by some on this account.

#### ST. ANDREWS UNIVERSITY.

UNITED COLLEGE, ST. ANDREWS, AND UNIVERSITY COLLEGE, DUNDEE.

This University (session opens October 7th) grants the degrees of M.B., Ch.B., M.D., and Ch.M. The degrees of the University are open to either sex. For the degree of M.B., Ch.B., two of the five years of medical study must be spent in the University of St. Andrews; the remaining three may be spent in any University of the United Kingdom, or in any foreign, Indian, or Colonial University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. The preliminary examination and the professional examinations are of the same character as in the other Scottish Universities. A Diploma in Public Health is also granted by the University of St. Andrews to graduates in medicine of any University in the United Kingdom. Twelve months must elapse between the date of graduating in medicine and entering for the examinations for the diploma. The course of study required consists of (1) a six months' course of practical chemistry, bacteriology, and the pathology of diseases transmissible from animals to man in a laboratory of the University of St. Andrews; (2) six months' work with a medical officer of health; (3) three months' clinical instruction in infectious diseases. Subjects for first examination:—Chemistry, physics, bacteriology, and meteorology. Second examination:—Sanitation, sanitary law, vital statistics, medicine in relation to public health.

*University College, Dundee*, was affiliated and made to form part of the University of St. Andrews on January 15th, 1897, and the whole medical curriculum may be taken at the medical school (accommodated in a large new building) of that College. The United College, St. Andrews, offers classes for the first two years of professional study.

#### BURSARIES AND SCHOLARSHIPS.

**United College, St. Andrews.**—Malcolm bursary, £25 a year, tenable for five years. Fourteen Taylour Thomson bursaries, £30 to £20, five tenable for one year, nine for two, open to women only proceeding to graduate in medicine. Fourteen bursaries open to competition by entrance students may be held by students of medicine.

**University College, Dundee.**—Eleven entrance bursaries of £15, open to women for arts, science, or medicine, tenable for one year. Four £20 and three £15 second year bursaries for men or women in arts, science, or medicine, tenable for one year. Four £20 and two £15 third year bursaries for men or women in arts, science, or medicine, tenable for one year, and two £20 bursaries for fourth and fifth year medical students. Two Educational Trust bursaries of £25, tenable for three years. Applicants must have attended a public or State-aided school in Dundee for at least one year before examination. Bute bursary, annual income from £1,000 (men only).

**Preliminary Examinations.**—The dates of the next two examinations are September 10th, 1909, and March 24th, 1910. Schedules (obtainable from the Secretary of the University) to be returned filled up, and fees paid by September 1st, 1909, or March 12th, 1910.

**Fees for Degrees.**—Total fees for M.B., Ch.B., are the same as at other Scottish Universities, i.e., 22 guineas (payable in instalments). Fee for the degree of M.D.,

and also for that of Ch.M., is 10 guineas in each case. For the Diploma of Public Health examinations the fee is £5 5s. for each of the two examinations.

**Class Fees.**—The fee payable in each of the following classes is 4 guineas, viz.:—Chemistry, physics, zoology, botany, physiology, anatomy, materia medica, pathology, forensic medicine, and public health, medicine, surgery, and midwifery. The fee for the practical classes in these subjects is 3 guineas each. In clinical surgery, clinical medicine, ophthalmology, diseases of the throat, nose, and ear, diseases of the skin, and mental diseases, the class fees are 2 guineas each. The fee for Public Health chemistry required for the D.P.H. is 7 guineas. A special class in Bacteriology is also held for the D.P.H. for which the fee is 3 guineas.

**Dundee District Asylum.**—The appointments includes two qualified resident assistants and two resident clinical clerks. Clinical instruction is given.

**Dundee Royal Infirmary.**—The Infirmary contains 400 beds, with an annual average number of over 4,000 in-patients, and an annual daily residence of 280, with special wards for maternity cases, diseases of women, diseases of children, diseases of the eye, diseases of the ear, throat and nose, cancer, and for cases requiring electric treatment. Five resident qualified assistants and an outdoor obstetric assistant are appointed annually. Clinical clerks and dressers are attached to the physicians and surgeons, and students are appointed to assist in the post-mortem room. Out-patients are seen daily at 9 a.m. The instruction given at the Infirmary is recognised for purposes of graduation by the Scotch Universities, the University of London, the University of Cambridge, the Royal University of Ireland, and by the Royal Colleges of England and Scotland. Hospital Tickets for the Infirmary, £2 2s. each session, or £3 3s. a year. Perpetual, £10 in one payment, or £10 10s. by instalments.

Further information will be found in the Calendar of the university published by Messrs. Blackwood and Sons, Edinburgh, the "Calendar of University College," Dundee (obtainable from the Secretary), or can be had from the Dean of the Medical Faculty, Professor I. A. Kynoch. (See advertisement page.)

#### THE COLLEGES.

The Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow have arrangements by which the student may obtain the diploma of the co-operating bodies, and can register three diplomas under the Medical Acts, viz., Licentiate of the Royal College of Physicians of Edinburgh, Licentiate of the Royal College of Surgeons of Edinburgh, and Licentiate of the Faculty of Physicians and Surgeons of Glasgow.

The three bodies grant their *single* qualifications only to candidates who are already registered as possessing another and opposite qualification in medicine and surgery as the case may be.

**REGULATIONS OF THE CONJOINT BOARD OF THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH AND THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH AND THE FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW.**—The candidate must produce certificates of having attended the following course of lectures, the certificate distinguishing the sessions and the schools in which the courses were attended. Anatomy, six months; practical anatomy, twelve months; chemistry, six months; practical chemistry, three months; materia medica, three months; physiology, six months; medicine, six months; clinical medicine, nine months; surgery, six months; clinical surgery, nine months; midwifery, three months; medical jurisprudence, three months; pathology, three months. The candidates must also produce the following certificates:—(a) Of having attended six cases of labour under the superintendence of a registered practitioner. (b) Of having attended for three months' instruction in practical pharmacy. The teacher must be a member of the Pharmaceutical Society of Great Britain, or the Superintendent of a laboratory of a public hospital

or dispensary, or a registered practitioner, or a teacher to a class of practical pharmacy. (c) Of having attended for twenty-four months the medical and surgical practice of a hospital, containing eighty patients, and possessing distinct staffs of physicians and surgeons. (d) Of having attended for six months the practice of a public dispensary, or of having assisted for six months a registered practitioner. (e) Of having been instructed in vaccination.

**First Examination, Fee £5.**—The first examination shall embrace chemistry, physics, and elementary biology, and shall take place not sooner than the end of the first year, including a winter and summer session. Candidates who desire to enter for the first professional examination must produce certificates of attendance on chemistry, practical chemistry, anatomy, and six months' practical anatomy.

**Second Examination, Fee £5.**—The second examination embraces anatomy and physiology and shall not take place before the termination of the summer session of the second year of study. Candidates must produce certificates of attendance on anatomy, practical anatomy, and physiology.

**Third Examination, Fee £5.**—Comprises the subjects of pathology, materia medica, and pharmacology and advanced anatomy.

**Final Examination, Fee £15.**—The final examination embraces medicine (including therapeutics and medical anatomy, clinical medicine); surgery (including surgical anatomy and surgical pathology); clinical surgery; midwifery and gynaecology, medical jurisprudence and hygiene; and shall not take place before the termination of the full period of study.

Subjects of Preliminary Education: (1) English grammar and composition; (2) Latin, grammar, translation from specific authors and easy unseen translation; (3) (a) arithmetic, to vulgar and decimal fractions; (b) algebra, to simple equations; (c) geometry, to the first two books of Euclid; (4) elementary mechanics of solids and fluids, comprising the elements of statics, dynamics, and hydrostatics; (5) one of the following:—(a) Greek; (b) French; (c) German; (d) Italian; (e) any other modern language; (f) logic; (g) botany; (h) zoology; (i) elementary chemistry.

**Qualification in Public Health:** The College of Physicians, in association with the Royal College of Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, confers a certificate of competency in public health. The examinations are held in April and October. Fee, £10 10s.

For the special regulations of the Royal College of Surgeons of Edinburgh, intending candidates should apply to Mr. James Robertson, 48 George Square, Edinburgh; and for those of the Royal College of Physicians, to the Secretary.

The Fellowship of the Royal College of Physicians of Edinburgh is conferred only by election, and the candidate must have been a member of the college for at least three years, and have attained the age of twenty-seven years.

The Membership is conferred only on a licentiate of a college of physicians or graduate in medicine of a British or Irish University, provided he shall have attained the age of twenty-four years and shall have passed an examination on: (1) medicine, including therapeutics (2) on one of the following optional subjects, in which a high standard of proficiency is expected:—(a) a department of medicine specially professed; (b) psychological medicine; (c) pathology; (d) medical jurisprudence; (e) public health; (f) midwifery; (g) gynaecology. The examination is of a searching character.

The fee for membership is 35 guineas, for fellowship 38 guineas, with a stamp duty of £25—£101 13s. in all.

The licence, or single qualification in medicine, is conferred on candidates who already possess a recognised qualification in surgery. The examinations for this licence are held on the first Wednesday of each month, save those of September and October, in medicine, materia medica, midwifery, and medical jurisprudence. The fee is £15 15s., and intending candidates should communicate with the Secretary of the College at least eight days before the date of examination.

The Fellowship of the Royal College of Surgeons of Edinburgh is conferred (except under certain conditions as to age and professional standing) only on candidates who have passed a special examination, and have previously obtained a diploma from the college, or from either of the Colleges of Surgeons of England or Ireland, or the Faculty of Physicians and Surgeons of Glasgow, or the surgical degrees of the Universities of Great Britain, and who are twenty-five years of age. The subjects for examination for those who are already Licentiates of the College are on the principles and practice of surgery, clinical and operative surgery, and one optional subject.

Those who are not Licentiates of this College: on principles and practice of surgery, clinical and operative surgery, surgical anatomy, and one optional subject; and in such supplementary subjects as have not, in an adequate manner, been included in the examination for the registrable surgical qualification possessed by such candidates, and which are required in the examination for Licentiates of this College.

The optional subjects shall embrace: (a) Surgery, special branches; (b) advanced anatomy and physiology; (c) surgical pathology and morbid anatomy; (d) midwifery and gynaecological medicine and surgery; (e) medical jurisprudence and hygiene; (f) practice of medicine and therapeutics. The examinations are written, oral, and practical. Three weeks' notice must be given to Mr. James Robertson, from whom full particulars as to certificates required may be obtained. The fee is £30 for those who hold the diploma of Licentiate of the College, and £45 to others (no stamp duty is payable on the diploma). Registered practitioners, aged not less than 40, who have been in practice for not less than ten years, and who have highly distinguished themselves by original investigations, may under special circumstances be elected without examination. Women are not admitted to the Fellowship of either college.

**LICENCE.**—The examination embraces the principles and practice of surgery (including operative surgery and surgical pathology), clinical surgery, and surgical anatomy, and shall not take place before the termination of the full period of study. Fee, £15 15s.

**DENTAL DIPLOMA.**—Every candidate for the dental diploma must have attended the general lectures and courses of instruction required at a University or an established medical or dental school recognised by the College as qualifying for the diploma in surgery. The fee is £10 10s.

**Edinburgh Royal Infirmary.**—Clinical instruction is afforded at this institution, which contains 900 beds under the supervision of professors of the University and the ordinary physicians and surgeons of the Infirmary. Special instruction is given on diseases of women, physical diagnosis, diseases of the skin, eye, ear, throat and teeth, and anaesthetics. Separate wards are devoted to venereal diseases, diseases of women, diseases of the eye, also to cases of incidental delirium or insanity, and three wards are specially set apart for clinical instruction to women students. Post-mortem examinations are conducted in the anatomical theatre by the pathologists. The perpetual fee, on one payment, £12; the annual fee, £6 6s.; half-yearly, £4 4s.; quarterly, £2 2s.; monthly, £1 1s. Separate tickets amounting to £12 12s. entitle the student to a perpetual ticket. No fees are payable for any surgical or medical appointment.

The appointments are as follow:—

1. Resident physicians and surgeons are appointed and live in the house free of charge. There is no salary. The appointment is for six months.

2. Non-resident physicians and surgeons (in the special subjects and for out-patient work) are appointed for six months. These appointments may be renewed.

3. Clerks and dressers are appointed by the surgeons and physicians. These are open to all students and junior physicians holding hospital tickets.

4. Assistants in the pathological department are appointed by the pathologists to conduct post-mortem examinations in the anatomical theatre.

**ROYAL HOSPITAL FOR SICK CHILDREN.**—During the

year three courses of clinical instruction are given by the staff of the hospital, who are recognised as University Lecturers on the subject. The course consists of clinical lectures, ward clinics, attendance at *post mortems* and out-patient clinics. Hospital tickets, £1 1s.

#### SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, EDINBURGH.

The government of this school, established in 1505, is now vested in a board which is equally representative of the two Royal Colleges and the Lecturers, the school being styled "The School of Medicine of the Royal Colleges, Edinburgh." The present number of lecturers is about sixty, of whom the greater number deliver qualifying courses of instruction of the same duration and scope as those delivered within the University, while a large number of non-qualifying courses on special subjects of interest to medical science, but which are not required for graduation, are delivered both in the winter and summer sessions. The students who attend the classes of the School of Medicine are largely students proceeding to the University degree, as well as those who are intending to take other qualifications, such as the triple qualification of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow; that of the Royal College of Physicians of London, and the Royal College of Surgeons of England, and the degrees of the different Universities. The number of students attending the school averages 1,300 annually. For particulars apply to the Dean of the School, Royal College of Surgeons, Edinburgh.

The minimum cost of the education in the School of Medicine for the triple qualification of physician and surgeon from the Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, including the fees for the joint examinations, is about £120, which is payable by yearly instalments during the period of study.

The Winter Session opens October 3rd.

#### GLASGOW EXTRA-MURAL SCHOOL.

**St. Mungo's College and Glasgow Royal Infirmary.**—This college was incorporated in 1889 under its new title, being formerly known as the Glasgow Royal Infirmary School of Medicine. The Medical Faculty occupies buildings erected for the purpose of the medical school in the grounds of the hospital, and the laboratories, museums, and lecture rooms are of the most approved description. The college has been recently equipped with a complete electric light installation, and a powerful electric educational lantern. Attendance on the classes in St. Mungo's College qualifies for the medical degrees of the Universities and the medical and surgical colleges in accordance with their regulations.

The Royal Infirmary, which is at the service of the College for teaching purposes, is one of the largest general hospitals in the kingdom. It has over 600 beds available for clinical instruction, including an ophthalmic department, and it has special wards for diseases peculiar to women, for venereal diseases, burns, and diseases of the throat, nose, and ear. At the dispensary special advice and treatment are given in diseases of the eye, ear, teeth, and skin, in addition to the large and varied number of ordinary medical and surgical cases which in a great industrial centre daily require attention. Students at the college and hospital get the benefit of dispensary experience free of charge, and no better or wider field for seeing hospital practice and receiving clinical experience can be found than in the Glasgow Royal Infirmary.

**Appointments.**—All appointments are open. There are five physicians' and eight surgeons' assistants, who obtain free board and residence in the hospital and act in the capacity of house physicians and house surgeons. There is also a house surgeon for the ophthalmic department. These appointments are made for six months, and are open to gentlemen who have a legal qualification in medicine and

surgery. Clerks and dressers are appointed by the visiting physicians and surgeons. From the large number of cases of acute diseases and accidents of varied character received, these appointments are valuable to students. In the pathological department assistants are also appointed by the pathologist.

**Fees.**—The fees for Lectures, including hospital attendance necessary for candidates for the Diplomas of the English, Scotch, and Irish Colleges of Physicians and Surgeons, amount to about £70.

**Royal Infirmary.**—Fees: Hospital practice and clinical instruction, first year, £10 10s.; second year, £10 10s.; afterwards free. Six months, £6 6s.; three months, £4 4s.; pathology, both courses, £4 4s.; vaccination fee, £1 1s.

**Dental Curriculum.**—Students studying with a view to the dental diploma can obtain instruction in the following subjects: Physics, chemistry, anatomy, physiology, surgery, practice of medicine, and materia medica. The special dental courses may be obtained in the Dental School, 15 Dalhousie Street, Glasgow. Particulars may be had from D. M. Alexander, Esq., 97 West Regent Street.

**Anderson's College Medical School, Glasgow.**—The College was founded in the eighteenth century. The modern, excellently equipped buildings are situated in Dumbarton Road, immediately to the west of the entrance to the Western Infirmary, and within four minutes' walk of the University. Extensive laboratory accommodation is provided for practical anatomy, practical chemistry, practical botany, practical zoology, practical physiology, practical pharmacy, operative surgery and public health. Ample provision has also been made for the comfort of students. The buildings are constructed upon the most approved modern principles. The dissecting room is open in winter from 9 a.m. to 6 p.m., and in summer from 6 a.m. to 6 p.m. The students are assisted in their dissections by the professor and demonstrators, by whom daily examinations and demonstrations on the parts dissected are conducted. The supply of subjects is ample, and students are consequently provided with parts as soon as they may be ready for them. The dissecting room is provided with a complete series of dissecting specimens mounted in plaster of Paris illustrating the anatomy of the human body. There is also a large Bone Room, furnished with complete sets of painted and unpainted bones.

The various courses of instruction qualify for all the Licensing Boards in the United Kingdom, and for the Universities of London, Durham, Ireland, Edinburgh, and Glasgow, under certain conditions. The courses in public health (laboratory and lectures) are also recognised by the University of Cambridge. Session opens October 12th, 1908. For syllabus, apply to the Secretary of the Medical Faculty, Anderson's College Medical School, Glasgow, W.

The Carnegie Trust pays the fees of students at Anderson's College on conditions regarding which particulars may be obtained from W. S. McCormick, Esq., LL.D., Carnegie Trust Offices, Edinburgh.

**Class Fees.**—For each course of lectures (anatomy, ophthalmic medicine and surgery, aural surgery, diseases of throat and nose, mental diseases, and public health excepted), first session, £2 2s.; second session (in Anderson's College), £1 1s. For practical classes (except anatomy, chemistry, and public health), namely, botany, zoology, physiology, pharmacy, operative surgery, first session, £2 2s.; second session, £2 2s. **Chemistry.**—Lectures, £2 2s.; practical chemistry, £3 3s. **Botany and Zoology.**—Reduced fees for lectures with laboratory work in botany or in zoology, during same summer session, £3 3s.; for lecture class or practical class separately, in botany or in zoology, £2 2s. **Ophthalmic Medicine and Surgery** (including hospital practice), aural surgery, diseases of throat and nose, and mental diseases, fee for each course, £1 1s. **Anatomy Class Fees.**—Winter.—First session, lectures and practical anatomy, £5 5s.; practical anatomy alone, £2 2s. Second session, lectures and practical anatomy, £5 5s.; practical anatomy alone, £2 2s. Third session, practical anatomy,

£1 1s. Summer.—Lectures and practical anatomy, £2 12s. 6d.; lectures alone, £1 11s. 6d.; practical anatomy alone, £1 11s. 6d.; osteology and practical anatomy, £2 12s. 6d.; osteology alone, £1 11s. 6d.; practical anatomy alone, £1 11s. 6d. *Public Health Laboratory*.—Fee for six months' course, £12 12s. *Matriculation Fee*.—For the year, 10s.; for one class alone in winter, 5s.; for summer session alone, 5s.

**Glasgow Maternity and Women's Hospital.**—This institution is of ancient foundation, but the present buildings, containing 114 beds, with a large out-patient department, were only opened last year. Erected with due regard for the most modern requirements, and staffed by physicians of reputation, it affords excellent facilities for acquiring a complete knowledge of the art and practice of obstetrics. There is also a students' residence in connection with the hospital, in which board and residence can be had at very moderate fees. The hospital fee for three months is £3 3s., and £2 2s. for nine months immediately following.

Glasgow can boast of several other important medical institutions, such as the Western Infirmary, with a staff representative of the best in medicine and surgery of the second city of the Empire, and having no fewer than 500 beds. There is also the Victoria Infirmary, with 260 beds, in which leading specialities, such as ophthalmology, aural surgery, diseases of the throat, diseases of women, diseases of the skin, etc., are taught; the Glasgow Eye Infirmary, with 100 beds; the Royal Hospital for Sick Children, with 74 beds, etc.

## CORRESPONDENCE.

### FROM OUR SPECIAL CORRESPONDENTS ABROAD.

#### FRANCE.

Paris, Sept. 5th, 1909.

#### ECZEMA AND TAR.

THE treatment of certain dermatoses, and of eczema in particular, by the application of crude tar, is strongly recommended by Prof. Broca, of Paris.

Empirics employed this remedy for years, and sailors know that by painting the parts with tar they obtain considerable relief in local pruritus, while in certain parts of Brittany eczematous eruptions are constantly treated by this agent.

As everyone knows, there are two varieties of tar—vegetal tar, resulting from the distillation of wood, turf, etc., and tar from coal, or coal tar; this latter is alone used by Prof. Broca as a topical application for eczema.

Before using the tar, it should be well washed in distilled water to remove all traces of potash and ammonia constantly present, and which would be very irritating to the skin.

According to Leistikow, tar belongs to the class of reducing agents resembling in its effects pyrogallol acid, and, like it, possesses keratoplastic properties. It softens the thick, horny layer, diminishes the formation of squamæ, dries the surface, is a strong astringent for the papillary vessels, and suppresses pruritus by its influence on the terminal nerves.

The method employed by Prof. Broca is as follows: The affected region is first carefully cleaned as far as possible. Where the eczema is moist, covered with crusts or squamæ, a wet compress of some slightly antiseptic solution (boric acid) is applied for 24 or 48 hours, or longer if necessary. An application of zinc or ichthylol ointment might meet the same requirement; in case of pustulæ they are opened and cauterised with a solution of nitrate of silver.

When the surface is by these means well cleaned, a thick layer of coal tar is painted on the whole surface and left to dry. This is one of the important points of the treatment; the longer it is left to dry—one, two, or three hours, as tar dries very slowly—the better the effect of the agent.

When sufficiently dry the parts are powdered with talc and covered with a piece of fine linen. No oil silk should be applied.

Where the skin is not too much inflamed, and the oozing not too great, the dressing may be left two days, and if at the end of that time the aspect of the tegument is satisfactory, and no burning sensation nor itching is complained of, the powder may be continued until all trace of the tar has disappeared, after which, and if necessary, a new application may be made. But if the teguments are very inflamed, and the oozing very abundant, and the patient complains of burning, lancinating pains, or itching, zinc ointment should be applied after the second day of the coating of tar, for four or five days, when the tar may be renewed.

The patient should be warned of the extreme adherence of this substance, and the advantage of allowing it to eliminate spontaneously.

The three great advantages of tar are: it dries the oozing surface, modifies and relieves the redness and tumefaction, and suppresses for a time the itching.

#### TREATMENT OF SYPHILIS (BY PROF. GRANCHER).

Three drugs compose the treatment of syphilis:—

Mercury.

Iodide of potassium.

Sulphur.

*Mercury*.—Soluble solutions should be employed, in virtue of the old adage, *corpora non agunt nisi soluta*. Mercury can be absorbed either by the mouth or by the skin; by the mouth in the form of corrosive sublimate or of a solution of lactate of mercury.

Corrosive sublimate, 1/5th gr.

Ext. of opium, 1/5th gr.

Excipient, q.s.

For one pill; two daily, or, in grave cases, three.

For children, and for adults who cannot swallow pills, a solution of lactate of mercury (1—1,000) should be used. The dose is 10 drops twice or three times a day for children, while adults may take 5 teaspoonsful daily. By the skin, solutions of benzoate or bi-iodide of mercury should be employed, of which different formulæ exist; the latter is the more painful. As these substances are much more rapid in their effects when introduced hypodermically, they should be used in all syphilitic manifestations where it is necessary to act quickly and energetically.

Many advocate grey oil, but, for Prof. Grancher, it is dangerous, as it has provoked more than once gangrene of the mouth, terminating in some cases in death. On the other hand, grey oil is not more efficacious than the other preparations. M. Grancher prefers friction with strong mercurial ointment, done by the patient himself during 20 minutes daily for three weeks.

During the secondary period of the malady, the mercurial treatment should be less intensive, with periods of rest. During the second year the treatment should be prescribed one month out of two, the third year one out of three, and the fourth year one out of six months.

In ordinary average cases of syphilis the treatment should be commenced as soon as the disease is recognised. During the violent period a series of 15 injections of benzoate of mercury should be made, and the pills given at the same time. Then, if no accidents are observed, the patient should be allowed one month's rest. The gravity of syphilis depends on the subject and on the disease itself, and not on the treatment.

*Iodide of potassium* does not possess the value of mercury; it is only an adjuvant. Its indications are found where ulcerous lesions, exostosis, periostitis, or otitis exist. The dose is from 15 to 30 grains a day or more, but a drachm should not be exceeded. It should not be given in ordinary cases of the disease, as it is a drug that might become dangerous by provoking congestion or hæmorrhage, while in affections of the larynx, lungs, or kidneys its action is frequently injurious.

*Sulphur* is employed only as an eliminator of mercury.

## GERMANY.

Berlin, Sept. 5th, 1909.

THE *Deutsche Medizinische Zeitung*, No. 66, contains a notice of a paper on the

## PHAGOCYTARY ACTIVITY OF THE RED BLOOD CORPUSCLES,

by Dr. Sewastianoff, of Kiev.

Red blood corpuscles, he says, are perfect phagocytes, both *in vivo* and *in vitro*. The blood plates of Bizzozero are also phagocytes under some conditions. In all cases of natural or acquired immunity the resistance of the organism is apparently due to the biological properties of the erythrocytes. The hæmoglobin plays the leading rôle in phagocytosis. The erythrocytes are the natural carriers of the complements, the amboceptors, the fibriniferments, the antitoxines, the alexines, agglutinines, precipitines, the opsonines, antigressines, and other ferments. The bactericide and antitoxic properties of serums are dependent on the secretion of bactericide and antitoxic substances from the erythrocytes. As a weapon in the strife against microbes the erythrocyte makes use of electricity and magnetism. The question as to the disappearance of the microbes in the phagocytes is not quite solved by Metchnikoff's theory of intracellular digestion, but in the case of absolute immunity it is a factor in part, it is not the only form. The red blood corpuscle possesses independent movement, and can change its form of itself. With the erythrocytes the hæmoglobin plays the part of the nuclear substance. The red blood corpuscle possesses no covering; the latter is the product of chemical process, or of a condition unfavourable for the erythrocytes. The erythrocyte divides both *in vivo* and *in vitro* directly by budding, whereby the blood plates originate from it, and also indirectly. Electrical properties are as much characteristic of erythrocytes as they are of nerves and bacteria. Erythrocytes under certain conditions are capable of being converted into leucocytes, and in the process pass through several stages until that of the many nucleated leucocyte is reached. The pus corpuscle is undoubtedly a metamorphosed erythrocyte. There is no need for a theory of formation of leucocytes in the spleen; it is a lazarette for injured ones. Lymphocytes are polynuclear leucocytes that have undergone a change in the lymph glands; the mononuclear ones can only arise from fusion of polynuclear ones or from mononuclear erythrocytes. The expressions, leucæmia lienalis, lymphadenica, myelogenes, should no longer be made use of, as the leucocytes arise in the blood, and in the tissues, and blood-forming organs in so far as these are damaged. The notion that in every case of leucocytosis there is some irritation of the blood-forming organs, and that numerous leucocytes are then formed and collect at the wounded spot, has not yet been proved to be correct. The conversion of erythrocytes into leucocytes, and *vice versa*, forms a circle that is closed.

## RESECTION OF THE OVARY, WITH SUBSEQUENT PREGNANCY.

Dr. Zacharias reports a case of the above in the *Zentralbl. f. Gyn.*, 10/09. Resection of the ovary will naturally only be performed, he says, when the tumour which leads to the operation is of a non-malignant character, and, further, when the resection may be of some value later. In the case recorded pregnancy followed about four and a-half years after the operation. In a second case the left ovary was completely extirpated; the right was resected on account of a dermoid tumour. Menstruation ceased a year and nine months after the operation. In a third case death took place from some cardiac affection. In a fourth the left ovary was entirely removed; the right tumour, which was the larger, and which did not permit of any remains of ovarian structure to be recognised, was shelled out, so that only a very small remnant of tissue was left the thickness of a two-shilling piece; after the operation menstruation ceased entirely.

The *Monatssch. f. Augenheilk.*, June, 1909, contains an article on the

## DIFFERENTIAL DIAGNOSIS BETWEEN OCULAR HEADACHE AND THAT CAUSED BY DISEASE OF THE NASAL CAVITIES.

The writer says that 40 per cent. of the cases seeking

advice were referred to eye specialists on account of headache. In many of the cases the pain was set up by inflammatory diseases of the nasal cavities. In these diseases symptoms were present that led the patient to consult a specialist; these were photophobia, pain in the ball of the eye, accommodation pain and swelling of the eyelids, especially in the morning. In 7 per cent. of these cases he had found that the headaches were caused by empyæma of the antrum and other inflammatory diseases of the nasal passages. The following points he considers important from a diagnostic point of view:—When the pain is unilateral and distinctly localised, it points to nasal disease. All headaches that follow influenza are to be suspected; also when they are very violent and have commenced with great suddenness. Periodical headaches that begin soon after getting up in the morning, continue for some hours, and then gradually subside, disappearing entirely during the evening, are explained by accumulations of pus in the nasal sinuses when the head is low, setting up a tormenting headache; these flow away drop by drop during the day. Purulent discharges from the nose, especially when they are unilateral, often cause headaches. When the eye surgeon, therefore, finds that there is no ocular cause for the headaches, he should have the nasal organs examined by an expert in order to be quite certain that the cause of the trouble does not lurk somewhere in them.

## TREATMENT OF DIABETES.

In the *Med. Klinik*, 1905, Nos. 55/6, Dr. Manfred Fraenkel, of Berlin, presents a new theory of the pathogenesis of diabetes based on the idea that normally the transformation of glycogen into sugar is due to a ferment which arises from the decomposition of red blood corpuscles. This ferment is produced more rapidly when there are circulatory disturbances, until a point is reached when the quantity of sugar created no longer can be utilised, super-saturates the blood, and is excreted in the urine.

A condition for normal utilisation of sugar is a normally functioning vaso-motor system, with its centre on the floor of the rhomboid fossa. The trophic factors are of no small importance. A dominating position over the entire vasomotor system of the liver must be ascribed to the vagus. In this connection the relationship between diabetes and tuberculosis is of much interest. Claude Bernard found sugar-forming fibres in the lung fibres of the vagus, so that any injury to the former must also strike the latter. This explains the secondary occurrence of tuberculosis in diabetes.

Fraenkel then points out the possibility of influencing the vagus by means of eserine. He considers the activity and pathology of the pancreas and the pathology of diabetes in general, and emphasises that changes in the pancreas present themselves as interstitial degeneration, especially of Langerhan's cells. These, too, have their cause in the circulatory disturbances. In diabetes all other organs always show signs of extensive hyperæmia. The final link in his chain of reasoning is the significance of arterio-sclerosis. He cites Noorden and Croner in support of the connection between it and diabetes. Arterio-sclerosis is primarily the expression of circulatory disturbances, and, according to the location of the vascular injury, one subject is exempt from diabetes, while another succumbs thereto when the arterio-sclerosis establishes itself in the hepatic vessels.

He therefore combined eserine with the modified salts of Trunczek's serum (anti-sclerosin), the tablets being given the name of "diabeteserine," and used the same with very good results in 22 out of 29 cases.

Diabeteserine is furnished in two forms. No. 1 contains the blood salts, with 0.0004 gm. physostigmine salicylate per tablet. No. 2 contains in addition 0.0005 gm. atropine per tablet. No. 2 is ordered in cases with obstinate constipation, colicky pains, or pronounced obesity, when No. 1 fails to give the desired results. The dosage is one or two tablets thrice daily for from two to four weeks. The diet, of course, must be adapted to the requirements of the individual.

## AUSTRIA.

Vienna, 5 pt. 5th, 1909.

## INTERNATIONAL CONGRESS.

THIS week has witnessed a great exodus to Budapest, where the medical world is congregated to receive the hospitality of the Hungarian nation, where between 5,000 and 6,000 have met to discuss medical topics under the patronage of his apostolic Majesty, and represented by Archduke Joseph. The usual receptions and invitations were accorded to all the members. As might be expected, the Germans and French have sent the largest representation, while the United States and Argentine follow close in the rear. Sonnenberg, of Berlin, promoted an active discussion on the popular disease, appendicitis. He is not in favour of early operation, and declared it was not necessary in every case to operate, particularly those of a catarrhal nature, which could be treated without interference, as he had seen 300 of these acute appendicitis cured without any operation. The Vienna school have invited all the guests of the sister kingdom to visit Vienna before returning home.

## ERYSIPELAS IN THE AGED.

Schlesinger writes a long article in the *Medizinische Klinik* on the treatment of erysipelas, which he contends is induced by myodegeneration of the heart in old age. He is inclined to believe in this cause being present in the young as well, and prefers the use of digitalis to obviate this difficulty. Where bradycardia is present, he prefers caffeine and nitro-salicylic till the blood pressure falls or the arrhythmia is corrected. As a prophylactic he would rub fat into the skin after the active inflammatory condition had subsided, and where it was likely to recur. He also thinks that the affected part should be frequently bandaged to avoid the danger of hypostasis, and bathed with a 60 per cent. solution of alcohol, 10 per cent. of ichthyol or naphthalan ointment. Local applications of warmth with the thermophore often give great relief. This need not be continued for any length of time, as infiltration rapidly takes place. The suffering may often be relieved with an anæsthetic ointment such as a 10 or 20 per cent. of eucainum lacticum ointment.

## "YOGHURTMILCH."

Winkler said this was a preparation of milk prepared by a specific process, and containing three bacilli, the principal one being *Bacillus Bulgaricus*, belonging to the lactic acid bacilli group. In addition to the *Bulgaricus*, there is a *Streptococcus* and the *Bacillus lactis acidii* in the "yoghurtmilch" preparation. These microbes all flourish in acid media, and are difficult to cultivate at first, but, once established, they persist. In the stomach and bowel, when once introduced, they will be found in the alimentary canal three weeks after the administration of "yoghurtmilch." Metchnikoff is of opinion that decomposition of the bowel and its consequences can be averted by the administration of this lactic preparation, as the intestinal flora is entirely changed by its presence. Winkler assured the meeting that the Vienna "yoghurtmilch" contained the three specific microbes, and acted as a genuine intestinal disinfectant by checking the growth of the *Bacilli coli*, *proteus*, *pyocyaneus*, and thus preventing sulphur and indol product from being formed in the alimentary tract. "Yoghurtmilch" would therefore be valuable in cases of tropical dysentery, typhoid bacilli carriers, and anæmic children, due in many cases to fouling in the bowels. He further added that the milk preparation should be taken after meals, that when fresh it should have a cheesy odour, and when whey separated it was too old to be used.

Escherich remarked that "yoghurt" entirely transformed the decomposition in infants.

Sperk affirmed that it cured lichen urticatus, chronic insomnia, but thought it should not be given to children before they reached their second year.

At the International Medical Congress, at Budapest, Dr. Bashford, of London, gave a lantern demonstration illustrating the progress which had been made in cancer research during recent times. He showed that there was no foundation for the supposition that cancer was due to a microbe.

## FROM OUR SPECIAL CORRESPONDENTS AT HOME.

## SCOTLAND.

**NEW PROFESSOR OF ANATOMY IN GLASGOW.**—The King has been pleased, on the recommendation of the Secretary for Scotland, to approve of the appointment of Mr. Thomas H. Bryce, M.A., M.D., Lecturer on Anatomy in the University of Glasgow, to be Regius Professor of Anatomy in that University, in succession to Professor Cleland, resigned. Dr. Bryce has been looked on as Dr. Cleland's probable successor ever since the resignation of the latter was announced. He enjoys a high reputation, particularly in the domain of embryology, in which he has done brilliant work. He is the editor of the new edition of "Quain's Anatomy," and has also published several papers dealing with archæological topics. Since 1892 he has lectured on Anatomy at Queen Margaret College, Glasgow. Dr. Bryce is a cousin of the British Ambassador to the United States.

**NEW PROFESSOR OF SURGERY IN ABERDEEN.**—The appointment by the Crown of a successor to Professor Ogston, Aberdeen, is also announced. Professor Marnoch, the new professor, is a native of Aberdeen, and is 42 years of age. He has held various surgical posts in the Aberdeen Infirmary and in the Children's Hospital there, and was at one time on the staff of the Aberdeen Eye Institution. In 1892 Dr. Marnoch began to specialise in surgery, and at the same time, while assisting Professor Hamilton, carried out some researches on the ætiology of cancer the results of which, published in 1901, attracted considerable attention at home and abroad. In 1900 Dr. Marnoch was appointed Surgeon and Lecturer on Clinical Surgery to the Infirmary, and since then has devoted himself exclusively to consulting and operative work.

## LIVERPOOL.

**DEATHS UNDER ANÆSTHETICS.**—The *Liverpool Courier* of the 3rd inst. reports an inquest that was held on the 2nd on the body of a man who had met with an accident the day before which necessitated, in the opinion of the medical man he consulted, an operation for the removal of bone. The man demurred to taking chloroform, but afterwards consented, and, while the anæsthetic was being administered, he collapsed and died. Artificial respiration had been resorted to, but without effect. At the inquest on the following day, Dr. Owen is reported to have stated that the man's organs were in a very bad state. Death was due to syncope, probably due to weakness following the shock of the injury. There is no evidence in the report of the inquest that any other medical man was present when the chloroform was administered than the one who was to perform the operation. Now it has often been emphasised, and it cannot be too often repeated, that when a case is important enough for the administration of an anæsthetic it is important enough for the attendance of a second medical man. No one should undertake to give an anæsthetic without some professional assistance. There is also a second point that deserves to be mentioned, and it is this concerning the preliminary administration of a stimulant whenever chloroform has to be given. A well-known physician, a staunch abstainer and public temperance advocate, will never allow one of his patients to have chloroform administered without a preliminary dose of half-an-ounce to an ounce of some alcoholic stimulant. It would be well if this rule were universally followed. If this preliminary dose of alcohol is advisable in ordinary cases, it is certainly much more urgently called for when the patient is suffering from the shock of a painful accident, and when the action of the heart is more than usually feeble. Possibly the stimulant was given in the case reported, but no mention was made of it in the published account.

WE regret to announce the death of Mrs. Lawson Tait, the widow of the famous Birmingham surgeon, which took place on August 27th at Exmouth.

## LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

### WASSERMAN'S FIXATION TEST FOR SYPHILIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Helme's admirable paper in this week's number of your journal throws a great deal of light on Wassermann's fixation test for syphilis, but it should be remarked that this apparently complicated reaction has recently undergone considerable simplification.

In the *Lancet* of May 29th of this year, Dr. Fleming, writing from Sir A. Wright's laboratory at St. Mary's Hospital, describes "A Simple Method of Serum Diagnosis of Syphilis."

Instead of the guinea-pig serum sensitised to rabbit's blood required in Dr. Helme's description, Dr. Fleming, like Heslet, finds the necessary amboceptor, as well as a hæmolytic complement in the serum proposed to be tested.

The new method also dispenses with the portion of "liver rich in treponemes"; as Dr. Fleming's paper shows, an alcoholic extract of heart muscle acts just as well.

Dr. Fleming's results, I might add, have recently been contested (*Brit. Med. Journ.*, p. 377), but Dr. Clemenger, working in the same laboratory, has shown (*Brit. Med. Journ.*, p. 575) that these objections were quite unjustified.

I am, Sir, yours truly,

A. W. GILCHRIST, M.D.

Nice, September 3rd, 1909.

### TEMPERATURE-TAKING IN THE MOUTH.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Is it necessary? I am glad to see attention called to this habit in your columns, page 186, August 25th, 1909, and that it has also been alluded to in the *Times*.

Personally, I regard the habit from a sentimental point of view as not a nice one under any circumstances, and repulsive if thorough cleansing is not observed. One marvels that three eminent medical men should have overlooked the claims for cleanliness in such a matter.

There is some difference between the temperature taken in the mouth and that taken in the axilla, but I do not believe that the difference is such as to vitiate the conclusions drawn from a practical point of view. There is another side to the question. In taking the temperature in the mouth, you shut it, and so waste some minutes which might usefully be employed in asking necessary questions and so shortening the duration of the visit to that extent.

I am, Sir, yours truly,

ONE WHO KNOWS THE VALUE OF TIME.

August 25th, 1909.

### THE DECLINING BIRTH-RATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—My aim was not to carry on a barren controversy, and I am afraid that, although I may, by your favour, publish further letters on this subject, I cannot reply to any more of Mr. Clement Sers' communications. His fundamental statements are not correct, and I am too dense to be able to follow his reasoning. It is not correct to state that the prosperity of Germany is due to the fact that "her numerous population cultivate the soil." Nearly the whole of her increase, over 25,000,000, since 1871, has gone to swell the population of the towns, and to carry on the industries which have been created during those years, and have converted Germany from an almost purely agricultural country into the greatest manufacturing people on the continent of Europe. The same change has not taken place in France. Her rural population maintains its relative proportions; her fertile soil could sustain many more millions than at present subsist upon it;

and her numbers, 38,000,000, have been barely kept up by immigration from Switzerland, Italy, and Germany. She has vast "colonies," and no people to send to them. She has lost her dominant position in Europe, and, without allies, would lie at the mercy of Germany. Other things being equal, the big battalions in a fight to a finish command victory, and Germany can call into the field almost twice as many men as France. Human nature in France is sufficiently like that in England to justify conclusions with regard to our own people from the phenomena observable there. Sociology is not an exact science, but evolutionary changes involving similar elements and forces are followed by similar reactions. M. Bertillon—an authority whom everyone will respect—has within the last few weeks declared that "France is marching rapidly to her ruin." He bases his statement on the population statistics. He shows that the lowest birth-rate prevails among the classes, who fully appreciate the injury their customs are inflicting upon the "*Patrie*" to which they are never tired of proclaiming their devotion. In 445 families of the intellectual *élite* he found only 575 children. The parents of such families are all able to rear and put out in the world a normal number of children. They refuse, and for purely narrow, selfish reasons. Then I may cite M. Paul Leroy-Beaulieu, a name which will be recognised as authoritative. He contributes an article occupying more than a column to the *Standard* of August 24th. He shows that without some compensation by immigration from abroad, depopulation in France would be absolute and continuous. He proves that marriages are as frequent in France as in other countries; that the low birth-rate is essentially voluntary; that a proportion of married couples do not care to bring children into the world; that a preponderating majority do not wish for a family of more than one child (at the maximum two); and that few have three children or more. He ascribes the motives to the selfish origins I have spoken of, and dwells upon their intensely anti-patriotic character. Among the causes of this moral decline he enumerates a taste for luxury and the decay of religion—the tendency of State education having been for twenty years systematically opposed to religion. The people have all come to believe that in bringing up two or three children they are making too great a sacrifice. M. Leroy-Beaulieu then enters into a lengthy description of a scheme for the endowment of large families, necessary, as he holds, in view of "the grave threat which is beclouding the future of France." This would cost many millions annually, but, "in contrast with so much wasteful expenditure of to-day, this would, at least, have the merit of being useful." My letter is already too long. To discuss the question fully would need a volume. I may with your permission return to it on another occasion.

I am, Sir, yours truly,

A STUDENT OF SOCIOLOGY.

September 2nd, 1909.

## OBITUARY.

BENJAMIN GRAY HEALD, L.R.C.S., L.F.P.S.  
GLASG., J.P.

AFTER an illness extending over several months, Dr. Benjamin Gray Heald, surgeon, died at his residence in East Leeds, in his sixty-third year. A son of the late Samuel Linley Heald, a well-known Leeds surgeon of a former generation, he followed in his father's professional footsteps. Immediately after qualifying, he commenced practice in Leeds, settling in the East Street district.

It was in 1889 that Dr. Heald made his *début* in the City Council, being elected as a Liberal in that year to fill a casual vacancy in the representation of the East Ward. He sat continuously for fourteen years, surviving three contested elections, and enjoying two unopposed returns. He filled many municipal offices, and was made Justice of the Peace in 1906.

**SIR STEPHEN MACKENZIE, F.R.C.P., M.R.C.S.**  
We regret to announce the death of a distinguished London physician and teacher in the person of Sir Stephen Mackenzie, at the residence of his son at Dorking, Surrey, on September 3rd.

This well-known physician, who was a son of Mr. Stephen Mackenzie, of Leytonstone, and a brother of the late Sir Morell Mackenzie, was born in 1844. He received his education at Christ's Hospital, and medically at the London Hospital and at the Universities of Aberdeen and Berlin. He took his M.B. degree (highest honours and special honours for his graduate's thesis) at Aberdeen in 1873, and his M.D. degree two years later. He became M.R.C.S. of England in 1869, and a member of the Royal College of Physicians in 1874, and a Fellow of the latter College in 1879. Amongst other posts he was Consulting Physician to the London Hospital, the Poplar Hospital, and the Royal Ophthalmic Hospital, and an ex-President of the Metropolitan Counties Branch of the British Medical Association. He was formerly Lecturer on Medicine and Pathology at the London Hospital Medical College, and he carried on an extensive private practice. His publications include numerous articles in medical dictionaries and periodicals.

Sir Stephen Mackenzie married, in 1879, Helen, the youngest daughter of Mr. Benjamin Dulley, of Wellingborough, and had three sons and one daughter. He was created a knight in 1903.

## MILITARY & NAVAL MEDICAL NOTES.

**INDIAN MEDICAL SERVICE FAMILY PENSIONS.**—The Government of India has been pleased to decide that officers of the Indian Medical Service who subscribe to the Indian Military Service Family Pensions should in future do so under the same conditions as officers of the Indian Army—i.e., their classification should be regulated according to length of service, instead of, according to rank, as follows:—Surgeon-Generals should be allowed to subscribe in Class I., as hitherto; Class II., officers of 20 years' service; Class III., officers of 12 years' service; Class IV., officers of 6 years' service; Class V., officers of less than 6 years' service. No existing subscriber should be reduced to a lower class than that in which he now subscribes. The orders will have effect from May 16th, 1909.

**MEDICAL SERVICE.—TERRITORIAL TRAINING.**—The *Times* military correspondent, reporting on the auxiliary services of the Territorials, says that he has not had time to examine these in detail, but promises to do so later on. He says, however, that from things seen and from the opinions of qualified authorities, these services have done very well. As to the medical service, it is spoken of as "very efficient"; its *personnel*, officers, and men decidedly good, and every opportunity taken to exercise it. The promised later report in detail will be interesting and instructive. As everything is now done to render the medical branches of both Regulars and Territorials efficient, we anticipate a favourable judgment.

**MILITARY NURSES.**—Head nurses employed in military families' hospitals other than Aldershot are to receive pay at the rate of £55 per annum, increasing by £2 yearly to a maximum of £65. Assistant nurses are to receive £35 per annum, increasing by £2 annually to a maximum of £45.

**IMPROVED HEALTH IN THE ARMY.**—Lord Kitchener's circular letter, issued in Simla this month, draws attention to the great improvement in the general health of the British and Indian troops. The death-rate of the former has fallen from 17.13 per 1,000 between the years 1894 and 1903 to 9 per 1,000 in 1908, and the constantly sick in hospital from 5,384 to 3,139,

which means an addition of 2,000 to the fighting line and a saving of 500 lives yearly. Enteric formerly averaged 1,476 attacks and 380 deaths yearly; now there are 998 cases, with 188 deaths. Dysentery has been reduced to one-half, malaria to two-thirds, and venereal diseases to one-fifth, and the men invalided from 2,123 to 905. The death-rate of the Indian Army has been reduced from 11.33 per 1,000 to 7.41, and the constantly sick from 3,721 to 2,749.

**R.A.M.C. INSTRUCTION.**—A camp of instruction for the Royal Army Medical Corps has been opened at Bulford, on Salisbury Plain, for the training of detachments of the corps in field hospital duties. The camp will remain till September 25th.

**FRENCH FIELD HOSPITALS.**—Considerable improvement has recently been made in field medical organisation of the French Army. Uniformity has been obtained by the provision of ambulances equipped and organised in the same way, and the variety which has existed up to the present in both ambulances and in the field hospitals has disappeared. The new system, the *Military Mail* reports, resembles that of our own Army, having, among other branches, a stretcher-bearer section and a sanitary section for hygienic investigation, disinfection, and similar duties.

**MILITARY SANITATION.**—With this title a most important and portable book has just been brought out by Major R. J. Blackham, R.A.M.C., D.P.H., Sanitary Officer to one of the divisions of the Indian Army, with headquarters at Cherat, near Peshawar. Major Blackham has spared no pains to bring all that bears on the health of the soldier into a reasonable compass, and is to be congratulated on having achieved this object. No Army Medical officer's portable library should be without this work. Space does not permit of going into a notice of the chapters on air, water, food, clothing, housing, disinfection, communicable diseases, camp and march, venereal disease, etc., etc., which are all well handled.

## REVIEWS OF BOOKS.

### THE MATHEMATICS OF HYGIENE. (a)

THE popularity of this little book is attested by the fact that a fourth edition has been quickly called for. The subject-matter dealt with usually presents great difficulty to the average candidate for a public health diploma. Medical men, as a rule, know little regarding the intricacies of mathematical calculations; in fact, the writer of this useful guide—for such it is—takes for granted that his readers know little or nothing about the methods of chemical and physical calculations. As a consequence, he supplies the knowledge lacking in an extremely elementary and readily understood form. The best recommendation we can give this book is to state that we have personally known candidates who, when they started to study it, knew practically nothing about mathematical methods, but who, when they had finished, were able to give an intelligible account of the subject.

The subjects dealt with, include, amongst others, the laws of gases, hygrometry, hydrostatics, heat, ventilation, rainfall, and sewerage, while logarithms, the bugbear of students, receive very special attention. The present edition contains some thirty odd pages more than the last, while the text is arranged in a much more consecutive manner than before. Thus the various matters which were treated of in an appendix have now been placed in the text, which makes the study of the book much simpler. Several new examples, mostly culled from recent examination papers, have been added. A special feature of this edition is the new chapter dealing with the construction of life-

(a) "Aids to the Mathematics of Hygiene." By R. Bruce Ferguson, M.A., M.D., B.C.Cantab., D.P.H. Eng., etc. Fourth Edition. Pp. x., 182. London: Baillière, Tindall and Cox. 1909. Price: cloth, 2s. 6d. net.

tables. This, we consider, is a most valuable addition, and one which practitioners and students are sure to appreciate. The method adopted in the preparation of life-tables is somewhat complicated, but the author has done everything, humanly speaking, to make it as easy as possible for the public health student.

Taking the book as a whole, we may safely express the opinion that it is the very best that candidates for public health diplomas can use; in fact, there is none other which covers the same ground. It really supplies all the information required on this particular subject, and it is therefore only a waste of time to study larger works, which too often only serve to confuse rather than to aid the student. We trust this fourth edition will meet with as hearty a reception as its predecessors. It certainly deserves it, and the author is to be congratulated on the success of such a compact, accurate, and at the same time eminently helpful volume. It well sustains the high reputation of the excellent "Aids Series" in which it appears.

#### ABDOMINAL HYSTERECTOMY. (a)

THIS small volume contains essays on the title subject and five others, all of which afford interesting reading, and coming from so well known a pen as that of Mr. Bland-Sutton, are sure to be read with interest. The statistics for abdominal hysterectomy in eight London hospitals in 1896 are compared with those of 1906, and show the great advance made in that decade by this operation, the mortality falling from 22.5 to less than 2 per cent. The author puts in a plea for the use of rubber gloves by all connected with the performance of hysterectomy, as this practice not only reduces the mortality, but the unpleasant sequelæ also, especially trouble with the ligatures and sutures. His experience supports the view that fibroids produce changes in the endometrium, inflammatory, etc., which tend to induce cancer, and that in patients over 50 years of age operated upon for fibroids 10 per cent. have cancer—his own experience was 8 cancers out of 63 cases—therefore this must be looked for immediately at operation, and if found or suspected the cervix must be removed. With regard to cancer developing in the cervix left after sub-total hysterectomy, its occurrence is divided into four classes:—1, existing at time of operation and overlooked; 2, developing subsequently; 3, the original growth was malignant, sarcoma; 4, the new growth is a granuloma. Dealing with sarcoma, he considers the most insidious danger is the occurrence of encapsuled sarcoma in the guise of an innocent fibroid. He records a case (p. 9) to illustrate this, and is sceptical about the degeneration of fibroids into sarcoma. He has a decided preference for sub-total hysterectomy, especially in spinsters and barren women, and is strongly in favour of retaining one ovary if healthy, as it modifies and postpones the symptoms of the menopause, but these occur in a few years from atrophy of the retained ovary, the period of time depending on the age of the patient at the time of operation. He deals very fully with injuries to the ureters in the third essay. The most dangerous occur in connection with sub-total hysterectomy, as they are most often overlooked: the method of treatment depends on the time the condition is recognised, and is divided into primary and secondary, varying from suturing of the ureter and implantation into the bladder to excision of the kidney. The method of Lutaud for implantation into the bladder is described in detail. In the fifth essay on thrombosis and embolism, he refers to the coagulation due to the extension of cancer cells into a blood vessel, and points out that although the view is held that cancer cells promote thrombosis, he considers that this is due to infection of the tumour and the influence on the blood by the micro-organisms and their toxins. Post-operative thrombosis is divided into three groups:—1, the involvement of the saphenous veins usually due to infection from the abdominal incision

by route of the superficial epigastric veins; 2, of the femoral and iliac veins, the infection proceeding from the vessels about the stump, especially the uterine veins; 3, of the ovarian veins, as a sequence to uterine sepsis. The author considers that ligation of the veins holds out hope of success in treatment in chronic cases of infective thrombosis, but that in acute cases it is unsuitable, and that there is need of further experience to teach the kind of puerperal pyæmic cases in which it is likely to be successful. Pulmonary embolism is also dealt with, and it is shown how a small embolus may be sufficient to cause blocking of the pulmonary artery. The last essay is on adenomyoma of the uterus and tuberculosis of the endometrium.

#### HYGIENE IN THE TROPICS. (a)

EVEN among the most civilised of Western nations the knowledge of the principles of hygiene is far in advance of the practical application of them. There are, we believe, two main reasons for this state of things, the influence of both of which will diminish with the progress of civilisation. First, there is the apathy of the public due in a large measure to ignorance, but also to a spirit of conservatism, which one so often hears expressed when progress means expenditure for the attainment of an end apparently only indirectly advantageous. The second cause which has retarded progress is the inherent difficulty of the application of general principles to actual practice. Such application must at first be tentative and experimental, yet the experiments must often be made on such a large scale, and involve so much expense, that one does not wonder that public bodies hesitate to undertake them. The knowledge of how best to adapt general principles to local conditions can only be learned by experience, and experience must often be bought by failure. Too often, we fear, the inability to recognise the necessity for this adaptation has been the cause of failure, and sanitarians themselves have brought discredit on their cult by a too strict adherence to what they believed were immutable principles. In tropical climates the difficulties of the sanitarian are enormously increased, and not only so, but the penalties for failure are much more severe. Indeed, the very existence of a civilised community in tropical climates is dependent on the success of the sanitary administration. Dr. Simpson has done good service in the book before us, not only in elucidating principles, but also in showing how those principles are to be applied under the very varying circumstances of tropical and sub-tropical administration.

#### NEURASTHENIA. (b)

THE fact that Dr. Ballet's book has already reached a third edition in the original French is in itself a justification for the issue of it in the English language. The teaching of Dr. Ballet is so well known that it is unnecessary to enter into an elaborate criticism of it. We are not inclined to accept Dr. Ballet's conception of neurasthenia as a definite "somatic disease of the nervous system," and would rather consider it as a symptom of many different physical disabilities, the recognition of which, with our present knowledge, is always difficult and sometimes impossible. Until our knowledge has very greatly increased, the term "a neurasthenic" will have a large denotation, and while it has, those whom it denotes must be treated on principles such as are laid down by our author. To those interested in the treatment of such patients, we can recommend Dr. Ballet's book, and those who wish to read it in English may with every confidence turn to Dr. Smith's translation.

(a) "Essays on the Position of Abdominal Hysterectomy in London," By John Bland-Sutton, F.R.C.S. Eng., Senior Surgeon, Chelsea Hospital for Women, Surgeon to the Middlesex Hospital. With thirteen illustrations. London: James Nisbitt and Co. 1909.

(a) "The Principles of Hygiene as applied to Tropical and Sub-Tropical Climates, and the Principles of Personal Hygiene in them as applied to Europeans." By W. J. R. Simpson, M.D., F.R.C.P. Octavo, pp. xii. and 396. Illustrated. London: John Bale, Sons and Danielsson, Ltd. 1908.

(b) "Neurasthenia." By Gilbert Ballet. Translated from the Third French Edition by P. Campbell Smith. Octavo, pp. xxviii. and 408. London: Henry Kimpton. 1908.

## NOTICES TO CORRESPONDENTS, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

### SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

### ADVERTISEMENTS.

For ONE INSERTION:—Whole Page, 25; Half Page, 23 10s.; Quarter Page, 21 5s.; One-eighth, 12s. 6d. The following reductions are made for a series:—Whole Page, 13 insertions, at 23 10s.; 26 at 23 3s.; 53 insertions at 23, and pro rata for smaller spaces. Small announcements of Practices, Assistances, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

### NOTICE TO HOSPITALS AND COLLEGE DEANS.

THE Editor desires to thank the above gentlemen attached to the various Schools and Hospitals for supplying him with the information from which the foregoing pages have been composed.

### NOTICE TO OUR READERS.

As this number is mainly devoted to information necessary for students intending to join one or other of the various medical colleges, and for those who, having passed their curriculum, are about to enter the ranks of the profession, much of the ordinary matter which usually fills our columns is necessarily deferred till next week.

### GRATUITOUS COPIES

A VERY large number of copies of this issue are being sent gratuitously to all the educational establishments, hospitals, reading-rooms, clubs, and large hotels in the United Kingdom, and to a large number in America, India, the Colonies, and on the Continent. Should any of our readers desire to present a copy to a patient or friend who contemplates sending his son to a medical school, our publisher will be happy to supply him with a duplicate free of cost on receipt of address.

### A ROCKEFELLER STORY.

Of the many stories that are in circulation about Mr. Rockefeller there is one which is not only absolutely authentic, but which throws a curious light upon the character of the famous millionaire. Many years ago Mr. Rockefeller was a clerk in a Chicago house, at a salary of two pounds a week. He had an ailment which required a simple and harmless operation. He went to a surgeon of high repute in Cleveland, and arranged to pay so much a month. Not long ago the old complaint manifested itself again, and Mr. Rockefeller sent for the doctor of his youth. When the examination was over, he remarked, "I won't keep you waiting for your money this time. Things have changed with me." "Oh," said the other, "I am out of practice; I wish no fee." Mr. Rockefeller stepped to his desk, placed bills to the amount of £250 in an envelope, and handed them over to the surgeon with the remark, "Well, if you don't want to take a fee, perhaps you will kindly give these to some poor young doctor of your acquaintance."—*M.A.P.*

F. S. TOMLINSON (Kent).—Yes; much might be done by the appointment of a conscientious and capable health visitor. In a poor district an immense amount of good may be effected by a tactful official of that kind in the course of a house to house visitation. To mention a few elementary points, the gospel of the open window and of the open chimney may be taught, the cleansing of houses, and the tending and feeding of infants. It is of course essential that a suitable visitor be chosen, and that she should work loyally under the Medical Officer of Health.

### THE LAW OF EVIDENCE.

A correspondent asks if he is compelled by law to give evidence, confidentially obtained, in a case in which he is summoned as a witness, or whether he can legally refuse to answer when questioned? We are afraid that in law a medical man has no privilege to avoid disclosing evidence. Of course he is not expected to act as a detective, nor to go out of his way to gain evidence. On the other hand he should not withhold information likely to shield crime.

OMI PROFANUM VULGUS.—The place you mention is known to us, and although picturesque and restful, we fear it cannot be

recommended as a residence for any visitor in search of health. Sanitation is imperfect, consisting of earth closets and cesspools. There is no proper water supply, and water for domestic purposes is obtained from shallow surface wells, the water of which is liable to constant contamination by slop water habitually thrown upon a sandy and pebbly soil. How such a condition of affairs is tolerated in a so-called health resort is a profound mystery.

## Vacancies.

Stirling District Asylum.—Assistant Medical Officer. Salary £125, with board, etc. Applications to the Medical Superintendent. City Fever Hospital, Little Bromwich, Birmingham. Resident Assistant Medical Officer. Salary £120 per annum, with board, lodging, washing, etc. Applications to the Medical Superintendent. The Royal Portsmouth Hospital, Portsmouth. Senior House Surgeon. Salary £100 per annum, with board, residence, laundry, etc. Applications to B. Wagstaff, Secretary. British Ophthalmic Hospital at Jerusalem.—Assistant Surgeon. Salary £300 per annum, with house. Applications to the Honorary Secretary, British Ophthalmic Hospital, St. John's Gate, Clerkenwell, London, E.C. Bradford Poor Law Union.—Assistant Resident Medical Officer. Salary £130 per annum, with rations, apartments, and laundry. Applications to George M. Crowther, Clerk to the Guardians, Union Offices, Manor Row, Bradford. Newcastle-on-Tyne Dispensary.—Visiting Medical Assistant. Salary £160 per annum. Applications to the Hon. Secretary, Joseph Carr, Chartered Accountant, 26 Mosley Street, Newcastle-on-Tyne. Southwark Union, London.—Assistant Medical Officer at the Infirmary, East Dulwich Grove, S.E. Salary £100 per annum, with board, lodging, and washing. Applications to Sydney Wood, Clerk, Union Offices, John Street West, Blackfriars, S.E. Great Yarmouth Hospital.—House Surgeon. Salary £100 per annum, with board, lodging, and washing. Applications to Richard F. E. Ferrier, Hon. Secretary, 33 Hall Plain, Great Yarmouth. York Dispensary.—Resident Medical Officer. Salary £130 a year, with board, lodging, and attendance. Applications to Dr. Swanson, The Pleasaunce, Heworth, York. Sussex County Hospital, Brighton.—House Surgeon. Salary £120 with board and residence in the Hospital with washing. Applications to the Secretary. Fermanagh County Asylum.—House Surgeon (Anesthetics). Salary £72 per annum. Applications to C. Wilson, Secretary. (See Advt.).

## Appointments.

COWPER, C. M. L., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Act for the Arnesby District of the county of Leicester. CROWLEY, RALPH HENRY, M.D., M.R.C.P.Lond., Assistant Medical Officer to the Board of Education. GRAHAM, H. L., M.B., B.S.Lond., Assistant Medical Officer of the London Open-air Sanatorium, Wokingham. JARVIS, JOHN, L.R.C.P.Lond., M.R.C.S.Eng., District Medical Officer by the Bath Board of Guardians. LAWRY, RICHARD COGER, L.R.C.P.Lond., M.R.C.S.Eng., Medical Officer to the Penzance Education Committee. McDONALD, JAMES, M.B., M.S.Edin., Certifying Surgeon under the Factory and Workshop Act for the Belford District of the county of Northumberland. SCRUBY, Miss Z. M., M.B., B.S.Lond., School Medical Officer to the Isle of Ely County Council. THOMSON, ERIC A., M.B., Ch.B.St.And., Medical Officer to Dundee Poorhouse. WATSON, HENRY ELLIOTT, M.B., Ch.B.St.And., Resident Medical Officer in King's Cross Fever Hospital, Dundee. WELCH, CHARLES HERBERT, L.R.C.P.Lond., M.R.C.S.Eng., District Medical Officer by the Bath Board of Guardians.

## Marriages.

HARRIS-THOMSON.—On September 2nd, at the Parish Church, Stroud, Herbert Elwin Harris, B.A., M.B., Cantab., F.R.C.S.Eng., Clifton, Bristol, to Nellie De Winton, second daughter of Major-General David Thomson, R.E., Cheltenham. HUGHES-RAY.—On September 1st, at St. Anne's Church, Kew, Ernest Cranmer Hughes, M.C., F.R.C.S., son of Dr. and Mrs. Hughes, of Plymouth, to Constance Ellen, daughter of the late Humphrey Hinton Ray and Mrs. Ray, of Kew.

## Deaths.

BERNAYS.—On August 30th, at Shirley, Warwickshire, suddenly, Sarah Jane (Saar), widow of the late Herbert Leopold Bernays, M.R.C.S., of Old Charlton, Kent, aged 63. HULME.—On August 27th, at Malta, T. Haylock Hulme, M.B. Durham, L.D.S., R.C.S.Eng., aged 33. MACKENZIE.—On September 3rd, at Rose Hill, Dorking, in his 65th year, Sir Stephen Mackenzie, M.D., F.R.C.P., late of Cavendish Square, and for many years Senior Physician to the London Hospital.

## NOTES AND COMMENTS.

**The New Hall of the London Royal Colleges.** THOSE to whom the examination hall on the Victoria Embankment of the Royal College of Surgeons of England and the Royal College of Physicians of London are familiar will probably hear with some regret that the hall has been sold and that a new one is to be built in Queen Square, Bloomsbury, W.C. The new site will probably be of less value than the old, so that the Colleges should acquire a handsome sum as the result of the change. At the same time it is to be regretted that such old and wealthy corporations should not have retained so fine a building on so fine a site as that upon the Embankment. The combination of the Royal College of Surgeons of England with that of the Physicians of London emphasises the conservatism of the latter body. The Medical Act of 1858 plainly contemplated the Physicians changing their title to that of England, "by means of a new charter for which due powers were given." Possibly, however, a new charter would have necessitated other innovations, such as an examination for the diploma of fellow, so as to bring the Physicians more into line with the Surgeons. At present we have the anomaly of a fellowship given by the one only after rigorous examination, but by the other as a simple courtesy distinction bestowed upon a limited number of members. It is only on the lower planes that the Colleges meet, and even then their respective planes differ by the gulf that lies between the member and the licentiate.

**Dutch Oysters and Infection.** THE oyster trade, both at home and abroad, seems destined to receive periodical shocks, and there is every likelihood of the continuance of the adversity until the whole trade, from sea-bed to customer's table, is stringently guarded from any possibility of contamination. The Dutch government, alive to the influence of cholera scares upon this particular industry, have written to the London Fishmongers' Company through their Superintendent of Fisheries to the effect that, "Oysters with certificates are absolutely free from possible choleraic infection. I have taken all measures of precaution." How, we may ask, is the consumer to know that any given oysters have been sold under guarantee? Years ago, THE MEDICAL PRESS AND CIRCULAR suggested that the only way out of the wood was to stamp each individual shell with a mark identifying place of origin and date, according to a plan that was, we believe, protected at the time by a medical man. Meanwhile, the oyster trade has languished steadily, although there are probably enough admirers of the oyster to bring back a fair amount of prosperity were means taken to guarantee the purity of all

oysters sold by an indelible mark, or token affixed to the shell. We commend the idea, even at this late hour, to the commonsense of the Fishmongers' Company.

**Short Hair for School-girls.** THE close-cropped head of hair has long been recognised as the best of fashions for the school-boy, who, as a rule, favours that particular plan for the rest of his days. Short hair, however, is the exception in the case of school-girls, who at that early age appear to be, as a rule, fully conscious of the attractiveness of that peculiar product of evolution. Nor is it likely that mothers generally will consent to send their girls to school shorn of their long locks. A medical officer of health recently issued a circular to the parents in his district asking them to get their girls' hair cut short, and adding his opinion that some day long hair in school-girls will come to be recognised "as a badge of uncleanness." This action appears to have been resented by the parents; at any rate, it is announced that after the holidays the children returned to school without a single response to the official appeal. For all that, we think the medical view was correct, and that for various reasons the practice of cropping the heads of school-girls is to be advocated, not only in the case of children attending public schools, but in all ranks of society. Fashion, however, is not likely to be readily moved to listen to the voice of reason in a matter of this sort.

**Parsimonious Salford Guardians.** THE need of a vigorous central Poor-law administration is, from time to time, made apparent by the newspaper chronicles of parsimony that hail at uncertain intervals from various parts of the kingdom. One of the latest eccentricities of the kind is reported from wealthy Salford, a brief note of which will be found in our news column. The Guardians, on the retirement of the present senior resident medical officer, have determined to cut down the salary by £70, and at the same time to reduce his status. Their action has been taken in face of the opinion of Dr. McVail, in the Report of the Royal Commission, that their institution, with its 500 patients, was understaffed. A Local Government Board inspector has since emphasised that position. It now remains to be seen what the Central Board will do now that the Guardians have wantonly filled up the cup. It would be difficult to imagine a case in which strong central administrative control could be more urgently needed. The medical profession, it is encouraging to note, have not remained quite passive under this mean and miserly encroachment—that is to say, if there be any truth in the general surmise

that the absolute dearth of applicants for the post is due to the action of that body. The inadequate pay of many Poor-law medical appointments deserves the careful attention of the Local Government Board.

#### Yellow Fever in Barbadoes.

IN the course of a recent editorial discussion of the scientific control of tropical disease it was stated that yellow fever had virtually ceased to exist wherever scientific methods for its prevention had been persistently brought to bear. A statement by the Governor of Barbadoes since published, forcibly illustrates that remark. Prior to December, 1908, the Colony had been entirely free from yellow fever for a period of 26 years. One case was, however, reported in that month, and up to 14th June 86 cases in all were notified. Of the persons attacked 32 were white, and 54 coloured—15 of the former and 21 of the latter cases resulting fatally. No cases occurred amongst visitors to the colony, nor amongst foreign seamen. The estimated population of the colony is 194,477; the average death-rate has for years been under 11 per 1,000. In former days, certainly less than 50 years ago, such an outbreak would have probably been followed by a widespread epidemic with a very high rate of mortality.

## LEADING ARTICLES.

### THE ENDOWMENT OF MEDICAL SCIENCE.

THE necessity of the adoption of scientific methods by the State for the development of national resources is becoming more and more recognised by modern statesmen of all countries. An increasing amount of money is being spent yearly in that direction by the legislature of the United Kingdom, but the total sum thus expended represents no more than a comparatively small fraction of the national expenditure. One of the most recent examples is the grant of £20,000 to Lieutenant Shackleton, whereby the Government has formally recognised the claim of the private citizen who has risked his life and fortune in the altruistic pursuit of scientific discovery. News has just come to hand from America of the tour through Southern Russia and the less-known region of Asia of Professor Monro, of the United States Board of Agriculture. His mission is the search for new plants and grains that may be utilised for the benefit of American agriculturists. A striking illustration of the practical value of acclimatisation of the kind was afforded ten years ago by the discovery of a peculiar kind of wheat in Southern Russia, capable of flourishing in regions where the rainfall for the year did not exceed twelve or fifteen inches. But, happily, there is no need to cross the Atlantic for inspiration, for excellent work has been done at home for many years past in the ancient University of Cambridge. The special correspondent of the *Times* not long ago gave an account of some interesting and valuable practical results whereby a strain of wheat had been secured combining the superior milling and baking qualities of foreign grain, with an immunity, or, at any rate, a greatly increased resistance to "rust" and other destructive parasitic

maladies. Amongst other work done in the Cambridge laboratories is the introduction of a drug that destroys the ticks which convey various maladies to cattle, especially the so-called "red-water." If this drug proves efficient in practice, it will infallibly save the nation many millions a year. Indeed, in whatever direction we turn, we find science, in response to a liberal expenditure of time, labour and money, ready to restore the capital with a hundredfold of interest. Curiously enough, although a fair start has been made in the scientific investigation of physical and comparative science, yet comparatively little has hitherto been done by the State for the advancement of medical knowledge, although the advantage to be gained thereby in the safeguarding of the national life is infinitely greater. The cost of a single great warship would found and endow a first-rate scientific laboratory, from which the nation would be repaid a handsome interest by way of the prevention and palliation of human disease, a return that compares triumphantly with the absolutely unproductive expenditure on armaments. Some day the nation will learn to look upon science as the surest guide to the Millennium and to deduce from a selfish point of view that one of the most paying national investments is the endowment of scientific research. For some strange reason mankind appears to be in many ways more careful of the lower animals than of its own species. Take the case of the measures now being taken to control and eradicate glanders, foot and mouth disease, cattle plague and swine fever. Were a similar amount of State money and energy to be expended upon, say, human tuberculosis or diphtheria, who could doubt that the community would before the lapse of many years be more than repaid for their enterprise? There is no apparent reason why the study of human disease should not be a duty of the State any less than that of the lower animals. The recognition of the national responsibility of investigating the parasitic diseases of wheat and of cattle implies application of a similar duty to the far more valuable animal man, who has actually created the State as a means of collective protection and advancement. Of the many parasites upon the national health, it will suffice to mention the vast canker of quackery that is being permitted to eat deep into the heart of the community. Were the shameless, lying and fraudulent remedies and methods now openly advertised for the use of man to be transferred to the treatment of lower animals, it might be pretty safely predicted that Government would at once interfere and insist upon proof of the vendor's claims. In other words, the State that has recognised the necessity of a national study of the diseases of the lower animals, to say nothing of prevention and treatment, has not yet realised its responsibility as regards its own citizens. It is to be hoped that the tardy action of the General Medical Council in approaching the question of false medical practice will stimulate the Government to a juster perception of the facts of the situation. Meanwhile, it is comforting to note the magnificent, though inadequate, contributions

of private philanthropy that are from time to time bestowed upon the noble object of the scientific advancement of scientific medical research.

### THE HOUSING BILL AND MEDICAL OFFICERS OF HEALTH.

NINE well-known members of Parliament, who describe themselves as friendly to the objects of the Housing and Town Planning Bill, have issued a joint protest against what they style certain grave blots upon that measure as it now stands. With most of their criticism we have nothing to do; we are concerned only with that which refers to a question affecting the profession, the clauses of the Bill intended to improve the status of medical officers of health. By Clause 68 it is enacted that the Local Government Board is to prescribe the duties of county medical officers of health; but as these officers are appointed by County Councils and paid exclusively from county funds, the protesting members submit that it is inconsistent with local self-government for a Government Department, under such circumstances, to prescribe and vary the duties of these officers at its pleasure. Then, by the same clause, it is enacted that County Councils can dismiss their medical officers only with the leave of the Local Government Board. To this the signatories to the protest object, on the grounds that it shows a distrust of large local authorities, for which there is no excuse, and that the position of a medical officer maintained in office after having lost the confidence of his Council would be intolerable. It seems remarkable that a tendency to revert to bureaucratic methods should be manifested amidst a constant effort to democratise the whole system of government, and that the President of the Local Government Board in the present Liberal Cabinet should lay himself open deliberately to the charge of "curtailing and subordinating the powers of local self-government to the aggression of a paid bureaucracy." The fact is, however, that officers of the Local Government Board in every branch of that office are fully aware that local government is very largely a failure throughout the country; and it seems probable they have imbued the President with the same feeling. Nowhere has this practical failure of local government been more conspicuous than in the case of our rural districts, where sanitation is not infrequently of a mediæval type, and where the medical officer of health is commonly a general practitioner, ill-paid and absolutely powerless in the hands of his rural authority, composed of members who are eager to defend their private and purely selfish interests. The future of rural sanitation depends to a great extent on the institution throughout the country of county medical officers, well-paid, specially qualified and independent of the local authorities. County councillors are the *élite* of urban governing bodies, and if they cannot be trusted to engage competent medical officers, and to maintain the best possible relations with them in every respect, what can be expected from smaller urban and rural authorities, which are mostly filled by men of inferior value in every respect? The chief remedy for the present state of things lies in improving the quality of local

governing bodies, from county councils downwards; and this can be done only by rousing the spirit of patriotism, and especially of local patriotism, and by thus getting what is best among the citizens in real personal worth and intellect fully represented upon all local governing bodies. A truly appalling amount of apathy is at present displayed everywhere in this direction, and unless it can be overcome great part of the enormous mass of new social legislation must remain inoperative. There is further the danger of corruption, which, even the worst examples of local administration were formerly not thought capable of, but which has been latterly discernible in many previously unsuspected quarters. A restricted reversion to bureaucracy, directed by a scientific and expert, central authority, may yet be witnessed in many departments of our social administration. Such methods have produced, and are still producing, enviable results throughout the German empire, and are furnishing an example which may one day well prove irresistible in our own country. Meanwhile, it may be hoped sincerely in the interests of the nation that Mr. John Burns' tenure of office may be distinguished by the nominal creation of the County Medical Officership of Health.

### CURRENT TOPICS.

#### The Opsonic Index and Vaccine Therapy and Immunisation.

ST MARY'S HOSPITAL, and the Mount Vernon Hospital are each making appeals for funds for their special departments of vaccine therapy and immunisation. The department in St. Mary's is under the direction of Sir Almroth Wright, F.R.S., that of Mount Vernon under Dr. R. W. Allen. The preparation of vaccines is a laboratory work requiring both much time and the highest attainable degree of skill and care; and, as every medical reader is aware, the administration of the vaccines has still to be guided constantly by frequent microscopical examination of the blood, which at present can be conducted only by experts. The money is wanted for the maintenance of the necessary laboratories, and laboratory workers, as well as for the support of wards in which treatment can be conducted under conditions most favourable for scientific observation. The results that have so far been achieved are so far promising; and given the means to pursue his researches and experiments, there need be no doubt he will be able to bring the treatment in due course within the scope of all ordinary medical practice. The prevention of disease vitally concerns the general public, and when funds are needed such as are now asked for they ought surely to be forthcoming. Although medical men ought not to be taxed in order to help in prevention of disease, the source of their income, we do not doubt that they will, as usual, contribute towards the funds. A great part of medical research work has always been paid for out of the pockets of doctors; whilst those who devote their lives to the pecuniarily unprofitable work of pure science, never receive from the State or the public any adequate return for their sacrifices on behalf of humanity.

As regards the opsonic index and accompanying methods they have now been before the profession for several years, and it is to be regretted that no simplification has been introduced in order to bring their benefits within the reach of the general practitioner and within the means of the general public.

#### Russia and the Cholera.

The Nemesis that sooner or later overtakes the neglect of sanitation has fallen upon slothful Russia with remorseless vigour. From the latest advices—which will be found in our news column—cholera is claiming 25 victims daily in St. Petersburg alone, while 5,709 deaths from that cause have been recorded since the beginning of the year. A curious contrast is offered to the prevailing mists of ignorance and prejudice by the fact that no less than 53,182 inhabitants have submitted to preventive inoculation, and of these it is stated that twelve only have contracted the disease. Apart from that redeeming feature there could hardly be a more forcible example of the disastrous results of national neglect of the primary laws of health than that afforded by this unhappy country. Cholera, as the world learnt long ago, is a filth disease spread mainly by the agency of specifically polluted water. The water supply of St. Petersburg is hopelessly polluted and indeed plumbs therein a sanitary depth somewhat comparable with its sewage disposal. A year ago the City Fathers announced their intention of obtaining a fresh water supply and a new drainage system. They are apparently still dreaming of these far-off advantages, for their latest energies seem to have been diverted to the construction of town filters, which probably mean that they are seeking a less costly and less troublesome alternative to the only one that would be permitted by any tolerable public standard of health, namely, the institution of an absolutely new and irreproachable water supply.

#### The Government and Quack Medicine.

If the quack medicine trade were merely a question of pocket-picking and plunder it ought to be dealt with by the Legislature; the fact that, besides being to the last degree fraudulent, it involves the infliction of suffering and misery upon the simple and ignorant masses, renders the intervention of the State imperative. Medical quackery, if it can be classed only among the smaller of the evils afflicting society, is at least big enough to claim the attention of all members of Parliament who put in the first place the welfare of the people. Unfortunately, the majority of members are ignorant of the facts; but if Captain Craig will continue to keep the subject to the front there seems a fair hope that the needed enlightenment may before long be diffused. In another column will be found a report of the question put by Captain Craig in the House last week with reference to the medicine stamp duty. It is abominable that the national income should be augmented by sharing the profits of an iniquitous traffic; and it is certainly true that the purchasers of quack medicines—as Captain Craig suggested—do take the stamp to imply that the contents have the Government approval. The vast majority of the

victims of coarse quackery are ignorant, and to most of them the stamp means that the stuff they are relying upon is at least a genuine article; they cannot, at any rate, be made to believe that the Government would put its apparent sanction upon what is really a worthless, if not a harmful, imposture.

#### Basement Houses.

THE day is already dawning, we believe, in which the basement house will go to join the curfew bell, the dodo, and other relics of the past, in oblivion. A speaker at one of the recent Congresses said:—"For the ideal city there will be no houses with basements, which help to spread disease, especially tuberculosis." We cannot, however, claim for hygiene the chief word in the beneficent change which is taking place, for though its influence is all on the anti-basement side, the question has already been decided by the economic pressure of the domestic servant. This indispensable creature, thinking more of her legs than her lungs, has voted against basements, and we who are the servants of our servants are making haste to comply with her demand, and non-basement houses are springing up on every patch of suburban building land. The victory over the old type of basement tyranny is the victory of Abigail, and to her must be ascribed the credit. The unlucky owners of old-fashioned houses find more and more difficulty in letting them, and we do not withhold our sympathy from them, but from the health point of view the time has nearly arrived when a house will be considered in an insanitary condition when it can only afford domestic servants a few dark rooms below the ground level in which to spend their days and sometimes their nights.

#### "Paternal" Legislation.

THERE can be no doubt that the health and welfare of the people have been enormously improved by legislation of the kind usually styled "paternal" during the past sixty years, in spite of the fact that many laws have been found more or less impracticable, and others have been followed by injurious effects never contemplated by those who framed them. This latter fact is lucidly illustrated in a pamphlet on "Practical Eugenics," recently published by Professor Karl Pearson. Dr. Pearson expresses his opinion that the declining birth-rate is in some districts the direct result of the various Factory Acts passed during the last half century. His attention was first called to the matter by the extraordinary low birth-rate of Bradford. There, on the average, every married woman of child-bearing age has a child only once in about ten years, as against the rate of one in five years of 50 years ago. Formerly a child of six or eight years became a "pecuniary asset"; it was able to earn money and contribute towards the prosperity of the home; and by the number of the children that prosperity could usually be measured. Besides limiting the employment of children, Parliament has placed restrictions on the employment of women when near their confinement. Children thus penalise the parents, and the well-meant efforts to protect mothers and children tend towards abolition of children and motherhood.

Furthermore, in the old days parents were stimulated to take care of their children owing to their pecuniary value; they must be kept in health, because they lost their value when they broke down. Dr. Pearson thinks that, in every sense of the word, it would have paid the nation better to have devised a scheme for the endowment of parentage than to have established a system of old-age pensions, which, applied long after reproductive age, cannot possibly produce any permanent change of advantage to the race.

#### The Teaching of Therapeutics.

It is a common jest of the ungodly who scoff at the medical profession that, as a profession, we are—even as compared with other professions—hide-bound in our traditions. When one considers the place that the study of *materia medica* still takes in the medical curriculum, one is inclined to grant that there is some truth in the assertion. The subject is still taught on the same lines and with somewhat the same detail as in the days, centuries ago, when the physician gathered his herbs and prepared his galenicals. Yet, no one serious believes that it is part of the business of a medical man to know the appearance of crude drugs which he will never see, once his student days are over. Moreover, the importance given to drugs in the teaching of therapeutics is entirely exaggerated. In modern scientific medicine the place of drugs is growing less and less, and the importance of diet, of hygiene, and of vaccine therapy is increasing day by day. Yet, for all that the student usually learns in his systematic lectures on therapeutics, drugs might be the sole weapons in the armamentarium of the physician. It is difficult to over-estimate the vicious effects such teaching has on the work of the medical man and on the progress of science. We are glad, therefore, to find that among the teachers of the subject there is discontent, and particularly we welcome the paper read by Professor Dixon, of King's College, at Belfast, in which he quoted with approval Huxley's advice to abolish *materia medica* altogether from the medical course.

#### The Care of the Feeble-Minded.

THE administration of the Home Office lying mostly beyond the range and influence of party politics, it may be fairly hoped that the prospects of reform in the laws dealing with the feeble-minded are really as bright as was foreshadowed in Mr. Gladstone's reply to the deputation which waited upon him a few days ago. There prevail anomalies and deficiencies in the present system which certainly call for alteration without delay. There exist many classes of weak-minded people now outside the law who ought to be included in an amended lunacy law; whilst, as Mr. Gladstone admitted, there is urgent call for organisation and concentration of authorities in order to produce a uniform and complete system throughout the country. Then there is the question of the inebriate and the general question of criminality—the question of crime in relation to weak-mindedness. The Home Office authorities are evidently impressed with the supreme importance of the last-named subject, and Mr. Gladstone was able to promise that some steps towards reform would be taken on practical

lines. Finally, Mr. Gladstone affirmed that all were agreed that legislation was the only remedy, and pledged himself to push this forward. The Report of the Royal Commission on the care and control of the feeble-minded affords ample data and guidance for construction of new laws; the case for legislation is established; it is backed by the opinion of every responsible authority. For the sake of humanity, and for the sake of the national welfare, to which the present state of things is so hurtful, it is to be hoped that the projected new laws may soon find a place upon the Statute Book.

#### PERSONAL.

THE KING has consented to lay the foundation-stone of the extensions to the Norfolk and Norwich Hospital on October 25th. The occasion will be marked by the amalgamation of the Norfolk and Norwich Eye Hospital with the County Institution.

SIR JOHN TWEEDY, F.R.C.S., will deliver the address at the annual distribution of prizes to students at University College Hospital School on Friday, October 1st.

THE RIGHT HON. VISCOUNT RIDLEY, Chairman of Charing Cross Hospital, has consented to present the prizes at the opening of the Winter Session on October 4th to the students of the Medical School.

DR. BORDAS, Director of the Laboratories of the Ministry of France, will preside over the Second International Food Congress, to be held at Paris from October 17th to 24th.

LIEUT.-COL. DRURY, Indian Medical Service, has been appointed Principal of the Calcutta Medical College, and Lieut.-Col. Calvert, I.M.S., becomes a Professor, Calcutta Medical College, *vice* Lieut.-Col. Drury, promoted.

MAJOR T. H. M. CLARKE, C.M.S., D.S.O., Royal Army Medical Corps, serving at Plymouth, has been appointed Medical Inspector of Recruits, Southern Command, *vice* Lieut.-Col. G. G. Adams, R.A.M.C., whose period of service has expired.

ON the motion of Alderman Dr. King Kerr, Chairman of the Public Health Committee of the Dublin County Council, at a recent meeting, it was unanimously resolved to adopt Part I. of the Tuberculosis Prevention (Ireland) Act, 1908.

DR. HERINGHAM will preside at the St. Bartholomew's Hospital Old Students' Dinner, on October 1st. Tickets may be obtained of the Hon. Secretary, Mr. H. J. Waring.

DR. ARNOTT DICKSON, of Glencraig, was last week presented with a handsome gold watch and a gold fountain pen. The watch bore the following inscription:—"Presented to Dr. Arnett Dickson, in appreciation of his services, by the workmen and officials of the Glencraig Colliery and friends in Glencraig, on the occasion of his leaving the district. September, 1909."

THE number of medical men in the House of Commons has recently received an accession in the newly-elected member for West Clare, Mr. Arthur Lynch, who was described on his nomination paper as "physician and journalist." Mr. Lynch is a man of many parts—an engineer, a barrister, colonel in the Transvaal Army, journalist, author, physician. It will be remembered that he was tried for high treason a few years ago for having fought for the Boers in South Africa, and sentenced to death. The sentence was commuted, and he was released after some twelve months' imprisonment, later receiving a pardon. Since his release he has studied medicine at St. Mary's, and he recently took the Conjoint qualification.

# A CLINICAL LECTURE ON THE DIAGNOSIS OF PELVIC TUMOURS. (a)

By ARTHUR GILES, M.D., B.Sc., F.R.C.S.,

Surgeon to the Chelsea Hospital for Women; Gynaecologist to the Prince of Wales's General Hospital, Tottenham.

IN discussing the diagnosis of pelvic tumours, I shall follow the lines adopted in my monograph on "Gynaecological Diagnosis," and proceed from the known to the unknown. Thus I shall not describe to you in turn the symptoms and signs of fibroids, ovarian tumours, etc., but review the data that would be available when we are called upon to decide what is the matter with any particular patient, and note the signs and symptoms that would lead up to a diagnosis. The one feature that is common in all the cases now under consideration is the presence of a pelvic tumour, and I shall suppose that in the course of a gynaecological examination, for whatever purpose it is undertaken, some swelling is discovered in the pelvis other than the normal uterus and appendages, and the medical attendant wishes to decide what it is. The woman may have gone to him because she wishes to know why she does not have babies: there may be no symptoms, yet, on examining, he finds there is an abnormal swelling. In any case, we are taking as a starting-point the postulate that there is an abnormal swelling in the pelvis. My idea is to give you a sort of clue which you can take with you and trace out step by step what this particular swelling may be. I think the best plan will be for us to try and determine at the start whether the tumour is uterine or not. It is generally easy to tell that. Sometimes, however, it is not, and sometimes there is more than one tumour present; so that we at once get four groups of cases: I.—In the first group the tumour is evidently uterine. II.—In the second group we can be certain that the tumour is not uterine. III.—In the third group it is doubtful whether the tumour is uterine or not. IV.—In the fourth group there is more than one tumour. That at once clears the ground somewhat.

I.—We will begin with the supposition that we have determined that the tumour is uterine. We can tell that in various ways. For instance, we may be able to feel the ovaries and tubes independently of the swelling, or we may be able to satisfy ourselves there is no swelling in the pelvis corresponding to the uterus other than is supplied by the tumour; or we may find that any movement conveyed to the tumour by the hand examining the abdomen is at once conveyed to the cervix itself, the tumour and the cervix moving *en masse*. The next information that we shall have readily to hand, supposing we take our first group, is the history of menstruation. That will at once give us certain other indications to go upon.

(a) We will take a case where we may suppose there is amenorrhœa, and we will begin with a case in which the amenorrhœa has followed a period of normal menstruation. Our diagnosis is now three-fourths made. Amenorrhœa, following on normal menstruation, is due to pregnancy in 99 per cent. of cases. As we are satisfied that the tumour is uterine, if in addition there are symptoms of pregnancy, we may say it is a case of normal pregnancy. The amenorrhœa may have been followed by a period of irregular hæmorrhage, and we shall very likely find that the uterus, instead of presenting the usual elastic feel of a normal pregnancy, is rather harder and more boggy, and that the external os is partly dilated. In that case we shall say it is not a normal pregnancy, but probably a case of missed abortion—that is to say, when the hæmorrhage started the fœtus died, and the uterus should have got rid of it, but did not, and so it comes under the category of missed abortion. But the amenorrhœa may be of a different type, for the patient

may never have menstruated at all. It may be a primary amenorrhœa. In that case, supposing that we find that the external os is more or less obliterated, that there is, in fact, atresia, as is quite likely in such a case, and supposing there are no symptoms of pregnancy at all, we may fairly certainly conclude that this is a case of retention of menstruation due to atresia of the os, and we shall call it hæmatometra. It is a point to remember that after a patient has menstruated the external os may get obliterated as a result of disease, and hæmatometra may thus form in a secondary fashion. But that is too rare to be taken into practical account. I have only seen one such case, and probably most men do not see more than two or three in a lifetime.

In all these cases we have supposed that the uterus is in the normal position, and feels practically like a pregnant uterus, which hæmatometra may closely resemble. But we may find the uterus retroverted, and this gives us a further variety in this group of cases of amenorrhœa: with symptoms of pregnancy and a further history of bladder trouble, culminating in retention of urine, our diagnosis will be retroversion of the gravid uterus.

(b) If a patient has amenorrhœa and an enlarged uterus, it is practically certain to be one of those conditions I have mentioned. But we may find, in the cases under consideration, that, instead of there being amenorrhœa, menstruation has increased; there may be menorrhagia or metrorrhagia. When there is a definite increase in the size of the uterus, accompanied by menorrhagia over any considerable time, or accompanied by hæmorrhage in the intervals of menstruation, without any previous period of amenorrhœa, you may be quite certain that that uterus is the seat of a fibroid tumour, or of some modification of a fibroid, such as fibro-adenoma. It is usually impossible to distinguish between fibroid and fibro-adenoma, or, as it is sometimes called, diffuse adeno-myoma, until you open into the uterus. Though adeno-myoma is usually rather softer than true fibroid, the latter may be undergoing some degeneration, and will then feel like adeno-myoma.

(c) There is a third class, in which menstruation is not regularly increased, but there is irregular hæmorrhage. Supposing you have a case with a history of irregular hæmorrhage, pain in the pelvis, rise of temperature, and on examining you find that the uterus is very large, and in addition that there is a carcinoma of the cervix, your diagnosis is not quite complete when you have said it is a case of carcinoma of the cervix; because it is almost certain that in addition, with a large body of the uterus, if the enlargement gives a sense of fluctuation, you have to do with a case of pyometra—i.e., pus retained in the uterine cavity. Pyometra hardly ever occurs except in conjunction with carcinoma of the cervix. Carcinoma of the cervix by itself does not produce any material enlargement of the uterus. If there is any enlargement of the uterus in a case of carcinoma of the cervix, the enlargement is due to something else; it may be to pyometra, or to a conjunction of carcinoma with fibroid. By this means we shall practically have analysed all our cases of pelvic tumours which are definitely uterine.

II.—Our second group is that in which the tumour is definitely not uterine. And here again, having found the tumour, the first thing to inquire into is the menstrual history, which will at once give us some important clues.

(a) As before, we begin with the class where there

(a) Delivered at the Polyclinic, Charles Street, London, W.C., on Wednesday, June 23rd, 1909.

is amenorrhœa. That always suggests pregnancy, and if there is a tumour apart from the uterus, extrauterine pregnancy. The tumour may be either mobile or fixed. (1) Take first the case in which there is a mobile tumour, not uterine, associated with amenorrhœa. Of course, the uterus itself may be pregnant and there may be a tumour; but I am not considering that, because it would come under the last group, that of more than one swelling. If you get a case of a normal uterus with a mobile swelling on one side and amenorrhœa, you will almost always find that the amenorrhœa is of not more than two months' duration. You may diagnose this as unruptured tubal pregnancy. These cases which are diagnosed are few and far between, and the principal reason is that in such a case there is but little in the way of symptoms. The patient misses one or two periods, and, thinking she is pregnant, does not think it worth while to consult a doctor. And if she does go and ask him to attend her in seven months' time, he will not think it necessary then to examine her. So many of these cases pass unnoticed. But if you do examine such a case at this early stage, you can make this diagnosis with tolerable certainty. An unruptured tubal pregnancy will nearly always be laterally situated. Occasionally the tumour may be lying on the front, or towards the back of the uterus, but the lateral position is the more common.

(2) Then there is the case where the swelling is fixed. This fixed swelling may be either to one side of the uterus or behind it. If it is lateral and fixed, and there has been amenorrhœa, you will almost invariably find that there is, after the amenorrhœa, a period of slight hæmorrhage. You will say this is almost certainly a tubal pregnancy; and when it is fixed it means that rupture has taken place. After such rupture the tumour is never mobile. About ten or twelve years ago I saw a patient who gave a history of two months' amenorrhœa. She had a great deal of pain, referred to one side, and a little irregular bleeding; and on examining I felt, I thought, a swelling on one side of the cervix. But I did not feel clear enough about it to advise operation; I thought it better to wait. I tried to push up the swelling, and found that it moved a little. I saw the case again a fortnight later, and then the swelling was no longer lateral; it clearly formed part of the uterus, which was in a fairly good position. We diagnosed that it was pregnancy, with probable abortion, and she confirmed our diagnosis a fortnight later. If that case were to occur to me now—knowing more than I did then—I could not suppose that was a case of tubal pregnancy, because it was mobile. If it had been ruptured it would have been fixed. It could not have been tubal pregnancy unruptured because there was hæmorrhage, and it was that hæmorrhage which made me think it was tubal pregnancy.

The lateral tumour, which is fixed, is almost certainly in the broad ligament. The case is one of mesometric pregnancy. Of course, mesometric pregnancy may not be progressing as a pregnancy, because the fetus may die. But in either case it is conveniently so described. If, however, the tumour is posterior, you may describe it as hæmatocele due to a tubal pregnancy. That may be the result of a rupture of the tube, causing hæmorrhage into the peritoneal cavity, or a tubal abortion causing bleeding through the open fimbriated end of the tube. I do not think you could say before-hand which of the two it is.

(3) Take now the second class, in which menstruation is unaltered. How shall we divide these cases in which menstruation is not altered and there is a swelling in the pelvis? Perhaps the most convenient plan will be to divide them into two divisions: swellings which are mobile, and those which are fixed. (1) Take first the mobile ones, we find there are not a great many of them. There may be a small ovarian, which has a reasonable pedicle, and is able to move about, and it may be in front of the uterus, or behind, or at the side. In most cases a quite small one is more or less at the side, and as it enlarges it gets a little behind, and when it grows larger still and grows out of the pelvis, it gets on the top of the

uterus, pushes that down, and it lies in front or above the uterus. An exactly similar position may be occupied by a small pedunculated fibroid, which may be attached to the uterus behind, in front, or at the side; and the only way you can distinguish between pedunculated fibroid and ovarian is by the consistency. If you find the tumour is cystic and elastic, you may conclude it is a small ovarian. If it is very hard it is probably fibroid. I have put this among the cases of menstruation unaltered, because as a rule pedunculated fibroid does not affect menstruation at all. There may be, in addition to the tumour which you feel, a second one in the uterus, causing hæmorrhage; and if you do find that, it helps your diagnosis very much, because if there is hæmorrhage and a tumour outside, the probability is that there is one fibroid in the uterus and another you can feel outside it.

There are one or two other mobile swellings which you may find it necessary to differentiate from these. If the swelling is on the left side, and instead of being spherical and elastic or hard and spherical, it is somewhat irregular in outline and somewhat doughy in consistence, you may quite well be dealing with carcinoma involving the sigmoid or the rectum. Probably the carcinoma of the rectum, by the time you feel it, will almost always be fixed; but carcinoma of the sigmoid may have a considerable range of movement, and may come under the category of mobile swellings. That would be on the left side. Again, there may be a mobile swelling in front of the uterus, which you have to distinguish from other things, namely, foreign body in the bladder. It is possible to have such a tumour of the bladder itself, giving the impression of a mobile swelling in the utero-vesical pouch. If you had a doubt you would pass your bladder sound, and settle it in that way. Lastly, either in front or behind the uterus, you find an elongated swelling, sausage-shaped, not very resistant. You can depress it pretty easily, and next time you examine, it is gone. In such a case you may find you have to do with distended coils of bowel. When you are examining at the front or behind the uterus, it does not occur to you that there is bowel there which you can feel so plainly. If you can feel such tumour it is well not to give the opinion that the patient has a tumour until you have waited to see the effect of time and treatment.

(2) We will now pass on to the second division, that of fixed swellings. These present rather more variety than do the mobile ones. And it will be convenient to divide them into tumours which are lateral, those in front of the uterus, and those which are behind.

(i) The lateral ones are the most interesting and numerous. A lateral swelling in the pelvis, more or less fixed, may vary in consistence. If it is spherical and elastic you will almost certainly find that it is a cyst of some kind. It may be a broad ligament cyst. Or it may be an ovarian cyst which is impacted in the pelvis without any complication beyond the impaction. In both these cases the temperature will be normal. The patient may have some pain, and probably nothing else; you merely find a cystic swelling at the side of the uterus. There are other cases in which the pain may be very considerable, with more or less rise of temperature. If you find a fixed globular swelling at the side of the uterus, with a rise of temperature and pain in the pelvis, you can go further in your diagnosis, and say you have to do with an inflamed and adherent ovarian cyst. Supposing it has come on quite acutely, a sharp pain being experienced, whereas previously the patient was fairly well, and you find this tense and tender swelling quite fixed, you can diagnose ovarian cyst with twisted pedicle.

If, instead of the swelling being nicely rounded and globular, it is irregular, and perhaps ovoid in outline, it is probably dilated tubes; and they may be dilated either by clear fluid in the form of hydrosalpinx, or by pus in the form of chronic pyosalpinx. The difference between these and the ovarian tumours will be largely in the form of the swelling which is felt. If there is a temperature and a rather irregular swelling by the side of the uterus, tender on pressure,

it is very likely to be inflamed appendages. But you may find the swelling is quite hard, and if it is also rounded, it may be fibroid of the broad ligament. Further, there may be a hard swelling by the side of the uterus, but not so well defined, and if the patient has a temperature, and very likely rigors, you may diagnose it as pelvic cellulitis. A patient may have a considerable amount of pus in the broad ligament, namely, true pelvic abscess, and yet you may not be able to feel a softening of the abscess at all; it may feel hard and board-like, because the broad ligament may be so much thickened in the part which you can reach from the vagina that you cannot detect anything approaching fluctuation.

But the swelling may be neither cystic nor very hard; there may be no temperature. But you may find an irregular doughy kind of swelling, such as we mentioned just now in connection with carcinoma of the rectum. So if you are examining a patient and you find the left side somewhat irregular, and there is a fixed semi-solid tumour there, and you are not satisfied about its character, you will do wisely to put one finger into the rectum; it will save you many a retraction of opinion afterwards. Ovarian tumour is eminently operable and curable; but carcinoma is another thing, and it may not be amenable to operation at all.

(ii.) Now, suppose the swelling is a fixed one, in front of the uterus. That may be cystic, and then it cannot very well be anything but bladder. I put it down here so as to remind you of the advisability of passing a catheter in all cases of doubt; sometimes a little delay in passing it causes inconvenience. Some time ago I got a message from a friend in the country asking me to hold myself in readiness to do an operation for a large cyst, and two days later I heard that all was well, as a catheter had been passed, and about 80 ozs. of urine had been drawn off. But meantime the patient had been informed that there was a cyst there, and the subsequent explanation in such a case is always awkward.

Instead of being cystic, the tumour may be hard, and then it will almost certainly be a fibroid, developing in the anterior part, and pushing up the bladder; it will be a rounded, smooth swelling. But you may get a hard tumour of irregular outline, and in the latter case it is very apt to be carcinoma of the bladder.

I would like to digress here to tell you of a curious group of three cases which came to my notice. The first patient was passing faecal matter and pus by the bladder. We cystoscoped her, and saw a ragged, ulcerated surface in the bladder. There was a hard swelling to be felt a little to the left, and we concluded it was probably abscess in the pelvis, that communicated with both bowel and bladder. We opened her up, and found the sigmoid densely adherent to the bladder. It was true she had a small ovarian abscess on the left side, but it had no relation to the bladder at all. On separating the bowel from the bladder, the bowel felt very hard. She was a single woman, æt. 28, and as the bowel looked suspicious I thought I would resect it. It turned out to be carcinoma of the sigmoid, adherent to the bladder, and ulcerating into it. I did not know what it was at the time, or I should probably have removed part of the bladder wall, but now, fifteen months after the operation, she is all right.

The second patient was passing faecal matter by the bladder, and I opened her up and found carcinoma of the sigmoid. She was older than the last patient, and there was an extensive growth, adherent to and invading the base of the bladder, so one could not do anything for her. I take it such a state of matters is fairly rare. Yet five weeks after that I saw another case almost exactly similar, in which carcinoma of the sigmoid was continuous with a growth of the bladder which infiltrated the whole base and sides of it, so that it was like a cup.

(iii.) In the third group, the swelling is fixed and behind. And these swellings which are behind are very similar to those which are lateral; that is to say, you may have an inflamed ovarian behind, an

adherent impacted ovarian, an ovarian with twisted pedicle; there may be pyosalpinx, or there may be an impacted fibroid adherent to the back of the uterus; and, lastly, there may be intrapelvic abscess, causing an irregular boggy swelling behind the cervix. So these conditions behind are very like those at the side, and the same principles will hold fairly well with regard to them.

(c) For the sake of symmetry, we ought to include in our second group a third class, in which menstruation is increased. But when menstruation is increased and there is a swelling in the pelvis, that increase may have no significance in connection with the diagnosis of the swelling. But sometimes it has, and the pelvic swellings in which you find increase in menstruation are three: (1) fibroid, (2) pyosalpinx, (3) carcinoma of the ovary. In most cases there is no means of distinguishing between a solid ovarian and a pedunculated fibroid; but in both these cases the tumour will be more rounded and defined than is the case with pyosalpinx.

III.—There is a third group, in which it is doubtful whether the tumour is uterine or not. It is almost always possible to feel the cervix, and even if the cervix is drawn up behind the pubes, you can almost always tell its position. So, in a doubtful case, take the cervix as your starting-point, and consider whether the tumour is behind the cervix, by the side of it, or above it. If it is behind, consider how menstruation is. If there has been amenorrhœa, it must be one of two things—either retroversion of a gravid uterus or an extra-uterine pregnancy developed in the pouch of Douglas. If there has been no amenorrhœa, and you are satisfied it is not pregnancy, you pass the sound, when you can tell whether you are going into the tumour or not. In this way the case is transferred to one or other of our first two groups. In a doubtful case go first of all for the question of pregnancy. If the tumour is at the side of the uterus, ask whether it is pregnancy or not. If it is pregnancy, it must be extra-uterine. If there is no pregnancy and no amenorrhœa, pass the sound to clear the matter up.

IV.—I want to say a word about the last group—cases in which there is more than one tumour—because those are often very difficult cases. I will give you a list of the possibilities, and we can then consider what are the guiding principles.

If there are two or more swellings in the pelvis, one of them may be pregnancy and the other may be a fibroid, an ovarian, or an extra-uterine pregnancy. Of course, there may be pregnancy complicated by an appendix abscess, but in that case the two things would be pretty clear; there would be a history of the pregnancy and of an attack of appendicitis. But when a pregnancy is complicated by fibroid, it is difficult, as the fibroid should cause menorrhagia, but the super-vention of the pregnancy may cause amenorrhœa. With pregnancy there should be amenorrhœa, but if there is a fibroid there may be hæmorrhage. But if you find the tumour varies in consistency in different parts, you have to consider the possibility of there being a combination of the two. If the tumour is quite independent of the uterus and is cystic, probably it is ovarian. It is curious how often dermoids complicate pregnancy; they do so in a surprising number of cases.

With regard to intra-uterine and extra-uterine pregnancies, there are signs which may belong to either. Generally with intra-uterine pregnancy co-existing, you get no hæmorrhage from rupture of the tube; consequently you lose one of the chief signs of extra-uterine pregnancy. Practically your only guiding sign would be: supposing a patient with pregnancy were to develop the symptoms of intra-peritoneal rupture of a tube, with intra-peritoneal hæmorrhage and lateral pain, and you found that pregnancy was apparently not affected, you might diagnose pregnancy in association with ruptured pregnant tube. But if you are able to diagnose this, you may consider you are lucky in most cases, as well as skilful.

There may possibly be ovarian complicating fibroid tumours. When a number of hard swellings are felt, one probably diagnoses multiple fibroids; yet it may turn out that some of the swellings are ovarian in origin. Of course, with solid ovarian tumours the

mistake is very easily made, but even ovarian cysts may simulate fibroids.

In one such case that I came across there were fibroids and a suppurating ovarian cyst with carcinoma in its walls, and malignant deposits on the back of the uterus also. That is a kind of thing which no man could diagnose beforehand. There may be an ovarian with extra-uterine pregnancy, or with pus tubes; or there may be fibroid with extra-uterine pregnancy, or fibroid with pus tubes. The last combination is not very uncommon. When there are pus tubes with an ovarian cyst, the probability is that the pus tubes will be the predominant partner. When there are a fibroid and pus tubes, it will be the fibroid which will be the striking feature, and the pus tubes will only be discovered during the operation, unless there happens to be some rise of temperature at the same time. There may also be multiple fibroids, and there may be double ovarian tumours. And, lastly, there may be fibroid or ovarian, *plus* some malignant growth of the bowel or omentum. Broadly speaking, these things are not diagnosable, and there is not time to go into them in detail to-day. They are almost always discovered accidentally in the course of the operation.

The following synopsis will serve to illustrate the method that can be followed in arriving at a diagnosis. It does not, of course, embody all the data that have to be considered in a given case, nor is diagnosis quite such a simple matter as is here indicated; consequently, the synopsis must not be regarded as more than a guide to a method.

#### SYNOPSIS OF THE DIAGNOSIS OF PELVIC TUMOURS.

##### I.—The tumour is uterine.

- (A) There is amenorrhœa.
  - (1) The amenorrhœa follows normal menstruation.
    - (a) Uterus in normal position, elastic, large—normal pregnancy.
    - (b) Uterus retroverted, elastic, large—retroversion of the gravid uterus.
  - (2) The amenorrhœa was followed by hæmorrhage.
    - (a) Uterus in normal position, doughy, os patulous—threatened abortion.
  - (3) The amenorrhœa is primary.
    - (a) Uterus in normal position, atresia of the os externum—hæmatometra (retained menses).
- (B) There is menorrhagia or metrorrhagia.
  - (1) The uterus is large, very hard—uterine fibroid.
  - (2) The uterus is large, soft, with carcinoma of the cervix—(?) pyometra due to carcinoma.

##### II.—The tumour is not uterine.

- (A) There is amenorrhœa.
  - (1) The tumour is mobile, lateral, or in front of the uterus—unruptured tubal pregnancy.
  - (2) The tumour is fixed, lateral, or behind the uterus—ruptured tubal pregnancy.
- (B) Menstruation is unaltered.
  - (1) The tumour is mobile.
    - (a) The tumour is cystic, lateral (? in front or behind)—small ovarian cyst.
    - (b) The tumour is hard, in front behind or lateral—pedunculated uterine fibroid.
    - (c) The tumour is firm or doughy, on left side—carcinoma of the sigmoid.
    - (d) The tumour is in front, firm, with *ballotement*—foreign body in the bladder.
    - (e) The tumour is in front or behind, vague shifting—distended coils of bowel.
  - (2) The tumour is fixed.
    - (i.) The tumour is lateral.
      - (a) The tumour is cystic, globular, temperature normal—broad ligament cyst; impacted ovarian cyst.
      - (b) Tumour cystic, globular; temperature raised—inflamed ovarian cyst; ovarian cyst with twisted pedicle.
      - (c) Tumour cystic or firm, ovoid or irregular—hydrosalpinx; chronic pyosalpinx.
      - (d) Tumour hard, rounded; temperature normal—fibroid in the broad ligament.
      - (e) Tumour hard, board-like, vaginal vault involved—pelvic cellulitis or abscess.

(f) Tumour doughy or pitting, irregular, on left side—carcinoma of the rectum; fæcal matter in the rectum.

(ii.) The tumour is in front.

(a) Tumour cystic, disappearing with the catheter—distended bladder.

(b) Tumour hard, rounded—uterine sub-peritoneal fibroid.

(c) Tumour firm, irregular; hæmaturia—carcinoma of the bladder.

(iii.) The tumour is behind.

(a) }  
(b) } As with lateral tumours.  
(c) }

(d) Tumour hard, rounded—impacted fibroid sub-peritoneal.

(e) Tumour not well circumscribed; temperature raised—intra-pelvic abscess.

(C) There is menorrhagia.

(1) Tumour hard, rounded, lateral or behind; temperature normal—impacted fibroid and fibroid in uterus.

(2) Tumour hard, rounded, or irregular; wasting; hydro-peritoneum—ovarian carcinoma.

(3) Tumour firm, irregular, or ovoid; temperature raised—pyosalpinx.

##### III.—It is uncertain whether the tumour is uterine or not.

(a) There is amenorrhœa.

(1) The tumour is above the cervix—pregnancy uterine.

(2) The tumour is behind or to the side of the cervix.

(a) The tumour is mobile—retroversion of the gravid uterus.

(b) The tumour is fixed—ruptured tubal pregnancy.

(b) Menstruation is unaltered.

Pass the uterine sound, and see whether it goes into the tumour or not; this will at once enable you to assign the tumour to Group I. or II.

##### IV.—There are two or more tumours.

No definite rules can be laid down. The possibilities are:—

Pregnancy *plus* ovarian cyst.

Pregnancy *plus* fibroid.

Pregnancy *plus* pus-tubes.

Pregnancy *plus* tubal pregnancy.

Ovarian cyst *plus* fibroid.

Ovarian cyst *plus* pus-tubes.

Ovarian cyst *plus* tubal pregnancy.

Fibroid *plus* pus-tubes.

Fibroid *plus* tubal pregnancy.

Multiple fibroids.

Double ovarian tumour.

Double uterus.

Uterine or ovarian tumour *plus* malignant tumour elsewhere.

**NOTE.**—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Drs. Maurice Loeper, M.D., and Xavier Gouraud, M.D. Subject: "Decalcified Dietary in Arterial Atheroma."

An outbreak of beri-beri has occurred on board the Brazilian cruiser *Carroza*, which has arrived in the Tyne bringing men for the new battleship being built there for the Brazilian Government. It was found necessary for the Tyne Port Sanitary Authority to remove five men to the floating hospital suffering from the disease, and one of them, a young man of 22, has died.

An alarming outbreak of illness in Bristol was reported, on the 7th inst., by the medical officer, Dr. Davies, at a meeting of the Health Committee. Out of sixty-nine persons who had eaten corned beef and pork bought from a local tradesman sixty-one were taken ill, more or less seriously, but no fatal cases had occurred.

## ORIGINAL PAPERS.

# CONGENITAL HEART AFFECTIONS, ESPECIALLY IN RELATION TO THE DIAGNOSIS OF THE VARIOUS MALFORMATIONS. (a)

By GEORGE CARPENTER, M.D.,

Physician, Queen's Hospital for Children; Vice-President, Royal Society of Medicine; Membre Correspondant de Pédiatrie de Paris.

THE coincidence of congenital malformations of the heart with malformations in other regions of the body is a matter of everyday experience. Heart malformations are not always accompanied by other congenital bodily defects, but they are sometimes found in association with such diverse structural faults as hare-lip, cleft palate, ill-developed teeth, supernumerary auricles, and supernumerary nipples, polydactylism, syndactylism, webbed fingers, steeple-skull, defects in the abdominal wall, herniæ, ill-developed and absent rib cartilages, undescended testis, atresia of the anus and rectum, postanal dimple, congenital opacity of the cornea, coloboma iris, congenital defects of the orbits, congenital ptosis, not to mention many other congenital irregularities of development which are obvious to the naked eye—cretinism, for instance—which sometimes bear them company.

Of internal mal-developments which are not obvious on inspection there are numerous illustrations, such as unilateral kidney, horse-shoe kidney, double ureters, absent spleen, supernumerary spleens, malpositions of the intestines, atrophic patches in the choroid, transposition of the viscera, four lobes to the lungs, and an accessory bronchus amongst other anomalies.

Deaf-mutism is sometimes an associated condition, and the coincidence of Mongolian imbecility with congenital heart malformations has been variously recorded by cases and morbid specimens.

That congenital malformations of the heart are sometimes hereditary has been proved by several observers—Ferrannini, De la Camp, Orth, and others—who have recorded examples of this as a family complaint. Among my own series I have illustrations of two cases in the children of one family, and of three cases in the children of the other. Among the latter, one, an example of steeple skull came to autopsy, and the heart, like the child, was fantastic, and could not be placed in any usual anatomical grouping. The foramen ovale was widely open and divided into two by a bridge of tissue. Behind this was another hole in the septum, and above this hole the septum was minutely fenestrated. The right auricular appendix was very large and muscular,  $1\frac{1}{2}$  in. long by  $\frac{3}{4}$  in. broad at its broadest part, and it and its corresponding auricle made an elongated chamber about 2 in. long and a little more than  $\frac{1}{2}$  in. broad behind. The tricuspid orifice was small,  $\frac{3}{16}$  in. only, with natural though small valves, and passed into the cavity of the right ventricle, which was so small that it would only admit a pea. The pulmonary artery was smaller than the aorta, and was situated directly over the ventricular cavity. The thickness of the ventricular wall was  $\frac{3}{16}$  in., and at its upper and outer part was a distinct muscular hump, on which the enlarged auricular appendix rested. The left auricle was more muscular than natural, and the left ventricle was enormously hypertrophied, its walls measuring  $\frac{7}{16}$  in. thick, which so encroached on its cavity that its capacity appeared to be even less than that of the right. The mitral orifice, which was larger than the tricuspid, was  $\frac{5}{16}$  in. across, and its valves were natural. The aorta, which had a right-angled bend on it like that of a ventilating shaft on a steamer, was thick walled; its valves were normal. The greater part of the heart was made up of the left ventricle and the right auricle and appendix. There was no bruit during life.

Since heart malformations have been shown to be a family complaint in some instances, it must be

admitted that inherited as well as acquired defects in the sperm and germ-cells of the parents are of some importance in the production of malformations of the heart, as in other regions, for erratic tendencies to produce deformities when once acquired are handed down from parents to children.

Inquiry has been directed to the state of the mother's health, both bodily and mental, during the pregnancy to serve as an explanation for the production of congenital cardiac defects. Maternal impressions and trivial injuries have been, and are still frequently, advanced to explain away congenital anomalies of the heart and elsewhere, because mothers have been brought up in such beliefs, and readily recall all sorts of strange sights and slight mishaps incident to the pregnancy, if it be the misfortune of the offspring to present any abnormalities of mind or body. When it is realised that the heart is perfectly formed, though in miniature, in seven weeks' time from the date of conception, the various examples of congenital heart disease that have been recorded by J. Lewis Smith and others, following upon frights and so on during the last two or three months of pregnancy, these psychical disturbances cannot possibly have had any effect upon the foetal heart. Maternal impressions must, I think, be thrown into the waste-heap of other ill-founded superstitions.

But it is otherwise when the bodily health of the mother becomes the subject of scrutiny. In regard to definite illnesses affecting the mother during the pregnancy, it is surprising how few mothers give a history of suffering any illness during that period. In 100 examples of my own of congenital malformation of the heart, in a large number the parents and their families were apparently free from rheumatic taint, as no history of that complaint was admitted. In a few instances the parents had suffered from rheumatic fever, but in no case was there any evidence in this series of maternal rheumatic fever taking place during pregnancy. Therefore the commonest cause for endocarditis in children was conspicuous by its inconspicuousness in my pre-natal cases. But Theodore Fisher (1) narrates that in a case of foetal endocarditis, three months before the birth of the infant the mother suffered from severe pain in the left knee, and for several days she could only get about the house with difficulty. This fact is of importance, because it shows that rheumatic fever in the mother is not essential to the production of foetal endocarditis, and it suggests that those painful bodily ailments in the mother during the carrying, which are grouped under the generic term "rheumatic," may be the cause of foetal endocarditis in the infant.

Endocarditis in the foetus has been attributed to typhoid fever, influenza, pneumonia, and other maternal infections. But these diseases arising during the pregnancy are infrequent in comparison with the number of cases of foetal endocarditis for which a ready explanation is not forthcoming.

Syphilis, of course, is naturally uppermost in the mind as an explanation for congenital affections of the heart, but it does not appear to be a very important factor in the creation of cardiac abnormalities. The number of congenital syphilitics that I have seen with congenital heart malformations has been very few; and the number of my cases of congenital heart disease that could be ascribed to syphilis was trifling—only three. Bearing upon this question, it may be noted that Hochsinger found congenital heart disease only 7 times in 500 cases of congenital syphilis.

There is a strong presumptive evidence that alcohol has a decided influence in the production of deformities, and clinical experiences are borne out by experimental observations on the lower animals. In Hodge's experiments, where alcohol was administered to two parent dogs, of twenty-four puppies born, many were deformed or dead. Féré, also, in controlled experiments on chicken's eggs exposed to the vapour of alcohol, found that a number of the chicks were found dead or stillborn, and displayed various deformities.

That immoderate drug-taking may be a cause for congenital abnormalities I have an example in the person of a lady who was a confirmed morphino-

(a) Abstract of the Wightman Lecture for 1909, delivered at the Royal Society of Medicine, June 24th, 1909.

maniac at the conception and during the pregnancy, and with the result that an imbecile child was born to her.

Tuberculosis in the parents has been credited with the production of hypoplasia of the aorta.

Several examples of foetal endocarditis have been shown to the Society for the Study of Disease in Children, or have been spoken of at its meetings. Theodore Fisher's case (2) of aortic disease occurred in a child, aged 4 months. The flaps of the semilunar valves were much thickened and adherent. Some thickening of the flaps of the mitral valve and its chordæ tendinæ was also present. G. W. Nash, of Bedford, at the same meeting, narrated a case of a child who died, aged 6 months, from mitral stenosis. The mitral valve was puckered and diminished. This he attributed to sepsis from defective drainage, as the mother developed pneumonia from that cause after the confinement. In a case reported by the late A. E. Sansom (3) in a baby, aged 2 months, there was a ring of granulations of endocarditis, and the mitral valve was thickened. The changes were of the rheumatic character, but the mother, so he stated, had never suffered from rheumatism, and he went on to say that endocarditis in intra-uterine life was so rare that it was desirable that every case should be reported. At a later meeting during the same session, Fisher (4) showed the heart of an infant, aged 4 months, in which the aortic and pulmonary valves displayed large organised vegetations. There was an intra-pericardial septal defect between the pulmonary artery and aorta, which extended downwards into the upper part of the septum ventriculorum. The pulmonary artery had two valves, and the cardiac defects were associated with somatic defects in the shape of a hare-lip and the rectum and vagina sharing a common aperture. Fisher attributed the endocarditis to defective house drains during the pregnancy. In Ayrolle's case (5) there was marked stenosis of the mitral valve, on which appeared numerous endocarditic vegetations. The infant died ten days after its birth. In a case recorded by Cotton (6), granulations were present both on the mitral and on the cusps of the aortic valve.

Planchu and Gardère (7) have recently recorded a case of endocarditis of the pulmonary artery in an infant, aged 6 weeks. The artery was bivalved, the lower surface of the cusps being rugose and showing numerous vegetations and ulcerations. The cardiac septa were so defective that the organ was practically one of two chambers. The great vessels were transposed, and the pulmonary artery was very narrow, and would only admit a small sound. There were associated visceral defects. In the heart of an infant, aged 25 days, recently exhibited by André Moussous, (8) the mitral valve showed signs of recent endocarditis. The orifice of the pulmonary artery was obliterated by a membranous arched diaphragm produced by the coalescence of the sigmoid valves. Above the tricuspid in the cavity of the auricle there was a pre-orificial narrowing in the shape of a rigid ring hardly admitting a goose-quill. The foramen ovale valve had a fenestrated appearance.

Foetal heart murmurs have been recorded by various writers. Tricuspid regurgitation has been detected *in utero* by Peter (9) who heard a systolic bruit replacing the first sounds of the heart. The child was stillborn. The tricuspid valve was covered with vegetations and tied down by shortened chordæ tendinæ. Hochsinger (10) quotes two cases, those of Barth and Hennig. In the former the child was also stillborn, and there was endocarditis of the tricuspid valve. In Hennig's case a double murmur was due to endocarditis of the aortic valves. In Christopher's case, reported to the American Pediatric Society, the aortic and tricuspid valves showed verrucose thickening, and the pulmonary artery took origin from the aorta. In Wetherill's case (11) the murmur persisted after birth, and was attributed to stenosis of the pulmonary artery, while in Hall's case (12) the bruit disappeared and was ascribed to patent ductus arteriosus, which became obliterated.

In the production, therefore, of congenital affections of the heart, two distinct processes can be seen in action—viz., development disturbance and inflamma-

tion. Both can operate without the other, and both are frequently combined. Those mal-influences, inherited and acquired, which preside over the sperm and germ-cells, have been passed in review, as also the causes of foetal endocarditis. The results of foetal endocarditis are seen in the shape of sclerotic valves, and on these valves it is not uncommon to find recent endocarditic vegetations. It also frequently happens that in association with congenital developmental anomalies the mitral and tricuspid valves are found to be somewhat thickened and crumpled at the edges, though perfectly efficient, suggesting that they have undergone a mild endocarditis during foetal life. It is in stenosis of the pulmonary artery that valvulitis and anomaly are so frequently combined. The points at issue are these: Are the patent septum ventriculorum and the atrophied pulmonary artery the result of increased blood-pressure in the right ventricle and starvation of the artery—that is, purely mechanical, or are the defects in the artery and the septum ventriculorum of developmental origin, and the endocarditis of the pulmonary valve an indication of its increased liability to attack by reason of developmental anomaly?

#### MORBUS CÆRULEUS.

*Morbus cæruleus* and congenital malformations of the heart have been looked upon as synonyms, but without reason, for children with severe congenital morbus cordis are frequently not blue, even when excited or crying. Many verified cases of congenital morbus cordis have been recorded where cyanosis was not a symptom during life. On the other hand, chronic lung (13) disease may be associated with extreme and chronic cyanosis, a characteristic example of which I exhibited to the Society for the Study of Disease in Children in 1906.

Some children with congenital morbus cordis are fresh-coloured. Others are strikingly pale. In some the lips are dark crimson, perhaps inclined to blueness rather than redness, or to turn lilac on crying. Or the complexion may be quite good and only the fingers dusky and cold-looking. The majority, however, are cyanosed more or less, and all gradations of cyanosis may be noticed, from that of a dark rubicund face with similar coloured ears and reddened finger and toe-tips, or a state of rather dusky-blue lips and cheeks and tongue and a similar condition of the extremities, to one where the face is plum-coloured, the conjunctivæ suffused, the buccal mucous membrane and tongue the colour of a slate, and the body generally dusky. In the majority of those who are blue the cyanosis dates from birth, but in others the children show no signs of blueness until after an attack of one of the exanthems, or following bronchitis or broncho-pneumonia, with or without whooping-cough.

Increase of cyanosis in those already blue and of paroxysmal onset is sometimes a symptom. In one cyanosed infant of mine, aged 2 months, who developed paroxysmal cyanosis, it was associated with a loud systolic bruit audible all over the front and back of the chest, and most marked at the second right cartilage. In another infant, aged 1 month, the only lesion that I could find after death was a patent foramen ovale. During the attacks that I witnessed in these infants the pulse, which was at first rapid, became gradually and quickly slower, and the breathing, which had been accelerated, ceased, and the infant remained for several minutes in a state of complete apnoea, during which time the cyanosis became extreme in the face and lips and tongue, and on the body and limbs. The conjunctivæ were insensitive and the pupils slightly contracted. If left undisturbed after some four or five minutes the infant gasped, the breathing recommenced, the colour returned and the eyes were opened, only to be followed in about half-an-hour by a recurrence of the same symptoms. Attacks such as these suggest to my mind a central origin, possibly of the medulla, for they bear some resemblance to attacks of unexpected cyanosis and apnoea which sometimes take place during the course of tuberculous meningitis, and with a suddenly fatal result. Such patients can certainly be temporarily revived, and perhaps on several occasions, if their

paroxysms of cyanosis are treated by artificial respiration. Morrow (14) has described recurrent cyanosis associated with very shallow respiration in two infants. One child, at the time of the report, was living and well. The other, a premature infant, died of asthenia, but there was no post-mortem. Morrow quotes Holt as having described similar symptoms in infants in whom atelectasis was found at autopsy.

Leconte (15) has reported two examples of paroxysmal cyanosis in children of three-and-a-half and four-and-a-half years old, which appeared for the first time in the first case a month previous and in the second child at two years of age.

Variot, under the term "congenital intermittent cyanosis," has drawn attention to the onset of cyanosis under exciting conditions, energetic movements and forced expiration.

Cyanosis becomes aggravated when dilatation of the right ventricle takes place, and the veins of the body become overcharged with blood. Microscopical examination of the organs (16) shows extreme capillary dilatation, with thickening and a tendency to fibrillation, as also venous engorgement and thickening in the brain, kidney, liver, heart, and elsewhere. I examined many microscopic sections of the skin of the patient, some twenty years ago, from whom this description of the capillaries is taken, but I found no capillary dilatations there. Hochsinger (17) states that the skin capillaries are dilated and tortuous in these cases, especially in the peripheral parts of the body. So wide and so tortuous were the vessels in the case I examined, that while, for instance, in the kidney the afferent arteries of the Malpighian corpuscles admitted but two or three red corpuscles abreast, the enormously dilated afferent veins contained seven or eight more. Loutaud states that the veins are not only dilated, but have hypertrophied muscular walls. The infrequency of general oedema in congenital cyanosis in children has been ascribed to this hypertrophy. But this absence of oedema occurs in acquired heart disease in children, and is not peculiar to congenital heart disease, and I have also met with several examples of oedema in the last stages of congenital heart disease in spite of these structural alterations in the veins and capillaries.

By far the most common malformations of the heart in association with cyanosis are those cases where the pulmonary artery or the conus are either absent, rudimentary or constricted. Next in frequency in the list of malformations, though only to about one-seventh of their number, is transposition of the pulmonary artery and aorta. Apart from these mal-developments, which form the bulk of congenital cardiac anomalies, the malformations which give rise to cyanosis are numerous and various.

Various views have been and are still held as to the causation of cyanosis, the criticism that I have to make about them being that it is sought to explain all cases of cyanosis by one theory, whereas the cause is often complex and differs in different cases.

The oldest theory, that of venous stasis, is that of Morgagni, which has numerous adherents. Another view is that cyanosis is due to the admixture of venous and arterial blood, an explanation which has been supported by Meckel and others. Alexander Morison (18) who critically examined some seventy-five cases of congenital heart disease, came to the conclusion that "the main, though not the only factor in the production of cyanosis is the inadequate aid afforded to the circulation by diminished lung functions."

In regard to the second theory, the admixture of venous and arterial bloods, the mingling of these bloods may be most free, and yet no cyanosis be produced. In Breschet's famous case the left arm was supplied by the pulmonary artery, the corresponding subclavian artery arising from it, but the limb was not cyanosed. Further lung functions may also be considerably encroached upon in a case where the mingling of blood is free to take place, and yet no cyanosis appears (19). In a child, aged 9 months, under my care, the right and left auricles practically formed one large chamber, and a patent ductus arteriosus in great measure supplied the descending aorta, yet the addition of extensive

pneumonic consolidation of the lung was not sufficient to curtail its oxygenating functions, for the infant was at no time cyanosed. The parts of the lungs still in action were perfectly healthy.

In another infant of mine, aged 5 months, whose case I have not published before, with transposition of the pulmonary artery and aorta, and a large patent ductus arteriosus, there were the following additional anomalies: A single auricle, with two appendices and a rudimentary membranous septum. There was no trace of a tricuspid valve. The right ventricle was rudimentary, and there was a perforate septum ventriculorum, the size of a crow-quill, leading into it and situated underneath the pulmonary valves. The lungs were quite healthy and pink. The lungs sometimes show an appreciable amount of atelectasis in some infants suffering from congenital malformation of the heart and without the production of cyanosis.

In many cases the explanation is invited, not that the lungs cannot oxygenate properly, but that they are prevented from dealing with a sufficient proportion of the total quantity of venous blood throughout the body by reason of various defects in the pulmonary region, perhaps combined with weakness of the heart muscle.

Cyanosis, therefore, appears to depend in some cases not upon defective aëration from defects in the lungs, but to be due to the conformation of the heart, which by reason of faulty construction and physical weakness is placed at a mechanical disadvantage, and is not adapted to deliver a sufficient quantity of venous blood to the lungs to be aërated.

But this will not explain all cases, for in some the lungs are not healthy and display considerable microscopical alterations. So wide and so tortuous were the thickened lung capillaries in the case of atresia of the pulmonary artery I examined, that those in the alveoli admitted six or more red corpuscles abreast. Changes such as these, permeating as they do the whole of the lung structure, are not conducive to proper aëration. It would appear, then, that diffuse and not localised structural alterations of the lung tissues are favourable to the production of cyanosis. This condition of the lungs alone appears to be sufficient to explain the occurrence of cyanosis in bronchiectasis and chronic emphysema. In the former there is great thickening and dilatation of the alveolar capillaries, and in both diseases there is considerable destruction of them.

Here, then, are two factors in operation—the difficulty of getting the blood to the lungs to be aërated, and the difficulty of aërating the blood when it arrives there, should it so happen that the lungs are not in a position to undertake the operation by reason of their structural defects.

Systemic venous congestion complicates matters; it does not produce them, for it is possible to have a considerable amount of cyanosis without venous congestion. When venous congestion takes place, additional factors come into play which increase the cyanosis, and these are: (a) the formation of enlarged veins and tortuous capillaries throughout the body, and (b) increased viscosity of the blood leading to further retardation of its flow.

Cyanosis, I take it, is due to deficient oxygenation from whatever cause arising, and not necessarily to impaired lung functions.

The explanation for the tardy onset of cyanosis and its origin in sequence to a diffuse inflammation of the lungs, such as broncho-pneumonia, may probably be found in some cases in widespread alterations in the alveolar capillaries. What is required is that attention shall be paid to the lungs of all children dying from congenital morbus cordis. I have examined them microscopically in a few cases, but with negative findings.

In other children perhaps the initial breakdown is in the muscle of the right heart.

#### CLUBBING OF THE FINGERS AND TOES AND OSTEO-ARTHRITIS.

Clubbing of the fingers and toes in congenital heart disease, the so-called Hippocratic fingers, depends almost entirely on congestive swelling and thickening of the soft parts of the terminal phalanges. The con-

nective tissue is increased, and the capillaries are enlarged and increased in number.

The finger-tips are broadened and the nails cyanosed, a different appearance to that shown in chronic osteo-arthropathy, where the nail is domed like a watch glass, curls over the finger-tip, and bears a striking resemblance to a parrot's beak, and is combined with osteo-periostitis of the terminal phalanx. The finger looks like a drumstick, and the nail is pink coloured.

There appears to be two varieties of clubbed fingers; in one there is osteo-periostitis of the terminal phalanges, but in the other this has not yet been demonstrated. Whether there are really two varieties of clubbed fingers, or whether the conditions are different stages of the same process, has not yet been settled.

Sternberg (20) regards the Hippocratic type of clubbed fingers as the commencement of the process, and this is Walter's (21) opinion, who thinks the two conditions are closely allied. He also points out that in the majority of cases of osteo-arthropathy defective blood aëration has been a feature of the case.

Bamberger's and Marie's views are that the bone changes are due to the absorption of poisons generated at the seat of the disease, wherever that may be situated, and it has been shown that about one quarter of the cases have arisen from a variety of affections other than those of the lungs. But these views omit to take into consideration the influence of congestion in the production of the enlargement of the soft parts, which certainly is an important cause in congenital heart malformation, and may be contributory in chronic lung disease.

The toxic effects, however, of the cyanosis in congenital heart disease cannot be overlooked, because clubbing is sometimes seen in these cases without much evidence of congestion.

Béclère (22) looks upon clubbing and osteo-arthropathy as due to congestion and toxæmia. Both clubbing and osteo-periostitis may be confined to one limb, and such conditions have been brought about by the pressure of an aortic aneurysm obstructing its circulation. The explanation advanced for the clubbing and osteo-periostitis is that toxic substances generated at the extremity of the affected limb are retained in the tissues by reason of the venous obstruction.

The youngest child among my cases in which clubbing was obvious was aged 2½ years. It was also stated to be present in one aged 7 months, in whom cyanosis was reported to be slight, but the physical signs were in favour of pulmonary stenosis. Common as is this clubbing of the fingers and toes in congenital heart disease, nevertheless it is a feature of this disease which very often is wanting. It is in pulmonary atresia and stenosis that clubbing most commonly arises, and it is in these conditions that congestion is most frequently observed.

Osteo-arthropathy of the Marie and Bamberger type, as osteo-periostitis of the distal extremities of the long bones as the seat of election with thickening of the carpal and tarsal bones and bulbous enlargement of the terminal phalangeal bones associated with parrot-beak-like nail changes and fingers of drumstick-like appearance is most rare in children. The number of cases reported can be counted on the fingers.

Those cases that have been recorded by Royal Whitman, Davis and Gillet have been associated with chronic lung diseases. Bamberger's case was aged 7 years, and suffered from pulmonary stenosis, congenital cyanosis, and a tuberculous lung. Thorburn's case had mitral disease only. A few cases in association with chronic lung disease have been recorded by Moussous, Gillet, Morzard, Marfan and Miller, in which the characteristic beak-like finger-nails occurring with osteo-periostitis of the terminal phalanges were the sole changes. D. F. M. Miller (23) provides a picture and a radiogram of a child, æt. 8, and contrasts pictures of the fingers in the case with that of a case of congenital heart disease in a child, æt. 7.

Of all the cases recorded that of Royal Whitman (24), in a girl, æt. 8, was the most extensive. There was a deposit of new periosteal bone upon the shafts of the phalanges, upon the metacarpal and metatarsal bones, and upon the lower third of the bones of the lower arm and leg. The knees and ankles and wrists

were enlarged from thickening of the capsules and the soft parts and effusion into the joints. Under the section dealing with the blood changes I have drawn attention to a case of my own in a child, æt. 3 9-12, with cirrhosis of the lung and bronchiectasis where the phalanges and metacarpal bones were thickened.

Cases have been recorded by Weill and Mouriquand (25) and by Variot in congenital heart disease in which to the naked eye the appearances of the finger-tips and toes, the wrists and the insteps at once suggested pulmonary osteo-arthropathy, but when radiograms were made it was found that only the soft parts were involved.

A case of osteo-arthropathy occurring in congenital heart disease in a woman, æt. 21, has been recorded by Batty Shaw and R. Higham Cooper (26). Clubbing of the fingers and toes and cyanosis were well marked, and there was a systolic murmur best heard over the third left interspace. There was no bony increase in the terminal phalanges of the fingers. The lower ends of the tibiae and fibulae were thickened. The bones of the forearms and wrists were slightly swollen, and also the shafts of the metacarpal and phalangeal bones. The osseous index for tubercle was normal.

#### OPHTHALMOSCOPIC APPEARANCES.

*Ophthalmoscopic examination* in cases of marked congestion reveals tortuous retinal blood-vessels of which the veins are very large. The blood in the arteries looks decidedly venous, though they are not quite so dark coloured as the veins. The red reflex, which is of cyanosed appearance, often appears to start from the physiological pit, and the number of vessels on the face of the disc appears to be greatly increased. In children where the cyanosis amounts to but little more than a ruddy bucolic appearance a want of the usual colour contrast between the arteries and veins is quite noticeable. The retinal blood-vessels early display evidences of congestion by enlargement and tortuosity of both arteries and veins. If there be considerable cyanosis retinæ, as sometimes is the case, without the associated appearance of curly retinal vessels, such an ophthalmoscopic finding, although not proof that there is no narrowing of the pulmonary region, nevertheless suggests that the pulmonary tract is either not involved or that right-sided muscular compensation is sufficient to overcome the obstruction.

#### BLOOD CHANGES.

*Blood changes* such as polycythæmia, macrocythæmia, and increased viscosity along with a by no means invariable increase in the hæmoglobin are not uncommon. In one blue child under my care, æt. 2½, with clubbed fingers and toes (27), who had been blue since birth, there was a blood-count of 7,880,000 per c.mm., and the hæmoglobin was 122 per cent. That is the largest number of red cells that I have met with in congenital heart disease. The heart was large, the interventricular and auricular septa defective, and the aorta rose from both ventricles. Hypoplasia of the pulmonary artery and its branches was a marked feature starting at the orifice.

In Planchu and Gardère's (28) infant, a child, aged 6 weeks, in whom cyanosis was slight, but worse on crying, the polycythæmia amounted to 9,000,000 per c.mm. This was with a heart of practically two cavities. Bach (29), in a child, aged 7 weeks, found no less than 11,400,000 per c.mm. There was atresia of the pulmonary artery, a patent ductus arteriosus, cicatricial occlusion of the tricuspid valve, and a rudimentary right ventricle.

Many of the children under my care with polycythæmia have shown a deficiency in the hæmoglobin rather than an increase. In a blue infant, æt. 1, with clubbed fingers and toes and lips, and finger- and toe-tips of purple hue, the blood-count amounted to 5,400,000 per c.mm. red, with a hæmoglobin percentage of 55 only. In an infant with intermittent cyanosis, Variot found intermittent polycythæmia. Weil (30) has shown in two children with morbus cereuleus and congenital morbus cordis increase in the red bone-marrow, and his observations have been confirmed. This increase of red blood-corpuscle producing areas must be viewed as compensatory to the

state of chronic suffocation, which is the normal condition of these patients. Parkes Weber (31) when recently reporting a case of congenital heart disease with polycythæmia, has called attention to the observations by Lorrain Smith and H. L. McKisack on a boy, æt. 12, with chronic cyanosis, who demonstrated not only a relative polycythæmia, but also that the total amount of blood in the body was far beyond the normal standard—nearly double. In Weber's case, a youth, æt. 22, compensatory polycythæmia was extreme, the blood-count amounting to 10,300,000 per c.mm.

The most intense polycythæmia that I have met with in a child occurred in a case (32) of cirrhosis and bronchiectasis of the lung in a boy, æt. 3 9/12. He was very blue, clubbing of the fingers and toes was a marked feature, and the phalanges of the hands and the metacarpal bones appeared to be thickened. (33) There was extension of the cardiac dulness to the right. A blood-count gave 8,270,000 red corpuscles per c.mm.

Among other symptoms of congenital morbus cordis respiratory acceleration is the rule, though it does not always occur when the child is at rest. In some cardiac pain is a feature. In a case reported by Hand, junior (34), in a case of pulmonary atresia, attacks of dyspnoea were associated with heart pain, an angina pectoris, and during the attacks the respirations were slow and laboured. The pulse is often accelerated. In only one form of malformation is it slowed, and that happens sometimes in pulmonary stenosis. The temperature is frequently subnormal. Growth and nutrition may both be faulty, and infantilism sometimes results.

NOTE (Editorial).—Considerations of space prevent us publishing the whole of this valuable lecture. In the remaining portion the author deals exhaustively with congenital heart murmurs, defects in the interauricular septum, stenosis and atresia of the pulmonary region, ductus arteriosus, co-actation of the aorta, congenital aortic stenosis and aortitis, hypoplasia of the aorta, the auriculo-ventricular valves, hypertrophy, and cardiac displacements. A full literature and many illustrative cases are appended.

### THE PSYCHIC TREATMENT OF ALCOHOLIC INTEMPERANCE, BASED ON A PERSONAL EXPERIENCE WITH 1,000 CASES. (a)

By JOHN D. QUACKENBOS, A.M., M.D.,

Member of the London Society for Psychological Research; Fellow of the New York Academy of Medicine, &c.

I HAVE been requested to discuss the treatment of the drink habit by hypnotic suggestion; and I shall consider the question with reference especially to the *technique*, the class of cases that are amenable, time limits of treatment with general results, and permanency of cure.

The phenomena of suggestion are explicable on the theory of simultaneous self-manifestation in two distinct worlds of consciousness—a theory now generally accepted by psychologists. These are distinguished as the objective or supraliminal, the world of every day waking life; and the subjective or subliminal, the world of sleep, in which the immaterial part of the man employs itself without corporeal restraint. The subliminal, superior, or better self—the *pneuma* or spirit of the New Testament—is that deathless entity that constitutes the true or "inner man," a vast spiritual organism, the created copy of God, and as such measurably endowed with divine attributes and powers. The objective self is an expression, imperfect and partial at its best, of this subliminal through "the flesh," that is, organs of body and faculties of mind. Now the possibilities of a psycho-dynamic control of the objective life by this higher self are practically boundless, and the whole purpose of hypno-suggestion is the establishment of such control, either where it has become relaxed or in fields where it has not before been exercised. So long as the subpersonal mind quickens sound organs, all defects or irregularities in the fulfilment of their functions may be remedied by assumption of the natural psycho-physical regulation, and so diseases

(a) Delivered at Washington D.C., March 8th, 1909.

that are not organic are curable by appeal to the subliminal self which orders organic life. Still further, all attitudes of the objective mind—its trends of thought, opinions, beliefs, desires, propensities, tendencies, emotions, and passions—are controllable and alterable by this higher human personality, exclusively along lines that are moral and true. And suggestion is nothing but a straightforward, heartfelt, forceful appeal to this personality, the source of spiritual energy in man's being. It is of the nature of creative communication, a calling forth into overpowering action of the God part of man—action that carries all before it in the earth-life—all tendency to deviation from the normal type, physical, intellectual, moral—even the objective will itself, iron though it seem to be.

Man, then, in his higher personality, is adequate to the extirpation from his objective nature of any abnormal craving or passion, like the craze for intoxicants. The latter is singularly responsive to treatment by suggestion. In fact, many of the popular drink cures are in reality mere suggestion cures, there being no peculiar virtue in the drugs administered, as there is no specific for the cure of drunkenness. The temporary success occasionally met with is due entirely to suggestive action on a susceptible patient anxious for relief. The fascination of mystery plays its part in the process, and thus the charlatan differs from the regular physician who operates on the psychic centres with the full consent and knowledge of the patient.

The notable increase in the consumption of stimulants, especially among the upper classes, estimated at ten per cent., during the last decade in the case of men, and a much larger percentage in that of women, is inviting anxious attention to a means of treating the victims of alcoholic inebriety, for which so much has been claimed in this country and abroad. Upward of one billion dollars are spent annually in the United States for intoxicating drinks, and another billion for the relief of the destitution, the punishment of the crime, and the care of the physical and mental diseases that result directly from the drink habit. Especially alarming is the growth of the practice among our women. The punch-bowl figures at all functions, and proud-pied matrons dip freely therein, ten drinking to-day where one drank a dozen years ago. School misses and college girls are conspicuous among the throng. Such has become the vogue; and, worse than this, girls in their teens see no impropriety in drinking publicly with men companions.

Not a few women have lapsed into the drink habit from the use of patent medicines containing large percentages of alcohol. Many a clergyman can date his downfall from his first dose of Jamaica ginger. The step from "disguised boozes" (upon which \$75,000,000 are annually expended) to whiskey, their main constituent, is more than easy. Even school-children are becoming beer and wine drinkers, especially those of foreign parentage, and the increasing prevalence of this habit is leading to a mental sluggishness, if not defect, among the pupils of the public schools that is attracting the attention of educators and philanthropists. In few, the prevalent wholesale addiction to the use of alcoholic stimulants—with its accompanying degenerations of kidney, brain, heart, liver, stomach, and arteries; its pernicious influence in the causation of pneumonia and tuberculosis; its direct action in diminishing nervous resistance and so increasing the mortality rate in the case of all diseases; the part it plays in the induction of insanity, one-third of all mental affections being due to its abuse; and its tendency to transmit to offspring not only epilepsy and mental defect, but marked degeneracy and criminal propensity, is assuming proportions so appalling that it may justly be regarded as perhaps the greatest existing menace to the stability of American institutions.

Moreover, the rank and file of the drinking population are swallowing a poison far deadlier and more rapid in its action than genuine ethyl alcohol. This fact is ignored by the temperance reformer and often by the physician. The consumption being greatly in excess of the ability of the brewers and distillers to

produce wholesome beverages, notorious adulterations are resorted to. About fifty million barrels of malt liquors represent the yearly output of the United States. Much of this, to meet the demands of trade, is sold when new and imperfectly fermented, and a great deal of sickness is the result. Besides, the beer drinker has to run the gauntlet of various preservatives, especially formalin, with its destructive action on all the organs; of artificial bitters like salicin, picric acid, quassia, strychnia, and aloes; even of arsenic derived from sulphuric acid made from arsenical pyrites, and used in the process of manufacture to convert the starch into glucose.

Intoxicating liquors are as liable to adulteration; but it must be conceded that it is the raw alcohol as well as the admixtures that causes the chronic catarrh of the stomach, the Bright's disease, the arteriosclerosis, the palsies and ataxias, the nervous bankruptcy, and the moral degradation of the dram drinker. Good rum as well as bad rum will, when used to excess, gradually convert the different organs and tissues of the body into specimens of degeneration and disease. Bad rum is more prompt in its action, and almost all the rum that is retailed is bad, the alcohol being made from corn, roots, refuse molasses, and even sawdust converted by acids into a fermentable sugar. It is the practice of the liquor dealer to stock his cellar with casks of crude grain or potato spirit liberally tintured with fusel or grain oil, an irritant poison. He then provides himself with a full line of laboratory-made essences—brandy essence (consisting of oil of grapes, acetic ether, allspice tincture, and alcohol), rum essence (composed of butyric ether, acetic ether, vanilla tincture, essence of violets, and ninety parts alcohol), gin essence, hot-drop essence, whiskey essence, etc., and in accordance with the instructions of a hand-book furnished by the essence manufacturer proceeds to make from the same barrel of crude grain spirits, by the addition of the prescribed quantity of the several essences, what he advertises over his bar as pure liquors. The same barrel gives birth to Bourbon, rye, wheat whiskey, malt whiskey, Scotch and Irish whiskey, Jamaica and Medford rum, Schiedam-schnapps and Old Tom, cherry, peach, apple, blackberry, and Cognac brandy. The cost of the amount of essence required to manufacture in this way 120 gallons of Cognac, 160 gallons of gin, 40 gallons of any kind of rum, and 160 gallons of any kind of whiskey, varies from \$3 to \$4. Such are the cheap artificial imitations of distilled spirits, the frightful compounds of fusel oil and whiskey essence the saloon-keeper palms off with impunity upon the *habitués* of his cabaret. Properly matured ethyl alcohol or unadulterated whiskey, itself a protoplasmic poison, is hardly obtainable in an American bar-room. Of every hundred drinks sold in the United States as whiskey to-day, only one is really whiskey; but so clever is the counterfeit that club connoisseurs have failed to detect it. Amylic alcohol, or the common whiskey of trade (and it matters not whether it is dispensed by a bishop or a bravo), is the "death's river" setting in resistless current toward murder, robbery, misuse of women, paresis, and the asylum. Whatever moral, social, or legislative measures may eventually be adopted looking to the suppression of the drink habit, we are in urgent need of power to restrain in appropriate institutions the habitual drinker of these poisonous spirits, who is, under the present conditions, a danger to himself, a curse to his family, and a nuisance to the State.

The following case of a gentleman who drank whiskey is representative both of the alcoholic disease and its causation, and of the method pursued:—

Four years ago Mr. A., who had vainly resorted to the popular drink cures, was induced by his friends to make trial of psychic treatment. Beginning as a college boy to carouse with his mates, engaging in contests to see who could drink the most beer in the shortest time, he passed successively through the stages of occasional use for convivial reasons, frequent indulgence to brace him for task or pastime, periodical paroxysms of alcoholic debauchery, until at forty he found himself a continuous drinker impelled by an

irresistible and insatiable craving, with marked stigmata of degeneration and a growing incapacity for professional duty. His wife and daughters, for years subjected to constant humiliation at his hands, had come to feel the pinch of want, and smarted under the construction placed upon his actions by a merciless society. Affection had died in his heart and with it both self-respect and religious sense. In such a case at least a year is usually required of forced feeding and restricted activity to repair the damaged brain cells and so restore the patient to normal efficiency. But within a week the mental attitude may be permanently changed and the craving for stimulants obliterated, without experience of the nervous exhaustion and unrest that usually accompany discontinuance of the habit. Since his first *séance* (now six years ago) Mr. A. has experienced no desire for alcohol. The suggestion was given that he would no longer deceive himself with the thought that he could safely take one drink and then stop, but that it was impossible for him ever to want a drink or ever to take a drink for any conceivable reason. He has abstained, not through conscious effort, but spontaneously because of an ingrained disinclination to drink, conditioned by subpersonal control. In this instance it was further necessary to forbid the use of tobacco, the inhalation of which in the form of smoke, by depressing the nerve centres and thus creating an imperious demand for its antidote (whiskey), explains seventy-five per cent. of all the cases of methomania. The chain of cause and effect was broken at a blow. The patient neither smokes nor drinks. And he has made amends for the suffering he inflicted on his family by exalted action meriting their respect and love.

In contrast with the foregoing is the following extreme case of chronic poisoning by adulterated liquors excessively indulged in between the ages of sixteen and thirty-seven. Every Saturday night W. B. drank to intoxication, and committed other excesses that fill his mind with remorse, so that his condition borders on theomania. He imagines the people riding on the car with him know all that he has done, and that the children on the street are cognisant of his misdoings, and are calling him names significant thereof. He is afraid of everything. He suffers from hallucinations of vision. A woman with a baby carriage is forever following him. He sees green flashes in the dark, and men going through various motions. Flies attend him everywhere, hovering about, showing him how to use his tools, etc. He does not know the difference between a real and an imaginary fly, and continually shoos the latter variety. Three separate voices talk to him, coming up the dumb-waiter shaft or speaking through the window. They never desist even while he is at work, and at times seem so real that he looks around to see who is speaking. One voice will keep repeating some message, laying stress principally on his sins. If he is reading a paper it reads ahead of him. Three years ago his mind gave way, and he took a flat-iron and went upstairs to kill a man who was calling him vile names, the man being perfectly innocent. He rallied from this seizure, but returning to his fusel oil he has become subject to melancholy spells and to attacks of amnesia, so that he loses his sense of identity for days at a time.

This is not a common case of three sheets in the wind, but rather of a noble brought to ninetence through incurable degeneration of the brain. There is no hope for such a victim in mental theriology.

By means of the enlightened employment of hypno-suggestion, the subliminal self of the ordinary inebriate may be placed in control. So it is no longer a valid argument for a man to hold that he gets drunk because he cannot help it. Statistics show that the treatment of alcoholic subjects by suggestion (in this country and abroad) gives at least seventy-five per cent. of radical cures. All other known methods have never given more than thirty per cent.

Dipsomaniacs, as a rule, are easy subjects, in that they yield readily to the hypnotic influence, and accept unconditionally the suggestions communicated by the operator. Regular drinkers may be dealt with whenever they can be induced to be sober. Periodic

drinkers should be treated just before the close of the cycle of sobriety. Regularly recurring debauches have periods of varying length, the longest in my experience being three years; and I have satisfied myself that in many instances a relationship exists between the abuse of tobacco and the on-coming of the irresistible thirst, the depressing effects of the nicotine instinctively suggesting recourse to the antidote. Periodic drink-storms are usually forecast by significant indications well known to the family and friends of the victim—irritability of temper, unreasonable suspicion, so described "cranky spells," abnormal restlessness, unaccountable depression. Immediately upon the appearance of these symptoms the patient should be treated by suggestion, before opportunity is given for indulgence of the craving. Such a subject frequently recognises his danger and sincerely wishes to be cured. He is tactfully conducted into the subliminal sphere, and then assured that, in accordance with his own desire and decree, he has lost all craving for beer, wine, whiskey; that alcohol in any form is repugnant to him, and, as a safeguard, that he cannot swallow it, cannot carry the containing glass to his lips. The society of low companions is tabooed; the pleasures associated with drink and the glamour of the bar-room are pictured as meretricious, and placed in vivid antithesis to the chaste delights of home life. The physical, mental, moral, and economic bankruptcy that accompanies dipsomania, is held up before the view of the sleeper, and he is forced to the conviction that begotten of this apprehension has come into his soul an abhorrence for drink and all that it stands for. He realises the presence of efficiency within him adequate to the enforcement of radical abstinence as the principle of his life; and he is rendered insensible for the future to any such combination of passion and allurements as has usually constituted temptation. So he is led instantaneously to scorn recourse to alcoholic stimulants, or to extrinsic exaltation of any kind, either for convivial reasons or in time of depression, misfortune, or sorrow, and to depend exclusively, under any mental or physical strain, on the units of energy legitimately manufactured out of nutritious food, non-intoxicating drinks, air, exercise, and sleep. The subpersonal mind is then directed to the vocation or the avocations, or both, as circumstances suggest, and a career of wholesome activities and satisfactory success is imaged as the legitimate result of the abandonment of the compromising habit.

Hypno-suggestion here is clearly of the nature of inspiration. It is a summoning into control of the true man. For the patient freely expresses his best self post-hypnotically, without effort, from a plane above that of the will—the plane of apprehension and spontaneous command along lines of thought and action that are worthy and wholesome. And inspiration, to be efficacious, cannot be mere lip work or rote-lesson. It implies a belief in the suggestions offered, an eloquent and incisive manner born of the courage of conviction; in short, it is a transfusion of personality. Perfunctory speeches are of no avail, for the mind of the subject is endowed with supernormal insight, at once detects the disingenuous, and declines impulsion at the hands of an insincere or lukewarm operator.

A *sine qua non* of success is the consent of the patient, an honest desire on his part to reform. Habitual drinkers, those who "soak," as Goldsmith described it, do not, as a rule, wish to be cured. They enjoy indulgence in alcoholic beverages and the false pleasures that attend it; and about ninety per cent. of them, women as well as men, resent the approaches of those who desire to save them. Sometimes, when no other form of appeal is effective, they may be frightened into a realisation of the fact that constant use of alcoholic stimulants will result in organic changes in the liver, kidneys, and brain, or by lowering the general powers of resistance and at the same time irritating the bronchial tubes and the lungs, through which the alcohol is in part eliminated, markedly predisposes to pneumonia and tuberculous consumption. In fact, immoderate drinkers may, in sober intervals, be made to realise, not only that they

are physically depraved, but intellectually degenerated as to the faculties of memory, attention, concentration, judgment, and that they are deficient in business tact and in the general address essential to success. Once apprised of their enervated mental condition, they are overcome with remorse and honestly desire to correct the habit. Under these circumstances it is comparatively easy to persuade a patient to accept treatment, and a rescue may be effected in a week's time. To quote a Hindu proverb, "In the awful silence that follows the storm, not in the silence before it, we should search for the budding flower."

No reference is here intended to dipsomania as a true circular insanity, characterised by irresistibly compelling paroxysms of thirst and accompanied with uncontrollable nervous and mental excitement. It has been truthfully said that a sufferer from this disease is insane before he begins to drink, and would continue to be insane during his period if whisky were unobtainable. Thus there may be dipsomaniacs who have never tasted alcohol. The alcohol is a secondary factor. In other words a man may drink because he is crazy, or be crazy because he drinks, or both; and a physician who grapples with the combination has a veritable wolf by the ears.

It is not claimed that the tendency to relapse is absolutely obliterated by suggestion. The cure may or may not be permanent, as is the case with rheumatism, quinsy, bronchitis, intermittent fever with its distinct germ and distinct specific. No physician is asked to guarantee a patient against a recurrence of tonsillitis, especially when the patient deliberately exposes himself to the appropriate conditions of a relapse. More cannot be expected of the physician suggestionist, who is not a miracle-monger. The utmost he can do in a prophylactic line is to reject all compromises in his treatment, suggest total abstinence, forbid exposure to temptation, and render insensible to the psychology of the saloon. Experience proves that it is always better to deal in drink-habit cases with the nearest of kin rather than directly with the patient, who naturally over-estimates his power of resistance and is singularly impatient of restraint. Courting a conflict with the demon of drink, as many do, is playing with fire.

Various reasons are advanced by backsliders to explain their relapses, and some of them are most trivial, as the death of a favourite dog, dull times, inharmonious in the family. Some drink when they feel best, others when they feel worst, other some because they deem it a satisfaction to "go off on a tear and tank up." One man used the argument that he had gone sober so long he was justified in a debauch. A lady admitted her motive to be the delight she experienced in drinking with her admirers and listening to their flattery and compliments. Another lady, with a much greater show of reason, explained her periodicals as due to the cumulative brain fog resulting from a miscellany of little worries. Here, as in many similar cases, alcohol serves to obscure fatigue or cell exhaustion, which, if so treated, must end in neurasthenia or irreparable brain damage.

Many drink to dispel the blues, to induce sleep, to rouse courage or confidence. A very intelligent inventor offered four reasons for indulgence, viz., requirement of the system in consequence of physical depression, sociability, business necessity, and cold blood or "pure cussedness." Sometimes the drinker has no object in view, but seems to be actuated by a sense of obligation to a long-standing habit, periodical conformity to which is fraught with discomfort and misery. The psychology of this latter mental state is illustrated by the following experience of a friend, who, a summer or two ago, met a former acquaintance on the public highway, trudging along to a near-by village. "Where are you bound for, Uncle Billy?" he inquired, in a spirit of neighbourly bonhomie. "I am going into Johnstown," was the reply, "to get drunk, and O Lord! how I dread it!"

I have already stated that seventy-five per cent. of inebriates are abusers of tobacco, and that in this latter abuse is to be found the proximate cause of much alcoholic intemperance. The real danger to the smoker consists in the habit of inhalation, whereby

the volatilised poisons of tobacco are brought into immediate contact with many hundred square feet of vascular air sac walls in the lungs, and are thus promptly and fully absorbed, to be diffused into the blood and carried on their fatal errand to the several organs of the body. Young subjects immediately learn to inhale. They are, moreover, markedly susceptible to the influence of tobacco poisons. Gravest of all the resulting evils is the lessening or complete loss of moral sensibility, with a conspicuous tendency to falsehood and theft. The moral propensities are eventually destroyed because of the destruction of those elements of the brain cells through which moral force is expressed. The victim degenerates into an unmanly, unprincipled, irresponsible doddie-poll, in splendid fettle for the penitentiary or the mad-house.

The circulation through the brain of tobacco smoke poisons and alcohol, destroys the capacity for expressing through that brain earnestness and sincerity in efforts to reform. Fortunately, the damage done to the cells is reparable by the discontinuance of the toxins and the judicious administration of nourishment, general and specific. While hypnotic suggestion may regulate a disturbed metabolism in the nerve organs, or check atrophic changes in cell protoplasm, it cannot be expected to repair lesions in the blood-vessel sheaths, or suddenly atone for the results of an exaggerated destructive metamorphosis in the nerve-cell bodies. Therefore, in my treatment, alcohol is immediately withdrawn; stimulating liquid food is given every two hours for a day or two; and the phospho-glycerates, representing true brain aliment, are administered for six months to a year, with a view to refining the quality and increasing the quantity of the lecithin through which resolution and general manliness are expressed. In the insanity of extravagant drinking, coupled with chronic nicotine poisoning, suggestive treatment may sometimes be delayed with advantage until after the compulsory reduction or withdrawal of the artificial stimulant. Patients who, to rid themselves temporarily of the importunity of relatives, accept an institutional life, with mental reservation as to their habits at the termination of the period of treatment, are proper subjects for suggestion while in sanatorium. "The tongue has taken the oath, but the mind is unsworn." Under such circumstances, with the craving in lull, the subliminal self may be successfully impressed.

The success of the treatment outlined above bears a distinct relation to the amount of injury already inflicted upon the brain cells and the accompanying mental deterioration. Its advantage consists in the rapidity of restoration to self-control without the necessity for effect of will, without the physical discomfort of suffering that usually attends abandonment of the habit, and, most conspicuously, without the breaking of family ties and the enforced absence from professional or business duties that are implied in sanatorium treatment.

The views here advanced are based upon an experience with some thousand cases of alcoholic intemperance extending over a period of ten years. Of these, between eighty and ninety per cent. have been restored. Of the remaining fifteen per cent. a number cannot be traced; a number indifferently submitted to one or two treatments out of deference to the entreaties of friends, and hence there was no objective self-surrender; a few had become paretic before the treatment was begun; a small fraction were society women, who, in my experience, are almost without the pale of hope. In no other condition that I have been called upon to treat by suggestion am I so unreservedly warranted in saying to the sufferer, "If you sincerely desire to be cured of this malady, and will carry out my instructions faithfully for a year, you can be cured beyond a peradventure."

---

DR. F. W. PAVY, F.R.S., who represented the British Government at the International Medical Congress, Budapest, last week, presented the official invitation to "meet again" at London in 1913, which was cordially accepted.

## HEREDITARY SUDDEN DEATH.

By A. GILBERT, M.D.,

Professor at the Faculty of Medicine, Paris

AND

A. BAUDOUIN, M.D.,

Ex-Interne of the Hospitals, Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

WE sometimes meet with instances of sudden death in persons who may or may not have presented premonitory attacks of syncope. We must not look for an explanation of their untimely end in a non-existing heart disease but on an hereditary predisposition, which may be elicited by aetiological investigation. In these cases there is a sort of diathesis, the diathesis of sudden death, which is the subject of this article.

We have not been able to discover any reference to this morbid type in medical literature. Text-books of pathology, it is true, occasionally mention the hereditary nature of certain forms of syncope. As Merklen remarks "with respect to the tendency to syncope and its consequences it is important not to lose sight of individual predisposition and the state of the heart. Some people faint or fall into syncope on the most trivial thing; an emotion, a particular odour, the sight of blood, trifling pain, intestinal disturbance, etc. This special sensitiveness is innate, often hereditary, and manifests itself from childhood. These, however, are cases of simple faintness, which is something quite distinct from fatal syncope.

Even those who have devoted special attention to heredity have nothing to say with reference to hereditary sudden death, and text-books on legal medicine are mute on the subject. Alone Dr. Vibert mentions a case, referred to later, of two sudden deaths, in father and son, and even he does not seem to have drawn any conclusion from this isolated instance.

Nevertheless, in spite of the absence of exact data on the subject, medical examiners for life insurance seem to have a glimmering idea of the kind, since the sudden death of an ancestor is always regarded by them as a sufficient reason for demanding an extra premium. The public, too, seem to have vague floating ideas of the kind, and our object is to establish, as far as possible, the degree of truth comprised therein.

We have had under observation six families from this point of view, five in private practice and only one in hospital. The facts came to our knowledge, so to speak, of themselves, in the course of a few months, without any investigation on our part. It may, therefore, be inferred that this morbid state is far from rare, indeed, that it is tolerably frequent. Its importance is enhanced by its bearings on hygiene and legal medicine.

Sex appears to possess a certain influence. Our inquiry bore on fourteen persons who had died suddenly, and of this number eleven were men and only three women. Although the limited number of our cases does not warrant any firm conclusion, we hold that this special predilection for the male sex is worthy of note because the tendency to faintness is far more marked in women.

The age at which the fatal syncope took place is very variable, oscillating between twenty and sixty-two years of age. Speaking generally, the incidence of sudden death is earlier in the descendant than in the ancestor by whom the diathesis was transmitted. This is on a par with what is observed in other morbid states transmissible by heredity, diabetes for instance. In cases in which the difference of age is very marked we may invoke bilateral heredity as in one of our own cases. The paternal grandmother of B. died suddenly at the age of 52 on his return from a watering place; B.'s mother is still living but has twice had syncope attacks and turns faint whenever she sits in a train with her back to the engine. Quite recently, after abdominal hysterectomy for fibroid, she was suddenly seized with grave asystole which yielded only to energetic treatment. B. died suddenly at 27 years of age after a series of syncope attacks. Death at this early age was attributed to his father and grandmother. We hold that the influence of maternal

heredity may also be invoked in this instance, especially as the syncope tendency is well marked in his mother.

The underlying cause of the diathesis is heredity. In most of our cases this can only be traced one degree, from father to son. In two cases it was traced back two degrees. The first was the patient whose case has just been related, the second was that of a woman, æt. 40, whose paternal grandmother died suddenly at 60. Her father succumbed in like manner at 62 after his day's work, and the patient herself presented a well-marked tendency to fainting attacks. In this instance the tendency reached to three generations. No doubt if one could go further back other antecedents of the kind would be discovered. We are inclined to think that such would be the case although *a priori*, one might argue that the existence of this diathesis would lead to the early extinction of the family. Such inquiries present innumerable difficulties. To begin with, the subject of inquiry dates back to ancient history, the incidents of the kind may have been forgotten by the descendants, moreover, families in which sudden death occurs are anxious to keep the matter secret.

Independently of heredity our investigations brought to light many and various predisposing causes. Some of them, supervening only a short time before the final syncope played the part of accidental causes. These indeed are anything but constant, for in several instances nothing whatever could be discovered. In one, a person free, as far as was known, from disease and previously in excellent health, fell dead when out walking; similarly in the case of a man who all at once felt queer, went to bed, asked for something hot, and expired forthwith.

Then, too, the accidental cause is often so trifling that it cannot account for the brutal end, as in the case of a man suffering from physical and mental overwork who had contracted a mild attack of influenza which kept him at home. His state inspired so little anxiety that he spent the evening preceding the fatal syncope playing cards merrily with his friends.

We do, however, meet with more serious causes, though always quite ordinary, of a kind that would not be productive of any serious trouble in the average healthy man. Independently of syncope heredity we meet with alcoholic habits, attacks of gout, and addiction to narcotics, especially morphine. In two cases there was a history of mild syphilis under proper treatment. Professor Fournier has drawn attention to the frequency of sudden death in syphilitic subjects, but in our opinion the syphilis had nothing to do with death in these two instances. When fatal syncope is due to syphilis it is generally consequent upon chronic aortic lesions. In these cases the most careful auscultation had failed to reveal anything abnormal and in one of them the patient had had six severe attacks of syncope before the terminal one. These had taken place at long intervals, from infancy upwards, and five of them occurred prior to his contracting syphilis.

Some insignificant surgical operation, in a person with this morbid heredity, precipitated death in a case reported by Dr. Vibert. A child, of twelve years of age, died suddenly after cauterisation of pharyngeal vegetations. The child's father had died under very similar circumstances. He was stung by three or four wasps, managed to reach home with the greatest difficulty, and died almost at once.

So far we have only met with commonplace precipitating causes, and as in all our cases the existence of syncope heredity was clearly established, we are justified in according it a foremost place. We have, however, occasionally come across instances in which the accidental cause was, on the contrary, so manifest that it seemed to dispense with the necessity for looking further, but even in these, as the morbid heredity was quite clear, it may be held to have played a part. Obviously it is not everything, but even so it may have contributed to the result.

One was a case of sudden death during an attack of pleurisy. A young woman, æt. 20, had an attack of pleurisy, *à frigore*, in January, 1908.

Physical examination revealed a moderate amount of effusion, not displacing any organ, and the heart in particular appeared quite healthy. In the course of a few days, as the fluid had somewhat increased in amount the desirability of puncture was discussed when all at once the patient, after an attempt to sit up in bed, fell back dead.

Observations of this kind are plentiful. In some, death was rapid but not sudden, and was ushered in by asphyxial symptoms, and at the autopsy cardiac thrombosis or pulmonary embolism was found. In others, death was quite sudden and nothing could be found post-mortem.

Professor Dieulafoy observes that in these cases the pleuritic effusion is more frequently on the right side, adding that there is a difficulty in explaining death. In the case of the young woman just referred to, it is open to question whether heredity may not be incriminated at any rate on one side. Her father, a doctor, complained all his life of oppression and palpitation. He is still living, but displays a tendency to faint on the slightest effort.

The second case is one of fatal syncope in a man, æt. 39, after the administration of a moderate dose of cocaine in view of an operation for cataract. The operation took place at 8 p.m. Everything went off smoothly and the patient passed a good night, but at 5 a.m. he suddenly expired. We can hardly incriminate the cocaine since death did not occur until nine hours later. His father had also died suddenly at the age of 49.

In all we find traces of the same diathesis, and this may help us to explain many cases of death under chloroform. Patients suffering from very mild attacks of typhoid fever sometimes die quite unexpectedly, and here again it would be well to inquire into the family history.

One of the most interesting points, possibly the most important of all, is the supervention of periodical attacks of syncope before the fatal one. This was the case in two of our patients. In one, according to his mother's story, he had had six such attacks before the last, and it is highly probable that he had had others of which she knew nothing. The first occurred at five years of age, the second at fourteen, both while travelling by rail. The third and fourth occurred at school, and the second of these was particularly severe and prolonged, in fact he was thought to be dead. He had the fifth while serving in the army, and the sixth in December, 1907, one month before the final attack in January, 1908. This sequence is very characteristic, and we cannot insist too strongly on the gravity of these disturbances, this gravity, indeed, distinguishes them from mere attacks of faintness.

In other cases the syncopal tendency was less marked, and in some it is distinctly stated that none had ever occurred.

In these cases, apart from the morbid heredity and the habitual pallor of the case sometimes noted, there is little to note. Death may not be preceded by any premonitory signs, one patient fell dead in the street, another when out walking, the body of a third was found in bed with the bedclothes undisturbed and a calm look on his face. Sometimes, however, the patient experiences a vague malaise, he groans, asks for something to drink, turns and twists himself about, but in all death is sudden, not the death that follows cerebral hæmorrhage but death due to arrest of the heart.

Now to what does this diathesis correspond? What is the *primum movens* of this sudden arrest of the heart? Of this we know absolutely nothing and we are reduced to hypotheses, which we will now briefly discuss.

Is it due to changes in the cardiac muscle fibre? We are beginning to grasp the fact that the myocardium is not a constant factor, that there is such a thing as congenital or hereditary weakness of the heart muscle. Whether sudden death is to be attributed to this cause is another matter. We might just as reasonably incriminate the intra-cardiac nervous system, the pneumogastric or the medulla. This is for the time being an insoluble problem, indeed, so far, we are

not even in a position to explain the mechanism of death from heart failure in the course of acute infectious diseases.

We have already insisted on the necessity for distinguishing between the tendency to grave syncope associated with this predisposition and mere faintness. There may be intermediate states, but in typical cases they are easy to differentiate, and it is important that this should be done in view of the difference in the prognosis. Benign in one case the prognosis may be very grave in another, a fact of which the patients themselves are often aware. We have met with patients whose life was one long anguish with the terror of an untimely end ever before their eyes. One patient who had lost both his father and his brother from sudden death lives on in a state of abject apprehension. "I have my father's heart," said one woman, and I shall die like he did."

This morbid state hardly admits of treatment beyond strict hygiene. It is nevertheless very useful to be aware of its existence, for in practice this knowledge may enable us to foresee or explain the possibility of sudden death, and, on the other hand, it shares the interest that attaches to everything bearing on the great problem of heredity.

## OUT-PATIENTS' ROOM.

### ROYAL FREE HOSPITAL.

#### *A Case of Simple Ganglion.*

By WILLMOTT EVANS, F.R.C.S.

MR. WILLMOTT EVANS had a patient, a young woman, æt. 24, on the back of whose left hand was a semi-globular swelling measuring about an inch in diameter. It was tense, and fluctuation could be detected. It had existed some six months, and it had followed a strain. It was evidently an ordinary case of simple ganglion. Mr. Evans treated it as follows:—The skin over it was washed with a solution of carbolic acid, one in thirty, and the surface was then frozen by an ethyl chloride spray. The point of a tenotome was passed into the swelling, and it was turned in different directions so as to penetrate into every part of the swelling, the handle of the tenotome being kept parallel to the back of the hand. When the tenotome was withdrawn pressure on the ganglion caused the exudation of a clear, jelly-like substance. A small pad of gauze was placed on the site of the swelling, and a bandage applied. Mr. Evans said there was seldom any difficulty in the diagnosis of these cases, though it was important to bear in mind that some of these ganglia were tuberculous in origin, and they required different treatment. Compound ganglia were nearly always tuberculous, but it was quite exceptional for a simple ganglion to be tuberculous.

The mode of origin of these simple ganglia was not only of interest, but it also had some therapeutic importance. The older explanation and one still to be found in many text-books was that a simple ganglion arose as a hernial protrusion from a tendon sheath, and that later the communication between the protruded portion and the general cavity of the tendon sheath became blocked. In opposition to this explanation, it might be pointed out that the stage where the cavity of the ganglion still communicated with the cavity of the tendon sheath had not been seen, and, further, that the contents of the ganglion did not consist of ordinary synovial fluid, but contained a much larger proportion of mucoid material. For these reasons he did not accept this explanation. The other explanation was that put forward by Sir James Paget. He suggested that the condition was produced by a mucoid degeneration occurring in one or more of the fringes of the synovial tendon sheath. In favour of this explanation there was the fact that synovial fringes were prone to undergo mucoid degeneration, and also that it was not unusual, in fact, it was almost the rule, that a simple ganglion was loculated, that is, it consisted not of a single cavity, but of a number of separate, non-communicating cavities. It was impossible to explain this fact on the hernial theory, but

it was easily explicable on the theory of metastoid degeneration occurring in several foci. The treatment, however, was of the most importance. The oldest method of treatment was to endeavour to burst the sac by means of external violence. The wrist was forcibly flexed, so as to make the ganglion as tense as possible, then steady, firm pressure was applied, or what was more effective, a sudden blow was given with a heavy object, such as a large book. The amount of force required was sometimes great, especially in the more chronic cases in which the wall of the ganglion had become thick. When the ganglion wall gave way the contents were poured out into the subcutaneous tissue and were absorbed by the lymphatics. Mr. Evans had on one occasion seen a rather sharp attack of a localised cellulitis follow the treatment by rupture; but the cellulitis had disappeared in three or four days with cooling lotions, and probably it was due to some chemical irritant contained in the ganglion and not to any microbic infection. The most convenient treatment Mr. Evans considered to be that employed in the case shown, namely, evacuation of the contents through the opening made by a fine knife, after freezing the part to prevent pain. By this method it was possible to break down the trabeculae which divided the cavity into a number of separate spaces. The operation was rapid and harmless, and it caused less pain than the method by forcible rupture. In some cases where recurrence had occurred, or where there was any reason for thinking that the ganglion was tuberculous, the best treatment was excision. This was a simple operation, and though a general anaesthetic was convenient, it was by no means necessary, for local anaesthesia was quite sufficient. This was best attained by subcutaneous injection of a weak solution of any of the ordinary local anaesthetics, beta-eucain being probably the best, and only a small incision was required. The X-rays were capable of causing the disappearance of simple ganglia, whether tuberculous or not, but great care was required to prevent a harmful action of the rays on the skin. A word might be said on the question of recurrence of a ganglion after apparent cure. In some cases it was a true recurrence, the same sac being refilled with fluid, but in many cases it was certainly a further formation of ganglia in the neighbourhood of the one which had been already cured.

## OPERATING THEATRES.

### GUY'S HOSPITAL.

**TREATMENT OF VICIOUS VOMITING AFTER GASTRO-JEJUNOSTOMY.**—MR. ROWLANDS operated on a young woman who had formerly been a nurse in America, and had been operated upon by a distinguished surgeon at Cleveland for a large gastric ulcer in the pre-pyloric region. Very soon after this operation vicious vomiting set in, although the operation was successful in abating the symptoms of gastric ulcer. The patient had been referred to Mr. Rowlands for operation by Drs. Morton Palmer and Hertz. The patient used to vomit a large quantity of bile-stained material nearly every day, and she had lost about a stone in weight. Dr. Hertz had examined her by his method of X-rays and bismuth, which showed that food passed freely through the gastro-jejunostomy opening, but still the patient vomited freely during her stay in the hospital, and therefore an exploration was decided upon.

A great many adhesions were found to the anterior abdominal wall from the stomach and from the region of the old ulcer. Search was made among these adhesions for an anterior gastro-jejunostomy which was said to have been performed, but no signs of this were found. On turning up the transverse colon a posterior gastro-jejunostomy was discovered, with reversion of the jejunum, and within 2½ in. of the end of the duodenum. The proximal part of the jejunum had been drawn up by the contracting stomach in such a way that all bile and pancreatic juice had to enter the stomach before it could reach the jejunum beyond the anastomosis; in fact, a complete spur had formed,

and also some adhesions between the two kinks of the loop, and contraction of the aperture in the meso-colon maintained this condition. The proximal jejunum was divided close to the stomach, and the gastric end sutured and sealed, while the other or duodenal end was implanted in the side of the distal jejunum 4 in. below the gastro-jejunostomy, thus converting the operation into the well-known one bearing the name of Roux. The abdomen was closed in the usual way.

Mr. Rowlands said that gastro-jejunostomy was a very safe operation at the present time, the mortality being very low, but there are some complications connected with it which he thought were more serious than death, as all those who had to deal with vicious vomiting well knew. This condition, which does, unfortunately, still happen, in spite of all modern improvements, was, however, getting less common. It was, he considered, always due to an intestinal obstruction high up; this may be either at the proximal or the distal side of the anastomosis. In the present case he pointed out it was only on the proximal side, as shown by Dr. Hertz's X-ray method, and also at the operation. Nervous women seem peculiarly liable to the affection. It was well-known that bile and pancreatic juice enter the stomach after gastro-jejunostomy, and it was asserted that this was one of the main reasons why the operation was beneficial in gastric ulcer; yet in some women it gives rise to vomiting, in spite of a very large anastomotic opening. Various methods, he remarked, have been employed for its treatment, often without success. The most common was a lateral anastomosis between the bowel above and below the gastro-jejunostomy, but this may still allow bile and pancreatic juice to reach the stomach, and this was especially true for no-loop operations in which the lateral anastomosis cannot be made very large nor placed far enough away from the stomach. It seemed to him that the only certain way was the method he had employed in this case—i.e., that of converting the operation into a Roux and thus making it impossible for the bile and the pancreatic juice to enter the stomach through the gastro-jejunostomy opening. With regard to Roux's operation, Mr. Rowlands said it was not generally looked upon with favour as a routine primary operation, because it was more complicated than an ordinary posterior gastro-jejunostomy, which was usually very successful; moreover, that terrible sequela peptic jejunal ulcer, has followed Roux's operation in a certain number of cases, this being due to the fact that acid gastric juice unneutralised with bile and pancreatic juice was allowed to act on the piece of jejunum between the gastro-jejunostomy and the "end to side" implantation; still it was, he thought, very useful as a secondary operation for vicious vomiting.

The patient made a good recovery, and has never vomited since the operation.

## CORRESPONDENCE.

### FROM OUR SPECIAL CORRESPONDENTS ABROAD.

#### FRANCE.

Paris, Sept. 12th, 1909.

#### ULCERS OF THE LEG.

THE following method of treating ulcers of the leg has the advantage of allowing the patient to continue his occupation: After two or three days of wet dressings and the application of tincture of iodine, to insure as much as possible asepsy of the parts, a gauze bandage steeped in the following solution is wound around the limb:—

Oxide of zinc, 6 dr.  
Gelatin, 1½ oz.  
Glycerin, 3 oz.  
Water, 3 oz.

The bottle containing the mixture should be placed in hot water, before use, to render the contents as fluid as possible in order that the bandage may imbibe it

thoroughly. The winding should begin at the foot, and carried above the ulcer for about 3 in. A kind of gaiter is thus obtained which, in cooling, becomes firm, supple and elastic.

The bandage is renewed every two or three days where the ulcer suppurates a good deal, otherwise it need not be changed more than once a week. Before each new application the ulcer should be touched with tincture of iodine or nitrate of silver.

It may be well to mention that in order that the bandage should in no way impede walking, the patient should remain standing until it had cooled and become sufficiently stiff.

Under this treatment the ulcer heals more rapidly than by rest and the usual applications.

#### HÆMATEMESIS.

Hæmatemesis due to ulcer of the stomach is frequently a grave complication and always a source of anxiety for the patient and his friends; prompt treatment is consequently expected from the medical attendant.

The first indication is naturally absolute rest in bed with the ice-bag to the epigastrium, care being taken to interpose a piece of flannel between the ice and the skin. Absorption of liquid by the mouth will be strictly forbidden; only frequent rinsing of the mouth with ordinary water may be permitted; however, the patient may suck small pieces of ice.

To furnish to the tissues the necessary amount of water, an enema of a pint of boiled water may be given twice a day. After several days of this rigorous diet, two or three ounces of iced milk will be allowed, and the quantity gradually increased to one or two quarts.

If, on account of repeated hæmorrhage, it is necessary to continue the absolute diet for a certain prolonged period, two nutritive enemata will be ordered daily:—

Eggs (entire), No. 2.

Liquid pepton, 1 oz.

Milk, 10 oz.

Or, as recommended by Prof. Robin:—

Fresh eggs, No. 2.

Liquid pepton, 2 oz.

Salt, 30 gr.

Pepsin, 10 gr.

Laudanum, 3 drops.

Beef tea, 10 oz.

At the moment hæmatemesis occurs, a hypodermic injection of ergotin should be given and renewed two or three times in the day. In default of these injections, the following mixtures may be prescribed:—

Chloride of calcium, 1 dr.

Laudanum, 20 min.

Syrup,  $\frac{1}{2}$  oz.

Peppermint water, 4 oz.

Ergotin, 1 dr.

Gallic acid, 10 gr.

Syrup of turpentine, 5 oz.

A tablespoonful alternately every hour.

If the general symptoms are grave (tendency to fainting, weakness of the heart, small and rapid pulse, etc.), an injection of 10 or 20 oz. of artificial serum should be given, and at the same time an injection of spartein or camphorated oil.

Certain authorities, as MM. Dieulafoy, Terrier, and Hartmann, advocate prompt surgical interference in all these cases, but statistics are entirely unfavourable to this method of treatment, which should be reserved for cases which resist medical treatment, and they are few in number.

#### GERMANY.

Berlin, Sept. 12th, 1909.

#### NEURALGIA OF THE TRIGEMINUS FROM DISEASE OF THE NASAL CAVITIES.

A PAPER on this subject by Dr. Hoffmann, of Dresden, appears in the *Zeitschr. f. ärztl. Fortbild.*, 13/09.

The occurrence of neuralgia of the trigeminus from disease of the nasal cavities is due to proximity of the first and second branches of the nerve to the

cavities, and the clinical features of the affection correspond to the anatomical conditions. Neuralgias of the first branch are seen in disease of the frontal sinuses, after suppuration in the sphenoidal sinuses, and of the posterior ethmoidal labyrinth; of the second branch after suppurations of the antrum, of the sphenoidal sinuses, and lastly, those of the dental plexus in disease of the antrum. Symptomatic neuralgias generally make their appearance in connection with acute suppurations or exacerbations of chronic ones. True neuralgias are caused by chronic suppurations, and they form an independent affection. The majority of acute suppurations appear in connection with influenza.

In symptomatic neuralgias the nerve is almost always tender on pressure in typical spots—at the supra- or infra-orbital foramen. There is also frequently tenderness on pressure over the walls of the cavities. If the tenderness on pressure over the bony walls of the cavities is very pronounced, it supports a diagnosis of neuralgia caused by suppuration of the cavities. Tenderness to pressure over the head may accompany that over the bony walls of the cavities.

The pains may be constant for a long period, or regular intervals may intervene between the attacks. Intermittent neuralgia of the supra-orbital nerve is frequent, with acute and chronic exacerbations of suppurations of the frontal sinuses.

Although the tenderness on pressure over the nerves and bones in symptomatic neuralgia diminishes or ceases altogether during the free intervals, in true neuralgia it remains constant even during these periods of freedom.

Symptomatic neuralgias are caused by pressure of the nerve endings from exudations in the tissues of the mucous membranes. It is possible that from the course of the supra-orbital nerve in the roof of the orbit, and from the thinness of the walls of the frontal sinuses the nerve may be affected directly by the inflammatory process. This becomes more obvious when signs of periostitis are present.

In true neuralgias we must assume that the inflammatory process has extended to the nerve itself. In the differential diagnosis between true and symptomatic neuralgias the principal attention must be directed to the condition at the pressure points.

When the cause of neuralgia is to be sought in suppuration of the nasal cavities—in trigeminal neuralgia especially after influenza this connection must never be lost sight of—it can only be determined by a rhinological examination. Certain statements on the part of the patient indicate or point to the diagnosis: to the effect that the accompanying nasal catarrh is only on one side, and that the painful one, and the tenderness on pressure over the bone or nerve. Swellings of the soft parts or abscesses are of even greater significance. In acute suppurations of the antrum after influenza, redness, swelling, and œdema of the cheek of the side affected are sometimes met with; also œdema of the lower eyelids—symptoms that point to suppuration of the nasal cavities as the cause of the neuralgia.

If a nasal secretion points to a diagnosis of suppuration of the nasal cavities, it must also be made certain that this comes from one or more of the cavities. In chronic empyæma the discharge is usually purulent, in chronic catarrh muco-purulent; in acute empyæma the discharge is at first serous, and later on becomes muco-purulent.

How do we know that a discharge from the nose comes from one of the nasal cavities? When we find that the secretion comes from one side of the nose only, it makes one suspicious of suppuration from the cavities. If the secretion is uni- or bi-lateral, the swelling of the mucous membrane is reduced by cocaine; in this way the discharge can all be removed. When the nasal passage is free, we wait a few minutes, then if in a short time there is secretion of pus in the middle passage, or in the fissure between the middle turbinate bone and the septum, it is characteristic of suppuration of the cavities opening into the middle or upper parts of the nose. A negative result proves nothing, however. There is another simple way of determining suppuration of the nasal cavities. After

the nose has been freed from secretion, the patient is directed to take a mouthful of water into his mouth, the tube of the Politzer inflator is then passed into the corresponding nasal opening, the *alae nasi* closed well over it; the patient is then made to swallow as the ball is compressed. As the air pressure within the nose falls, any secretion in the cavities will be forced out. If this does not lead to any certainty, the parts must be illuminated by the electric light.

The prognosis is favourable in symptomatic neuralgia; it disappears with the cause. True neuralgias continue after removal of the cause, and require special treatment. In symptomatic neuralgia care must be taken that the discharges escape freely. This can be effected in various ways, first by making the patient use a spray of a solution of boracic acid and cocaine six times a day. The Politzer process is also very appropriate. Any hindrances to the outflow of the discharges (polypi) must be removed. Washing out of the cavities often gives great relief. The anti-neuralgics are also useful. The skin and bowels must also be attended to. In true neuralgia neurectomy of the nerve affected has been proposed. Extraction of the nerve, as proposed by Thiersch is better, as fewer relapses are likely to be met with after it than after simple neurectomy.

### AUSTRIA.

Vienna, Sept. 12<sup>th</sup>, 1909.

#### TUBERCULIN TEST.

DR. FRANZ, in his report to the Minister of War, gives an interesting history of the Bosnian Army, in which he had served during 1901-2. During that period he set himself the task of determining by the tuberculin injection the amount of latent tuberculosis under his supervision. Having satisfied himself that the injection in the healthy left no bad effects, he resolved to test No. 1 regiment of infantry, comprising 400 soldiers. The quantity used was from 3.5 milligrammes. He found 245, or 61 per cent., gave a positive result. In order to allow a reasonable space to intervene, the following year a smaller dose was repeated, with the result that 76 per cent. instead of 61 of the former year were positive, and only 24 negative, this was 14 per cent. more infected during a year's military service.

In the autumn of 1902 321 recruits were brought in and injected in the same manner, 1 milligramme, 2 milligrammes, and 3 milligrammes were given—104 times with the latter. 222 of these, or 68.8 per cent., gave a positive reaction, while only 31.2 per cent. were negative.

It was next decided to test a Hungarian regiment located in Vienna, where every care had been taken to isolate the suspected from the healthy; all enlarged glands, anæmic, bronchitic, and bodily weak were separated to a reserve body of men. After having taken all this precaution, 294 perfectly healthy soldiers were tested, and 248 of the number gave a positive reaction! It is to be noted these men were supposed to be taken from the strength of the nation, as their ages varied from 21 to 23 years: in the prime of life. Out of this 1,002 tested, who were retained on active service for the three following years, 46 were invalided or died from tuberculosis; in the fourth year 18 more, making a total of 64 of a tubercular loss. It is calculated that the Hungarian regiment lost 3.2 per cent. in 6 years, while the Bosnian lost 7.6 per cent. in the same period. It is still a debatable point how much tuberculin should be administered for testing the presence of the disease. Koch prescribed 10 milligrammes, but 3 seems to be sufficient. No inference can be drawn from the intensity of the reaction when the tubercular phenomena will appear. The hyperpyretic temperature and the simple constitutional disturbance may have the first symptoms of tuberculosis appearing contemporaneously; nothing can be inferred from the reaction as to the member or organ in which the tubercle will manifest itself.

#### CANCER AND WORMS.

At the last International Congress for Cancer Borrel put forward the theory of worms in the intestinal canal

as carriers of cancer. He had infected mice and guinea pigs, and found long after cancerous conditions of the stomach and bowels.

Kelling has since devoted his attention to the subject, and thinks we cannot go back fifteen or twenty years for the inception of the virus by worms in the alimentary canal. As three years is about the time of recurrence of the disease, he set himself to examine the subject more closely. He examined 1,036 males to obtain the frequency of worms in individuals between the ages of 15 years and 20. He found in this number

93 with *tænia*, or 9 per cent.,  
83 with oxyuria, or 8 per cent.,  
5 with ascarides, or 0.5 per cent.;

while 1,050 females gave

67 with *tænia*, or 6.4 per cent.,  
124 with oxyuria, or 12 per cent.,  
14 with ascarides, or 1.3 per cent.

The men have a heavier incidence of *tænia*, as they eat more raw flesh, while the females have a greater number of oxyuria from their intimate connection with children.

Next, taking the carcinoma incidence, from 193 cases he found among 150 men suffering from the disease that 14, or 9 per cent., had previously had *tænia*, 13, or 8.6 per cent., oxyuria, and none had ascarides.

Of the 43 females with cancer 4, or 9 per cent., had *tænia*, 5, or 11.6 per cent., had oxyuria, and none had ascarides. It will be seen from this that as many cancer cases have no parasites as those that have.

## LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

#### THE DECLINING BIRTH-RATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—“Student of Sociology,” if he refers to my letter of September 1st, may discover that I have not attributed the prosperity of Germany *solely* to their more numerous agricultural population, as he would make it appear by placing in inverted commas one or two words of mine, quite regardless of the context and its meaning. Of course there are many factors at work which determine the relative or comparative prosperity of different countries, politic and economic. However, I venture to state, without fear of contradiction, that the agricultural interests of any given community incomparably outweigh all other factors, because it is the only practical means of providing a *numerous and healthy* population, as I have often said. And in spite of this predominating advantage a country like France, so frequently referred to, does not avail itself thereof, that is their look out, and not ours. Your correspondent, however, may feel comfortable that we are a long way off from a diminishing or declining population, that is where the deaths exceed the births. Your correspondent's preachments would be much more opportune in a country, say, like New Zealand, unpopulated, but nevertheless presenting, too, a declining birth-rate. Here we have a country by illustration but recently emerged from a savage state rapidly metamorphosed into a highly civilised community. Nevertheless we read their towns are paraded by thousands of unemployed. The reason here again, I take it, is the urban population of New Zealand has too quickly outgrown its agricultural, which must obviously create unemployment and intense competition, because urban industries can only provide a limited number with both. It is certain, therefore, that any country, of whatever territorial extent, with an urban population in excess of its agricultural must, in an inverse ratio and corresponding degree, sooner or later come to grief, because, failing an adequate culture of land, there is no environment created to supply the overgrown town populations. Nowhere is this better exemplified than in our own country. Notwithstanding which your correspondent is periodically begging and praying more with emigration as an excuse.

In conclusion, Sir, your correspondent charges me with perverting facts. Can he point to one? I am sorry, moreover, he resolves not to notice my letters in future. At the same time I take his resolve as a compliment, as I think he feels instinctively the truth of what I have written, and which I trust numerous others of your readers less prejudiced may more fully appreciate. Thanking you very much for so great indulgence.

I am, Sir, yours truly,

CLEMENT H. SERS, M.R.C.S.

Brighton, September 9th, 1909.

#### MEDICINE AS A CAREER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The words of caution in your excellent "Educational Number" addressed to those contemplating medicine as a career are discreet, wise, and weighty, and it is satisfactory to find the subject dealt with also in a sympathetic fashion in a portion of the lay Press. An excellent article on it appears in one of our local organs—the *Daily Courier*—of to-day, September 4th, and I have seen similar utterances in at least one or two London papers. I write with forty years' experience and knowledge of the professional world, and in my opinion neither you nor your medical or lay contemporaries dwell sufficiently upon the hardships of the average doctor's life, and upon the disappointment which must surely overtake the vast majority of men who enter the profession with the sanguine hopes of youth, and imbued with the amount of worldly ambition natural to nearly all. There is, of course, always "room at the top." The men of transcendent abilities, the men with a touch of scientific genius, the men of intellectual calibre which throughout, from their earliest student days, marks them as superior to their fellows, will very often be able, without strain upon their powers, and without wealth or patronage, to make a fine position; and there is no doubt that a medical man deservedly eminent owing to such qualities is in an enviable situation. But the vast majority of us are mediocrities; we are men who, however intellectually superior to the common crowd—and a man must be that to become a well-qualified doctor—are on a pretty general level of ability. It is this class of candidate who need to have a true picture of the doctor's life set before them. And, in the first place, is it not grossly misleading to state that a candidate can become "qualified"—that is, in a position to earn a living—in five years. Most lads begin specialising for medicine in their seventeenth year at school. How many of these are able to earn a penny before the age of twenty-five? How many of them are able to gain a decent livelihood before thirty? Most men endeavour to get experience to complete their education by a hospital house-surgeoncy before starting in practice. Of course, if a man have means, and is able to invest in a partnership, he may give himself a better start; and if he have a modest fortune he may escape the ordeal of poverty (along with the necessity of "keeping up appearances") through which his less lucky brethren have to pass. In the work of his life the general practitioner is called upon almost throughout to display an amount of self-sacrifice demanded in no other calling, except it be in that of an ideal priest of the Roman Church. The doctor takes no vows of celibacy and poverty, but, if he marry, he is rarely able to place his wife in a position of comfort and security; he is more rarely able to make any provision for his own old age, or to ensure for his children education and advantages equal to those he himself enjoyed. The public, as a mass, do not properly appreciate the value of medical men, not being in the least aware of the labour needed to gain the position, although, of course, there are many exceptions. The State, whether represented by local authorities or departments of the central government, as you, Sir, so commonly point out, treats the doctor most vilely, and the law leaves him inferior in protection to the dentist and the veterinary surgeon. The example of the State in all departments in underpaying its medical officers, and in refusing them power and authority such as it confers upon other profes-

sional men in its employ, does much to lower respect for the profession among great classes of the public. I have left myself no room to discuss fully the position of the practitioner whose life is spent among the poorer classes. He, more than any other, is made unable to practice as a man of science; he is constantly being forced in action down towards the level of credulity and ignorance which characterises clients whose only knowledge of disease is derived from study of quack advertisements which fill so large a space in the columns of nearly all the cheap newspapers.

I am, Sir, yours truly,

A POOR PRACTITIONER.

Liverpool, September 4th, 1909.

#### "THE WONDERS OF ELECTRICITY."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Under this title and with sub-headings, "A Marvellous Machine at St. Bart's Hospital," "A Cure for Rheumatoid Arthritis," the *Pall Mall Gazette*, of Wednesday last, published an article which it is charitable to believe must have escaped the eyes of the responsible managers and editors. The article, avowedly written by a layman, serves simply to expose his ignorance of the technicalities of electrical science and of the pathology of rheumatoid arthritis. One quotation will suffice to illustrate the quality of this communication. Having first described the application of the electrode to an affected joint, it goes on thus:—"The effect is this. The portion of living flesh and bone between the electrodes is cooked—heated to almost any temperature. Do you realise this? You can be cooked until your juices albuminise, without being burnt!"

This sort of stuff we are accustomed to in the yellow press, but it seems strangely out of place in a paper which may rightly describe itself as written "by gentlemen for gentlemen." It would perhaps not call for notice were it not that the name and titles of Dr. Lewis Jones, M.D., F.R.C.P., the director of the electrical department at the hospital, are introduced in a way which might easily lead the ingenuous reader to believe that he was a party to such an indiscreet and misleading statement. It will, we doubt not, give pain to Dr. Jones and cause him some annoyance. It seems difficult to suggest any measure likely to prove effective in preventing impressionable laymen from contributing articles of the kind to newspapers, but it is not difficult to see how their publication might be easily rendered impossible in journals of standing like the *Pall Mall Gazette*.

I am, Sir, yours truly,

Ealing, W.

M.R.C.S.

[There should be some legal remedy on the part of medical men against newspapers that commit outrages of this sort upon their professional privacy.—EDITOR, M. P. AND C.]

#### SIR HENRY BURDETT AND THE ANTI-VIVISECTION HOSPITAL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—With you, I regard the methods of the Anti-Vivisection Hospital with disgust and contempt, but—also like you—I agree that the institution has its rights. If a grant be made by the Hospital Saturday Fund to that or any other hospital, it is futile and derogatory for any member of the Council of the Sunday Fund to abuse the scientific methods of the participating medical charity, however foolish they may seem. Sir Henry Burdett has written a letter to the *Times* (September 10th), seeking to justify his term "pretentious humbug," and criticising the medical methods of the Anti-Vivisection Hospital. Be the latter right or wrong, it seems curious that a layman should take upon himself to instruct the world as to the value of scientific medical technique. Sir Henry Burdett may be speaking for the Hospital Sunday Fund in all this ill-mannered recrimination, but I—speaking as a general practitioner—altogether deny and repudiate his right to speak as an authority on

scientific medical methods, much as I disapprove of those in vogue at the Anti-Vivisection Hospital. Surely the medical profession and the medical journals can speak for themselves.

I am, Sir, yours truly,  
NE SUTOR ULTRA CREPIDAM.

London, N.

### FALSE PRETENCES IN TRADE AND MEDICINE.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—At the London sessions on September 8th a firm of tobacco manufacturers were fined £10 and £220 costs for having sold, and having in their possession for sale, cigars to which a false trade description—"Havana"—was applied. The law thus deals with a class of false pretence which hardly affects anything save some Trade interests. On the other hand the law cannot, as it stands, touch the vendors of fraudulent quack medicines, the sale of which causes misery and death. In juxtaposition with the report of this cigar case in a newspaper before me there appears the advertisement of a fraudulent nostrum which "cures" at least a dozen different diseases. It contains no drug save a small quantity of aloes in each dose. Some dozen advertisements of the same kind, all demonstrated and easily demonstrable frauds, appear in the same copy of this newspaper. How long are we to wait until the law is made to deal effectually with this class of cruel swindle, and with the newspapers that knowingly derive large incomes from participating in the profits? Many papers puff these wares in editorial paragraphs.

I am, Sir, yours truly,  
A SUBURBAN PRACTITIONER.

Sept. 11th, 1909.

## SPECIAL ARTICLES.

### VITAL STATISTICS IN IRELAND.

THE report of the Registrar-General for Ireland for last year (a) is noteworthy in two facts recorded. For the first time for very many years there is an estimated increase of population, and there is a marked decrease in the death-rate from tuberculosis.

The facts relating to the former point are that the number of births registered was 102,039, and of deaths 76,891, the natural increase of population, or excess of births over deaths, being, therefore, 25,148; and that the loss by emigration amounted to 23,295 (which number is less than the number of emigrants enumerated in 1907, namely, 39,082, and also the average number—38,036—for the ten years, 1898-1907). There would, according to these figures, appear to have been an increase of 1,853 in the population on the 31st December, 1908; with respect to immigration, there is no official record.

It will be noticed that the increase of population is not due in any great degree to alterations in the birth-rate or death-rate, though the former is slightly more and the latter slightly less than the average of recent years, but to an enormous fall in the emigration rate. The average rate per 1,000 of the population for the ten years 1898-1907, was 8.6, the lowest being 7 in 1905, and the highest 10.1 in 1900. In 1908, the rate fell to 5.3. Unfortunately, the emigration figures have little relation to economic conditions in Ireland, but are governed almost entirely by the conditions in the United States of America. In fact, much of the passage money of Irish emigrants is paid for them in America by friends already settled there. The financial depression in America in 1908 is, therefore, the cause of the increase of the population of Ireland. Of the 23,295 emigrants, 10,480 were males, and 12,815 females. Of the whole number 3,547 were natives of the province of Leinster, 6,423 natives of Munster, 8,409 of Ulster, and 4,916 of Connaught.

(a) Forty-Fifth Annual Report of the Registrar-General for Ireland. Dublin: H.M. Stationery Office. 1909. [Cd. 4769]. Price 2s. 8d.

Of the total emigrants 11.1 per cent. were under 15 years of age, 81.2 per cent. were between 15 and 35 years old, and 7.7 per cent. were 35 or upwards.

The marriages registered during the year numbered 22,734. The marriage-rate was 5.20 per 1,000 of the estimated population, showing an increase of 0.06, as compared with that for the year 1907, and an increase of 0.10, as compared with the average rate for the ten years, 1898-1907; the birth-rate was 23.3 per 1,000 of the estimated population, being 0.1 above that for the preceding year, and also 0.1 above the average rate for the ten years, 1898-1907; and the death rate (17.6 per 1,000), was 0.1 under the rate for the preceding year, and 0.2 under the average rate for the ten years, 1898-1907.

Of 22,734 men married during the year, the number of minors was 377, or 1.66 per cent.; and of the women married 1,451, or 6.38 per cent., were under age. The highest proportion of husbands (2.08 per cent.) who married under age in 1908 was in the province of Ulster, and of wives (7.89 per cent.) was also in the province of Ulster. It appears that the percentage of persons married in Ireland, who were under age, is very far below the corresponding percentages in England and Scotland.

In each of the provinces of Leinster and Ulster, the highest provincial marriage rate (5.5 per 1,000 of the population, according to the Census of 1901), was recorded. The rate for Munster was 4.9 per 1,000, and that for Connaught 3.9 per 1,000. For county, or county borough areas, the highest marriage rate (7.2 per 1,000 of the population) was in the county borough of Dublin, and the lowest (3.5) in the county of Galway. Between these extremes the most favourable rates were 7.1 for the county borough of Belfast, 5.9 for the county of Dublin, and 5.3 for each of the counties of Wicklow and Antrim, and Londonderry county and county borough, and the least so were 3.7 for the county of Clare, 3.8 for the county of Mayo, and 4.1 for each of the counties of Donegal, Cavan, and Roscommon.

The births registered during the year 1908, namely, 102,039, include 52,396 boys, and 49,643 girls, or 105.5 of the former to every 100 of the latter. Of the 102,039 children, whose births were registered in Ireland during the year 1908, 99,449, or 97.5 per cent., were legitimate, and 2,590, or 2.5 per cent. were illegitimate, the latter being 0.1 below the corresponding average percentage for the preceding ten years. These results bear favourable comparison with the returns for most other countries. The number of male children born in wedlock during the year was 51,090, and of female, 48,359, or 105.6 of the former to every 100 of the latter; of the illegitimate children, 1,306 were males, and 1,284 females, being 101.7 boys to 100 girls. Of the children born in Ulster, 3.4 per cent. were illegitimate; in Leinster, the percentage was 2.6; in Munster, 2.1; and in Connaught, 0.7.

The four highest birth-rates for the county or county borough areas were 31.6 for Dublin county borough; 29.7 for Belfast county borough; 25.2 for county Kildare; and 23.3 for county Kerry. The four lowest rates were—18.3 for county Meath; 18.4 for county Roscommon; 18.5 for county Cavan; and 18.7 for King's county.

An investigation regarding multiple births was undertaken for the first time. It was found that of the total births, namely, 102,039, there were 1,198 twin births, and 10 triplets.

The six county or county borough areas having the lowest mortality rates per 1,000 of the population were:—County Mayo, 13.4; county Galway, 13.6; county Leitrim, 13.7; county Roscommon, 14.1; county Kerry, 14.2; and county Clare, 14.4. The highest rates are as follows:—Dublin county borough, 24.0; Belfast county borough, 19.4; county Carlow, 18.3; Londonderry county and county borough 18.3; county Armagh, 18.2; and county Down, 18.0.

Of the 76,891 deaths registered during the year 3,331 took place in Infirmaries and General and Special Hospitals; 1,435 in Public Lunatic Asylums; 11,268 in Workhouses and Workhouse Hospitals; and

60,857 were of persons who died "at their own homes, etc."

In the table of causes of death tuberculosis heads the list with 11,293 deaths, as against 11,679 in the previous year. Heart diseases come next with 9,020 deaths, and old age third with a little under 9,000. Until 1907 old age used to come second in the list. The change in the figures is probably due to a more accurate certification of deaths, many deaths formerly returned as due to old age being in reality due to some special disease. Of the infective diseases, omitting tuberculosis and pneumonia, the following stand highest:—Influenza with 1,798 deaths, diarrhoeal diseases with 1,199, and whooping-cough with 945. Since 1898 there has been no recorded case of hydrophobia in Ireland. The deaths from all puerperal septic diseases numbered 189, the total number of deaths associated with pregnancy or child-bearing being 615.

The number of deaths from tuberculosis was 11,293, being 386 less than in the previous year. The decrease was chiefly in the pulmonary cases.

The deaths from violence were 1,916 in number:—1,720 from accident or negligence, 48 from homicide, 147 from suicide, and 1 from execution. The accidental deaths include the deaths of 401 persons (of whom 217 were under 5 years of age), from burns, scalds, or explosions, 313 from drowning, 232 from falls, 166 caused by vehicles or horses, 115 from suffocation (of these 85 were infants under one year of age), 78 from weather agencies, 34 from poisons or poisonous vapours, and 21 from weapons and implements. Of the 48 homicidal deaths 16 were of children under 5 years of age; of the total 32 were deaths of males, and 16 of females. Of the 147 deaths by suicide, 115 were of males, and 32 were of females.

In Ireland for the whole country the death-rate of infants (97 per 1,000 births), is below that for England and Wales in 1908, namely, 121 per 1,000 births, and Scotland in 1907 (110 per 1,000). In the urban centres, however, the comparison is by no means so favourable to Ireland. In Dublin the death-rate per 1,000 births of children under one year was 146, in Belfast 147, in London 113, and in Edinburgh 122.

The Registrar-General illustrates his report by several diagrams, some of which appear for the first time. Diagram No. 4, dealing with the relations between the conjugal state and tuberculosis does not convey any meaning so far as we can make out.

A well-deserved compliment is paid to Dr. Ninian Falkner, Medical Superintendent of Statistics, for the share he has taken in the preparation of the report.

## REVIEWS OF BOOKS.

### DIET AND DIETETICS. (a)

THIS volume is divided into twenty-eight chapters, by various writers, each of which deals with a branch of the subject. The list of authors contains nineteen well-known names. Three of the collaborators are Scotch, the remainder London physicians. Sir Lauder Brunton is responsible for a very interesting Introductory Chapter, and Sir Patrick Manson and Dr. C. W. Daniels for that on "Diet in the Diseases of Hot Climates." The Editor has confined himself to Chapter XIX., "Diet in Diseases of the Lungs"; Chapter XXVI., "The Feeding of Children and Infants in Health"; Chapter XXVII., "Diet in Diseases of Children."

Dr. Sutherland is to be congratulated on the success of his undertaking. At his suggestion, contributors have given throughout the work their own views and experiences, so that in it one finds set down the principles and practice of men who have had special experience in the subject on which they write. At the

(a) "A System of Diet and Dietetics," Edited by G. A. Sutherland, M.D., F.R.C.P., Senior Physician to the Hampstead and North-West London Hospitals. London: Henry Frowde, Hodder and Stoughton. 1908.

same time the views of the leading authorities are included and critically considered. The work treats of the subject of dietary very fully, especially from a physician's point of view. There is little direct reference, however, to the more surgical side of the question—for instance, the diet of patients before or after operation. Nor is the diet during gestation particularly mentioned. In this connection a more extensive index would be a great advantage, both for those who have not leisure to read the book through, or, like ourselves, having read it, wish to refer to particular points. We have seldom dealt with a book that can be perused with greater pleasure and interest, and which is at the same time so replete with practical advice. The first nine chapters may be conveniently separated from the rest of the book, as they more or less treat of the fundamental principles of dietary. In a sense they are the most interesting and instructive part of the work, and one can obtain there a thorough insight of the significance of dietetic treatment. They deal with "The Evolution of Man's Diet," "The Physiology of Digestion," etc., "Experimental Work," "Diet Cures," "Patent and Proprietary Foods," "Alcohol," and "Artificial Alimentation." Some of the chapters necessarily contain a number of tables and some charts, which are useful for reference. The remaining chapters discuss the diet in various diseases and conditions of life. The chapter on "Diet in Tuberculosis" is particularly full and detailed, and may be taken as an example of the particular kind of information which is typical of this part of the work. In it we find the details of articles of diet for various classes of patients, arranged according to their wage-earning capacity, the approximate nutritive value of foodstuffs, their cost, and advice as to what to buy and how to cook it.

We can confidently recommend this "System of Diet and Dietetics" to members of the profession generally as a most useful addition to their libraries. The publishers, moreover, have left nothing to be desired in the printing and get-up of the book.

### THE PRACTICAL MEDICINE SERIES. (a)

THIS is the best and most practical series of year books with which we are acquainted, and the present volume will add to its reputation; but 10 volumes per annum appears to be a big investment; being American, however, further comment on the point is needless. The subjects discussed cover the whole ground of surgery, and the mode of discussion is one which renders the book of special value to the consultant and to the operating surgeon. Amongst the subjects to which special attention has been paid may be mentioned immunity, local and general; "local infiltration, hæmo- and lympho-stases, and tissue coffer-damming in acute infections"; the surgery of the heart and blood-vessels; the early removal of thrombi and emboli before gangrene takes place; and infection and contagion in cancer.

The Editor has distinct views on the administration of anaesthetics, as one may judge from the following paragraph:—"One can scarcely comprehend the degree of inefficiency with which anaesthetics are administered in many clinics and in most private practice in Great Britain, on the Continent, and in some parts of this country, unless he has been an eye-witness. With few exceptions in the European clinics, ether is given as incompletely and with as much danger as it was twenty years ago, and chloroform is continually claiming its annual wanton sacrifices, which are absolutely avoidable."

There is a good description of Trendelenburg's operation for the removal of clots from the pulmonary artery in cases of embolus. The Editor considers that it is "epoch making," but as yet it has not been performed with satisfactory results in the human

(a) "The Practical Medical Series." Comprising ten volumes of the year's progress in Medicine and Surgery. Under the general Editorial charge of Gustavus P. Head, M.D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School. Vol. II., General Surgery. Edited by John B. Murphy, M.D., LL.D., Professor of Surgery in the North-West University, etc., etc. Series 1909. Pp. 617. Chicago: The Year-Book Publishers. Agents for Great Britain: Gillies and Co., Glasgow.

subject. In the third case operated on by Trendelenburg, clots were removed and the artery successfully closed, but the patient died about 40 hours later, and at the autopsy more clots were found in both arteries. The suture of the artery was tight, and there was no blood in the pericardium. The removal of clots from arteries seems to offer more hope of success in cases of beginning gangrene of limbs. In pulmonary embolus the condition of the patient is usually so critical that even though the operation may be mechanically perfect, it seems hopeless to look for recovery.

#### OPERATIVE SURGERY. (a)

THE present or third edition of Bickham's "Operative Surgery" has been enlarged by over 200 pages and nearly 300 illustrations. The additional pages include 106 operations which were not in the last edition. The author intends his work to supply practitioners and students with an account of the technic used by modern surgeons in the numerous operations described in the text. The author rightly lays stress on the importance of a sound anatomical knowledge of the parts in operative work. He has therefore devoted a great deal of attention to descriptive and surgical anatomy. The clinical aspect of the question is only considered in a general way. The work is suitably arranged for easy reference. Part I., "The Operations of General Surgery," describes amputations and operations on arteries, bones, joints, etc. Part II., "The Operations of Special Surgery," deals with special organs and regions, as the male and female genital organs, the head, thorax, etc. In both parts the headings under which the subject is discussed are the same.

American surgical text-books, in our experience, are sometimes little more than indifferent atlases, with a scanty text, printed in large type, containing the minimum of useful information. The principal object in view seems to be to crowd in an illustration on the smallest pretext, and to make the book as bulky as possible. We have therefore the more pleasure in welcoming a new edition of this really sound work. In it the reader has not only an excellent operative surgery, but a practical and reliable surgical anatomy. The illustrations are good and efficient; the printing and general arrangement leave nothing to be desired. The author must have expended an enormous amount of labour and care in writing the subject-matter, but he is well repaid by the result. The text is full, detailed, and lucid, and describes very numerous useful and up-to-date operations. The preponderance of the more recent ones have been devised by American surgeons. Very few classical operations now in use are not dealt with. We notice in the account of entero-enterostomy by simple suture, the technic in which the posterior serous suture is first inserted is not mentioned. (It is true that technic is subsequently described under gastro-enterostomy.) The author's method is by simple continuous overhand stitching of all coats, followed by interrupted Lembert sutures of outer coats. On the whole, however, the author has utilised the space at his disposal to the best advantage. The greatest objection to the book is one of pounds and ounces. It is heavy and cumbersome.

#### PHYSICAL EDUCATION. (a)

PERHAPS one of the most remarkable characteristics of the last century was the systematic or even organised neglect of physical education. It is true that in the larger public schools of both Great Britain and Ireland much time was devoted to games, and the playing of those games resulted in much benefit to the physical health of the players. Though this was so, school authorities can claim little credit for the result. One of two courses was usually adopted by such authorities—either they enforced universal participation in such games by the pupils, and so did irreparable damage to the health of many who were

physically unfit for them, or they left the participation in and regulation of such games entirely to the discretion of the boys themselves. In girls' schools physical education was, as a rule, considered "unlady-like." To teachers and parents alike physical culture had no place in the connotation of the term education. Within the last twenty years matters have changed very considerably, but we are still very far from having as true a conception of what education means as Plato had. To anyone who will read the admirable introductory chapter to the book before us by Professor J. Welpton on the history of physical education, the truth of the statement here made will be very apparent. Until those who are responsible for the education of our youth return to some such just conception of their responsibilities as Plato had, there can be little hope of progress. Our author seems to have grasped this conception, and his book will, we believe and hope, help materially in a widespread realisation of it. The popular exposition which our author gives of the anatomy and physiology of the human body is really admirable, and may be read with pleasure and profit by anyone. If only those who are responsible for the condition of our national and primary schools throughout the country, would study the admirable instruction in school hygiene which our author gives, we should very soon hear much less of the physical degeneration of the race. The idea of attempting education in the true sense under the conditions present in many of our schools would be ludicrous were it not that it is so serious. We must thank Dr. Welpton for his book, and sincerely wish that we could ensure that the study of it should become universal throughout the country.

### LABORATORY NOTES.

#### MILK STOUT.

THE physician has constantly to emphasise the necessity for taking additional nutriment, and when a revulsion to an increase in bulk of solid food is apparent the plan of enhancing the nutrient value of existing articles of diet is constantly resorted to. Where no compunction need be felt against the prescription of malt liquors, we would direct attention to this "milk stout," which is made by Messrs. Mackeson and Co., Limited, of Hythe, Kent. In so far as our analysis shows the absence of fat, the term "milk" must be considered in a restricted sense, and it would probably be a difficult matter to prepare a palatable stout in which the ingredients of whole milk were incorporated. This stout, however, contains the carbohydrates of milk, which very considerably increase the nutrient value, without the additional quantity of extractives being apparent to the taste. The stout has an excellent flavour, and is likely to be much appreciated by patients.

Our analysis shows it to have the following composition:—

Extractives	...	...	9.60 per cent.
Mineral matter	...	...	0.35 "
Alcohol (by volume)	...	...	6.17 "
" (as proof spirit)	...	...	10.81 "
Fixed acid (as lactic acid)	...	...	0.07 "
Volatile acid (as acetic acid)	...	...	0.11 "

### MEDICAL NEWS IN BRIEF.

#### Medicine Stamp Duty.

In the House of Commons, on Thursday last, Captain Craig asked the Secretary to the Treasury what was the amount of revenue derived from the duties on quack medicines in the years 1905-6, 1906-7, and 1907-8 respectively.

Mr. Hobhouse replied that the amounts of revenue derived from the medicine stamp duty, to which I take the hon. member to refer, in the years 1905-6, 1906-7, and 1907-8 were £324,112, £327,106, and £334,142 respectively.

(a) "A Text-Book of Operative Surgery." By M. S. Bickham, M.D., F.R.C.S., Junior Surgeon, Touro Hospital, New Orleans; late Surgeon, Manhattan Hospital, New York, &c. &c. Third Edition. Pp. 1208. 854 illustrations. Philadelphia: W. B. Saunders Co. 1908.  
(b) "Principles and Methods of Physical Education and Hygiene." By W. P. Welpton, B.Sc. Octavo, pp. xix. and 401. London: W. B. Clive, University Tutorial Press, Ltd. 1908.

Captain Craig: Is this extraordinary increase in quack medicines to be attributed to a certain extent to the fact that the label put on the bottles by the Government to collect the duty is taken by certain people among the poorer classes to mean that the contents have the Government approval?

Mr. Hobhouse: I do not think so. There is no extraordinary increase, only from £324,112 to £334,142.

Captain Craig: That is an increase of £10,000 on duty alone on the sale of these medicines.

#### Important Prosecution of a Nurse at Exeter.

A CASE of considerable importance came recently before the magistrates at the Exeter Police Court, when Alice J. Bowden was summoned for exposing, before disinfection, clothing which had been used in connection with an infectious disorder.

Mr. C. T. Proctor (Deputy Town Clerk) stated that Mrs. Bowden was a widow, who had been nursing a child, at Alphington Street, suffering from scarlet fever, and went to her home every evening without changing her clothes. She had a son residing at home, who was engaged at a large draper's establishment; a daughter, who washed clothes for a large institution, and another one who went home every night for about two hours.

The Magistrates' Clerk: What is the remedy?

Mr. Proctor: Change her clothes, or disinfect herself, before leaving the house of the patient.

Continuing, Mr. Proctor said a person who exposed such clothing without disinfection was liable to a penalty not exceeding £5.

Defendant said she did not think she would do any harm by leaving the house; had she known, she would not have done so, and would have stayed there, as she had done since Monday.

The Chairman of the Bench (Mr. Stocker) said nurses were expected to have sufficient knowledge of what was required to protect other people from infection. She would be fined 10s. He hoped the case would be a warning to other people.

#### International Medical Congress, Budapest.

IN connection with the International Medical Congress held at Budapest, an exhibition of drugs, chemicals, medical and pharmaceutical appliances, arranged at the Zander Institute by Burroughs Wellcome and Co., attracted considerable attention. The exhibit included a selection of "Tabloid" and "Soloid" products of special interest to medical practitioners, and other scientific workers "Tabloid" first-aid equipments, "Tabloid" photographic chemicals and specimens of all the newer preparations of the firm were on view.

#### The Cholera in Russia.

THE City Councillors of St. Petersburg, after a stormy night sitting, have resolved upon the immediate construction of additional filters on the plans and terms offered by the firm of Siemens and Halske. The only other competitor was a Russian firm. Cholera continues to claim an average of 25 victims daily. The total for the year is 5,769 deaths, of which 88 per cent. are among the working classes. Preventive inoculation was applied to 53,162 inhabitants, of whom only 12 contracted the disease, and 8 of these recovered. A telegram from Pskoff reports that riots have taken place among the peasantry in connection with the outbreak of cholera there. The peasants destroyed the cholera wards of the hospitals and assaulted doctors. The constabulary have been sent to quell the disturbance. The Pskoff peasants are notoriously the most backward in all Russia.—*Times*.

#### Hospital Dilemma in Salford.

A SINGULAR situation has arisen in Salford as a result of the termination of his engagement by Dr. Buchanan, senior resident medical officer of the workhouse hospital after 4½ years' service. The guardians advertised for a successor to Dr. Buchanan, but there was not a single applicant for the position. This is believed to be due to the attitude assumed by the British Medical Association, in view of the fact that the guardians are proposing to reduce the status of

the senior officer, and are advertising the post at £150 per annum, or £70 less than Dr. Buchanan received, whereas Dr. McVail, in the report of the Royal Commission, stated that with 500 patients in the institution he was of opinion that the medical staff was insufficient, and that the work seemed bound to be rushed, while only a few weeks ago Mr. Lowry, the Local Government Board inspector, pointed out the necessity for increasing the medical staff, which hitherto consisted of two resident medical officers and a visiting medical officer.—*Standard*.

#### Two Attendants Dismissed from Hope Hospital, Manchester.

THE ill-treatment of a sane epileptic patient in the Hope Hospital of the Salford Poor-law Union was considered at a recent meeting of the Visiting Committee. The patient, through a relative, complained that an attendant named Clark had struck him, dragged him from a ward, and had "nearly strangled him." The attendant Clark said the patient had refused to do certain work, and had thrown himself on the floor. Clark's statement was corroborated by Mr. Perkins, head attendant.

Henderson, another attendant, said that he set the man to work, and that Clark interfered, telling the man to "take no notice of that officer," and as the man refused to go, Henderson alleged that Clark struck the patient and dragged him into the corridor.

Henderson said that he only gave evidence because there was bad blood between him and Clark.

Mr. Byrne asked if that had influenced his evidence?

The Attendant: Yes, it has done so.

Mr. Byrne: In what way has it influenced you?

Henderson: If it had not been for that I should have kept my mouth shut.

Mr. J. P. Byrne moved, after the attendants left the room, that both should be dismissed, and Mr. Shutt seconded the resolution, which was carried.

#### The Feeding and Care of Infants.

WE have been favoured with a large printed card containing some practical directions as to the feeding and care of infants. It is issued by the National League for Physical Education and Improvement, which has its headquarters at 11 Southampton Row, London, W.C. The card is one of the most trustworthy and sound that we remember to have seen. The cards are excellent for the nursery or for the out-patient room, and would be found useful by health visitors. They are to be bought at 11d. per dozen.

#### Statue to the Memory of Sir James McGrigor, M.D.

IN September, 1865, a statue by Noble was erected in the Ranelagh Gardens, Chelsea Hospital, in memory of Sir James McGrigor, the first Director-General of the Army Medical Department. For some time it was felt that the new Royal Army Medical College, Grosvenor Road, would be a more fitting place for this memorial of an officer whose career was so greatly associated with the Army and the advancement of medical science. Accordingly, permission was obtained from the authorities concerned, and the statue has been re-erected on a site in the grounds of the college on the north-east side facing the Tate Gallery. The cost has been defrayed by the officers of the Royal Army Medical Corps.

#### Medical Congress at Budapest.

THE International Medical Congress came to an end on the 5th inst. A telegram was sent to King Edward, notifying his Majesty of the acceptance of the invitation to hold the next congress in London, and conveying the most respectful thanks of the congress. A similar despatch was sent at the same time to Sir Edward Grey.

THE will, just proved, of the late Mr. Richard Vincent Coleman, of The Shrubbery, Buckland, Dover, who left gross estate £41,383, with net personalty £33,269, provides that his residence shall be used as a convalescent home, either in connection with the Royal Victoria Hospital, Dover, or otherwise, as his trustees shall think fit. The ultimate residue of his property—about £25,000—is left as an endowment for the home.

## NOTICES TO CORRESPONDENTS, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

### SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs 15.12. Messrs. Dawson and Sons are our special agents for Canada.

### ADVERTISEMENTS.

For ONE INSERTION:—Whole Page, £5; Half Page, £3 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 18 insertions, at £3 10s.; 36 at £3 3s.; 53 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

### PLAGUE IN THE PUNJAB

**SURGEON-MAJOR MCN.**—The following question and answer in the House of Commons comes in the nick of time for your information. Mr. Rees asked the Under-Secretary for India whether the returns of plague mortality in the Punjab during the preceding years indicated that the disease was gradually disappearing; and how last year's death-rate on this account compared with that from small-pox.—The Master of Elibank (Peebles and Selkirk, Min.): The plague mortality in the Punjab in 1908, excluding native States, is given in the most recent returns as 30,708, against 608,685 in 1907. The death-rate from plague in that province in 1908 was 1.53 per thousand; that for small-pox was 1.42 per thousand.

**MR. J. WILBERFORCE.**—The company, as its name suggests is of American origin. Fortunately, its existence here has been brief, as its pretentious humbug appeared not to catch on with the public as have so many other quack nostrums, and we understand its affairs are about to be wound up in bankruptcy. Thanks for your congratulations. We think this journal had something to do with the result.

### BEECHAM'S PILLS.

INTERLOCUTORY injunctions to restrain certain chemists from selling pills as "Beecham's" which were not of his manufacture, came before Mr. Justice Dodd in the King's Bench, a few days ago. We are, of course, precluded from comment on the case while *sub judice*, but the following is the description of these pills in the British Medical Association's report on "Secret Remedies":—"A box of these pills, advertised to be worth a guinea, is sold for 1s. 1½d., and the prime cost of the ingredients of the 56 pills it contains is about half a farthing. In a circular wrapped round the box it is stated that 'these renowned pills are composed entirely of Medicinal Herbs,' and cure constipation, headache, dizziness or swimming in the head, wind, pain, and spasms at the stomach, pains in the back, restlessness, insomnia, indigestion, want of appetite, fullness after meals, vomiting, sickness of the stomach, bilious or liver complaints, sick headaches, cold chills, flushings of heat, lowness of spirits, and all nervous affections, scurvy and scorbutic affections, pimples and blotches on the skin, bad legs, ulcers, wounds, maladies of indiscretion, kidney and urinary disorders, and menstrual derangements. The pills had an average weight of 1½ grains, and analysis showed them to consist of aloes, ginger and soap; no other medicinal ingredient was found. The quantities were approximately as follows:

Aloes	0.5 grains.
Powdered ginger	0.55 "
Powdered soap	0.18 "

In one pill."

This analysis is confirmed by that previously published by the Australian Royal Commission.

**A VEGETARIAN.**—Spinach has been found on analysis to contain a larger quantity of iron than any other vegetable; cabbage and endive coming next respectively.

**H. S. M.**—All the English medical schools commence the winter course the first week in October. You will find your other questions answered on reference to our "Educational Number."

### THE THERMOS FLASK.

WE are asked to state that Lieut. Shackleton has testified to the fact that this marvellous flask helped him to perform his wonderful feat in reaching the South Pole, and that a telegram from America has just been received, giving the information that Dr. Cook found these flasks "life-savers" at the North Pole.

**F. E. F. (Ealing).**—There is little fear of cholera obtaining any real footing in England. However, isolated cases may occur anywhere, and it is the duty of every practitioner to be on the alert. Meanwhile, it is reassuring to know that special precautions are being taken by Dr. Williams, the medical officer of the Port of London, for the prevention of the introduction of cholera into the metropolis. The real anxiety is as to the spread of the disease in the ports of Holland, and particularly

at Rotterdam, which is daily in close contact with London, not only by the passenger steamers but by a large number of cargo boats.

## Vacancies.

**Gorey Union.**—Medical Officer for the Camolin Dispensary District. Salary £120 per annum, with Registration and Vaccination Fees, etc. Immediate application to B. Creighton, Clerk of Union. (See advt.)

**Fermanagh County Hospital, Enniskillen.**—House Surgeon (Anæsthetics). Salary £72 per annum. Applications to C. Wilson, Secretary. (See advt.)

**Devon County Asylum.**—Third Assistant Medical Officer. Salary £140 per annum, with board, apartments, and laundry. Applications to Medical Superintendent, Exminster.

**British Ophthalmic Hospital at Jerusalem.**—Assistant Surgeon. Salary £300 per annum, with house. Applications to the Honorary Secretary, British Ophthalmic Hospital, St. John's Gate, Clerkenwell, London, E.C.

**Newcastle-on-Tyne Dispensary.**—Visiting Medical Assistant. Salary £160 per annum. Applications to the Hon. Secretary, Joseph Carr, Chartered Accountant, 26 Mosley Street, Newcastle-on-Tyne.

**Manchester Royal Infirmary.**—Resident Surgical Officer. Salary £150 per annum, with board and residence. Applications to Walter G. Carr, General Superintendent and Secretary, Manchester Royal Infirmary.

**Prestwich Union.**—Assistant Medical Officer. Salary £140 per annum, together with furnished apartments, rations, etc. Applications to Edward W. Ogden, Clerk to the Guardians, Union Offices, Cheetham Hill Road, Manchester.

## Appointments.

**BRICK, MICHAEL, L.R.C.P. and S.Irel.**, Certifying Surgeon under the Factory and Workshop Act for the Tralee District of the county of Kerry.

**BRICE, THOMAS H., M.D. Edin., F.F.P.S. Glasg.**, Regius Professor of Anatomy in the University of Glasgow.

**CORFIELD, WALTER FRANCIS, M.B., B.S. Lond.**, Medical Officer of Health of Colchester.

**EMERSON, J. J., L.R.C.P. and S.Irel.**, Certifying Surgeon under the Factory and Workshop Act for the Enno District of Queen's County.

**FORREST, MARGARET G., M.B. Glasg.**, Assistant Medical Officer at the Bucknall Fever Hospital, Stoke-on-Trent, Staffordshire.

**GREGG, C. C., M.B., C.M. Aberd.**, Certifying Surgeon under the Factory and Workshop Act for the Fyvie District of the county of Aberdeen.

**HIGGINS, T. F., L.R.C.P. F.R.C.S. Irel.**, Certifying Surgeon under the Factory and Workshop Act for the Stradbally District of Queen's County.

**LEA, JAMES, M.B., B.C. Cantab.**, Certifying Surgeon under the Factory and Workshop Act for the Chorley District of the county of Lancashire.

**MC FARLAN, WILLIAM MOREHEAD, M.D., Ch.B. Edin.**, District Medical Officer by the Basingstoke (Hants) Board of Guardians.

**SUTHERLAND, HALLIDAY G., M.D. Edin.**, Medical Superintendent of the Westmoreland Sanatorium, Grange-over-Sands.

**WALLACE, D., M.B., C.M. Edin., M.R.C.S. Eng., F.R.C.S. Edin.**, Certifying Surgeon under the Factory and Workshop Act for the Creetown District of the county of Kirkcudbright.

## Births.

**AIDISON.**—On Sept. 7th., at Northwood, the wife of Christopher Addison, M.D., F.R.C.S., of a son.

**BECKETT-OVERY.**—On September 8th, at 99 Cromwell Road (Nursing Home), South Kensington, the wife of H. Beckett-Overy, M.D. Ed., F.R.C.S. Eng., of a daughter.

**CREAN.**—On September 9th, at 13 Queen Street, Mayfair, the wife of Thomas J. Crean, V.C., F.R.C.S., of a son (still-born).

**SELEY.**—On Sept. 10th, at 13 Hall Gate, Doncaster, the wife of E. Wallace Selby, M.D. Lond., F.R.C.S., of a son.

**SHORE.**—On Sept. 11th, at Byron's Lodge, Grantchester, Cambridge, the wife of Lewis E. Shore, M.A., M.D. Cantab., Fellow of St. John's College, Cambridge, of a son.

## Marriages.

**EPWORTH-JACKSON.**—On Sept. 8th, at the Parish Church, Hoxham, Norfolk, Frank Arthur Epworth, M.B., F.R.C.S., of Rotherham, son of B. G. Hepworth, Esq., of Dewsbury, to Hilda Constance, daughter of the late Edward Steane Jackson, M.A., of Plymouth.

**MALINS-BALDWIN.**—On Sept. 7th, at St. Nicholas' Church, Warwick, Herbert Malins, B.A., M.B., F.R.C.S., second son of Edward Malins, M.D., of Birmingham, to Florence May, eldest daughter of Harry S. Baldwin, Ashberry House, Warwick.

## Deaths.

**BRIDGWATER.**—On Sept. 8th, at Uckfield, Thomas Bridgwater, J.P., LL.D., M.B., for 35 years one of the medical officers to Harrow School, aged 85.

**PENHALL.**—On Sept. 10th, at "The Cedars," Broadwas-on-Teme, Worcester, Sophia, the beloved wife of John Thomas Penhall, M.D., formerly of St. Leonards-on-Sea.

## NOTES AND COMMENTS.

### Another Christian Science Victim.

OF all forms of unqualified practice that of so-called Christian Science is perhaps the most revolting, inasmuch as it seeks its victims under the guise of the highest principles of morality the world has yet known. It is to be hoped that this foolish cult will ere long be banished from our midst with the rest of the impostures that are born of greed and bred upon ignorance. Meanwhile Christian Science has to be dealt with as a deadly menace to society. Elsewhere in our columns we publish an account of a recent inquest, held at Worthing, upon the body of an unfortunate widow who died of hæmorrhage from a phthisical lung while under the care of a Christian Scientist. The evidence showed that the poor woman had been under the care of a London physician, but, acting under the advice of a sister, she had placed herself in the hands of a local Christian Scientist, with whom arrangements for a course of treatment were made. The sum of five shillings a week was paid for the precious ministration, which consisted of prayers twice daily. As well might it be expected to turn the stars in their courses by supplication of the kind as to influence thereby the course of a disease like consumption controlled by natural physical and pathological laws. On the other hand, it is well known that many cases of pulmonary tuberculosis may nowadays be treated by proper medical treatment.

### The Price of the "Work."

ONE of the most extraordinary features of this case, and one that lets a flood of light upon the mercenary motives of the followers of Christian Science, was the remark of the operator in this case, to the effect that "a good deal of work was not charged for." That points to the deliberate prostitution of a sacred function to the base level of a means of gaining a livelihood. If the Christian Scientist be logical he will establish a standard price for his "work"—so many prayers, so many pence, shillings or pounds, according to the credulity and the depth of pocket of his dupes. But what has the State to say of the lives that are sacrificed to this blatant form of unqualified medical practice? What have the General Medical Council to say to the Privy Council as to the desirability of substituting prayer for physic? Lastly, what have the Royal College of Physicians to say to the sacrificing of lives by these "false practitioners," whom, by the terms of their original Charter, they are bound to proceed against? The terms of that Charter of Henry VIII. have been repeatedly confirmed by Parliament up to the Medical Act of 1858. If the General Medical Council cannot prosecute, why do they not press the Royal Col-

lege, which has had the fullest powers (in London and 7 miles round) for several hundred years?

### Blindness Among Infants.

IT is stated that the authorities of five of the chief Staffordshire pottery towns, having made application to the Local Government Board, have been permitted to include *ophthalmia neonatorum*—purulent conjunctivitis—among diseases compulsorily notifiable under the Act. The fact that this disease is not notifiable generally throughout the country is deplorable. Like so many others of the sanitary measures enacted during past years, the Notification Act is largely disregarded by authorities. The Act declares that they "may," not that they "shall," adopt its provisions; and from apathy, slackness, or parsimony, they too often, to a greater or less extent, neglect it. It is estimated that of the cases blind from childhood one-third are owing to conjunctivitis of the new-born. Notification of this disease, when the Act is adopted, is not only obligatory upon the medical attendant, but upon the head of the family, and perhaps, what is most important, upon the midwife. With prompt and efficient treatment, the eyesight, even in a majority of cases including the most virulent, can, as every practitioner is aware, be saved. Perhaps, when the results of a year's action in the Potteries are made known, the example may be followed in other localities where, among a vast, poor, and too often ignorant populace, application of all the laws devised for the preservation of the health of infants and children is most urgently called for.

### Medical Progress.

"THE less one knows about the past, the more one is sure that the present represents great progress over what has been accomplished." . . . "The more one goes back to the story of the past, the more does one realise that human history is a series of discoveries followed by forgettings and then re-discoveries." The truth of these two statements is well illustrated by instances taken from the history of medicine. Professor Walsh, of New York, in a paper read before the Johns Hopkins Historical Club (*Johns Hopkins Hospital Bulletin*, July, 1909), quotes sufficient instances to show that there were great schools even before Johns Hopkins. A law of the Emperor Frederick II., of the year 1241, commanded, as the curriculum of study for a young physician, three years spent in the study of logic, followed by four of medical study. At the end of that time the graduate was to spend a year in practice, "with advice and under the direction of an experienced physician," before venturing to practice independ-

ently. This is a much higher standard of medical education than was in vogue six centuries later. In surgical work, De Chauliac, in the fourteenth century, forestalled modern abdominal surgery. He opened the abdomen in order to stitch wounds of the intestine, described a method of suture, and invented a needle-holder. A print of the thirteenth century represents a surgeon operating for hernia with the patient in the Trendelenburg position. This highly developed surgery was rendered possible by the use of anaesthetics, the preparation in most common use being a combination of opium and mandragora. Facts such as these are a useful corrective to our high opinion of our own importance in the world, and Dr. Walsh does a good service in bringing them to our notice.

#### Some Plans of the Entomological Committee.

It is announced, regarding the research committee of economic entomology, that arrangements are being made with the view of sending a skilled entomologist both to West and to East Tropical Africa. These officials are desired not only to make collections, but to instruct residents in the use of scientific methods. In that way it is hoped that a large mass of accumulated facts will be one day available as the basis for extended observation and study. We are glad to gather that the scope of the work will not necessarily be restricted to Africa. This departure of the Government marks a new era in medical science which we hail with feelings of the liveliest satisfaction. The principle involved is the recognition of the duty of the State to further all knowledge that tends to make the world healthier and safer from disease. It is to be hoped that what the British Government is doing in Africa to-day it may be doing to-morrow at home, and thus the adequate endowment of medical science will become an accomplished fact. There are a host of familiar, but wholly obscure, conditions of disease in the British Islands that await investigation. Rheumatism and whooping-cough, to take two examples, although they lack romance, are hardly less deadly in their way than malaria and sleeping sickness. If we are ever to have a Government that will deal logically with urgent social wants, the endowment of medical research will probably be one of its first steps.

## LEADING ARTICLES.

### A SELECT COMMITTEE ON PATENT MEDICINES.

AFTER years of incessant protest against the evils of the trade in secret remedies the views so long advocated by THE MEDICAL PRESS AND CIRCULAR appear to be nearing a successful issue. The General Medical Council have so far taken up the subject as to press upon Government the desirability of a Royal Commission upon irregular medical practice. That they should not have specifically included patent medicines is to be regretted, because the evils due to the use of secret remedies pure and simple, that is, without the mediation of an unqualified person posing as a medical adviser is probably infinitely greater than the train of human miseries and disaster which follows in the track of the false medical practitioner. Logically, however, the question of irregular medical practice must include the consideration of secret remedies, inasmuch as the greater includes

the less. There could hardly be a clearer instance of unqualified practice than that of a man who professes to cure certain diseases by the sale of a certain nostrum. He is taking money on the strength of a promise which, from the scientific point of view, it is impossible he can fulfil. If a transaction of that kind be not irregular medical practice then we may reasonably demand from the State, in whose hands the control of social contracts is vested, a rigid definition of what is legitimate and what is illegitimate. These and other subsidiary matters, however, will have to be threshed out sooner or later in the full light of official inquiry. On Thursday last, September 16th, the Home Secretary practically promised the appointment of a Select Committee next session to inquire into the sale of patent medicines. This important announcement was made in response to a question addressed to him by Captain Craig, who has on previous occasions shown a practical interest in the question. He asked the Home Secretary whether he would consider the advisability of issuing regulations making it compulsory on all manufacturers of medicines liable to patent medicine duty to print on the label on the bottle, or other vessel in which such is sold, the full ingredients of such bottles or vessels, as well as the diseases they purport to cure; whether he would consider the advisability of increasing the size of the lettering of the Government stamp as a further precaution against ignorant people believing that the contents are guaranteed by Government? In answering, Mr. Herbert Gladstone said he was in communication with the Privy Council with reference to the point in the first part of the question, and he was disposed to think the matter of sufficient importance to require an inquiry by a Select Committee next session. New designs for stamps and labels had recently been adopted, and were being prepared, which would clearly indicate that the stamp *did not* imply a Government guarantee. Although in making this statement Mr. Gladstone was careful not to commit himself to any definite action, yet the terms of his answer are most encouraging, for they show that the question of quackery has at length been forced into the field of practical politics. It is to be regretted that it was left to a lay member of the House of Commons to call attention to the matter, in spite of the fact that there are a fair number of strong and well informed medical men in Parliament. At the same time one may recall the services of medical members of Parliament in the past and the certainty that when the call for action comes they will not be failing in their duty. For our own part we regret exceedingly that the question of the sale of patent medicines has not been deemed worthy of the appointment of a Royal Commission. We further regret that the tenour of Mr. Herbert Gladstone's answer points to the retention of the patent medicine tax, which we regard as a mean and disastrous dealing with an unclean thing on the part of the State. If the evils of secret medicine trading are as vast and far reaching as we think them to be, then they should be swept off the face of the earth, instead of giving

them the protection of the State in return for a paltry stamp revenue. Lastly, we commend to the medical profession the careful consideration of the fact that the Home Secretary refers matters concerning quacks and quackery to the Privy Council, and that the General Medical Council is closely connected with, and presumably guides and directs, the policy of the Privy Council. This is an important official acknowledgment of the relation of the General Medical Council to the Government—and it is to be hoped that the medical profession will in future keep steadily in view the fact that all matters of medico-social bearing are referred by the Government to the Privy Council, which is practically the mouthpiece of the General Medical Council. Henceforth, the plea of the latter body that they have not powers to deal with this or that matter therefore falls to the ground. The Home Secretary, in open Parliament, has made the statement that he has referred to the General Medical Council a matter involving the protection of the public against patent medicines, that is to say, he has consulted the Council on a matter they have hitherto regarded as outside their field of activity.

#### HEALTH IN INDIA.

THE usual Report on the public health in India, for the year 1907-8, which was issued last week in the form of a Parliamentary paper, affords, as these reports nowadays almost invariably do, most satisfactory reading. Improvement in the health of the European population has made truly enormous progress during the last three or four decades. This has been, in the first place, due largely to the wiser habits of life, which have been gradually adopted by all classes, military and civil. It is impossible to estimate the amount of "Indian liver," which has been put an end to merely by a more rational dietary, including far smaller quantities of beer, and brandy and soda, than used formerly to be considered indispensable. In spite of the fact that excessive dram-drinking still prevails to some extent among the rank and file of the British troops, the death-rate for the year from diseases of the liver was only 1.01 per 1,000, against 1.52 of the previous report. Pure water supply has almost extinguished cholera, and has vastly reduced the amount of enteric fever; the death-rate from the latter, the principal among all causes of mortality, during the year being 2.77 per 1,000, against 3.19 in 1906. The improvement in the sites of cantonments has also produced good effects; and given a good constitution, and careful habits—or at least not reckless habits—there seems no reason why a standard of health should not be maintained in India quite as high as that possible at home. Life in India is moreover essentially an open-air life by night as well as by day, whilst the sunlight and warmth are decided enemies of diseases so prevalent at home, such as gout, rheumatism, and their allies. The number of officers from the military and civil services, or of men from civil life, who retire from India as chronic invalids, has within late years been reduced to very small proportions, and it is not too much to say that the vast majority now return at the

end of their career displaying no injurious mark upon their constitution due to their prolonged residence in a climate once thought necessarily harmful. The death-rate, both of the British and native troops, during the year was the lowest on record, although the mortality from pneumonia, the chief cause of death, among native regiments was as usual high. It contributed 31.8 per cent. of the total deaths, five times more than among the European troops, the whole death-rate being 1.99 per 1,000, against 1.56 in 1906. The difficulties, great as they may be, in safeguarding the health of native troops, are trivial compared with the question as it affects the general native population. Among these the death-rate was higher than in 1906, a total of over half a million more deaths being recorded. The increase was largely due to plague—the disease most difficult to combat among the natives. In the towns it is impossible to make sufficient impression upon insanitary surroundings, to prevent overcrowding, to reduce dirt, and to purify a surface soil saturated with the filth of a thousand years, although much is being done in all possible directions. There are besides the obstacles presented by superstition, and prejudice; but even these are to a large extent being overcome by the devoted services of the medical profession, and the army of lay helpers—paid and unpaid—by whom they are supported. In the history of British rule in India, it can hardly be possible to find a brighter page than that which narrates the vast benefits that have been conferred upon the populace by medical science, and by the self-sacrificing labours of those who have striven throughout to give practical shape to the lessons which that science has so forcibly inculcated.

---

#### CURRENT TOPICS.

##### The late Dr. Cawas Lalcaca.

A TIMELY memorial of a brave deed has been issued by the Edinburgh Parsi Union in the shape of a small pamphlet giving a notice of the late Dr. Cawas Lalcaca, of Shanghai. The tragedy of his death at the Imperial Institute, on July 1st, 1909, is fresh in the minds of our countrymen. It was in the attempt to save Sir Curzon Wyllie, a popular retired Anglo-Indian official and Political A.D.C. to Lord Morley, from the murderous attack of a fanatic that he himself was fatally shot. This noble self-sacrifice formed a fitting crown for a well-spent life. Cawas Lalcaca was a member of a well-known Parsi family at Baroda, in the presidency of Bombay. In 1878 he matriculated at the Grant Medical College, Bombay, where he graduated M.B. in 1883 with first-class honours. Later he proceeded to England, where in 1885 he took the joint diploma of M.R.C.S. England and L.R.C.P. London, and in the same year he graduated M.D. of Brussels. In the following year he settled down in Shanghai, where he held several professional appointments and acquired a large practice. At the time of his death, which occurred during a visit to England, he was a leader of the Parsi community in China. The record of his career, both social and professional, is one of life-long devotion to the high

ideals of duty and to the noble traditions of the profession in which he proved so worthy an ornament. There could hardly be found a more fitting inscription for his monument than the words of Lady Curzon Wyllie:—"The brave and noble man who lost his life on the night of July 1st in trying to save my beloved husband and others."

#### **Discovery of a Mummified Body at Stamford.**

At Stamford a leaden coffin was recently discovered in the course of some drainage excavations on the site of the former Black Friars Monastery in that ancient town. The partially mummified body of a woman was found inside the coffin, with a sheep-skin document in Latin, bearing the name of Johan. It is suggested that the body is that of Joan, the "Fair Maid of Kent," widow of Thomas, Earl of Kent, who afterwards married the Black Prince, thus becoming Princess of Wales and mother of King Richard II. It is announced that the local authorities of Stamford, in their wisdom, refused burial in the local cemetery to the remains, which have been buried in a field outside the town in a wooden coffin. The fact that the mother of an English king, or, for that matter, of any other person similarly unearthed from its resting-place, is denied burial in the common cemetery or burial ground lights up with a sudden revealing flash the sordid narrowness of the modern provincial mind, especially where burial, sacerdotal or otherwise, is concerned. As a rule, there is a local medical antiquary in all old towns, whose voice is ever raised against the vandalism and the smug futilities of small-brained iconoclasts. If there were such a practitioner of medicine in the neighbourhood, doubtless he did his best to stay the desecration of the "mummified remains found in the garden at Stamford." In any event, supposing the identity of the body to be established as that of the princess, it is incredible that the State and the reigning Royal Family will permit it to lie in its present undignified position.

#### **Shakespeare's Doctors.**

It is always of interest to medical men to notice the view taken of their profession by the great men of literature. The treatment of doctors in the works of Rabelais, Molière, George Eliot, Thackeray, Trollope, to mention only a few, has often been studied, and it is hardly any wonder that the attitude of Shakespeare to our profession has more than once received attention. The subject is brought to our notice afresh by an article in the *Glasgow Medical Journal* for July, from the hand of Dr. William Findlay, better known in literary circles as "George Umber." It appears that seven doctors appear on Shakespeare's stage—Dr. Caius, in "The Merry Wives of Windsor"; Dr. Butts, in "Henry VIII."; an English doctor and a Scottish one in "Macbeth"; one in "King Lear"; Cornelius, in "Cymbeline"; and Ceremon, in "Pericles." It is satisfactory to find that Shakespeare treats these personages with dignity and consideration, in marked contrast to the ribald satire of Rabelais, and the scorn of Montaigne. Ceremon, the lord of Ephesus, and noble physician, is perhaps the most dignified of these characters, while Dr.

Caius, the French physician of Windsor, a choleric, fire-eating old gentleman, is the least so, but is nevertheless, far from being a contemptible person. The Scottish doctor in "Macbeth" is an eminently safe and shrewd practitioner, who is careful not to speak beyond his book, and though sufficiently fond of "profit," would willingly rid himself of a troublesome patient. It is an interesting suggestion, by the way, that Ceremon had his prototype in Shakespeare's own distinguished son-in-law, Dr. John Hall.

#### **Public-House Phthisis.**

THE agency of public-houses in the spread of consumption is a fairly self-evident fact. It figured somewhat prominently in a recent Report of the Medical Officer of the Woking Urban District Council, and was quoted in the local newspapers. The suggestion was warmly resented by certain members of the Council, and a discussion ensued, the result of which appears not to have materially damaged the position of the temperance party. A letter was read from Mr. John Burns remarking on the enormously disproportionate mortality among publicans and publicans' servants compared with the rest of the community. The President of the Local Government Board also pointed out that medical observation showed that alcoholic indulgence greatly lessened the resistance to attacks of disease, and that it would be difficult to find a place in which there is more indiscriminate spitting than on the floors of public-houses—and it is agreed that spitting is the chief means by which human consumption is spread. From the report of the Woking discussion we gather that the weight of objection was against the publicity, rather than against the public-house. In any case, the incident shows that the Medical Officer of Health who contemplates a tilt against the evils of alcohol will do well to see that his armour is complete and his weapons in good order before entering the lists.

#### **The London County Council and School Clinics.**

THE action of the metropolis with regard to its defective school children is of importance because of the example set to the rest of the kingdom. It is of general interest, therefore, to note the growing conviction in many quarters that the decision of the Council to avail themselves of a few of the existing voluntary charities is hardly likely to be permanent. The mass of professional opinion is dead against the arrangement, which is regarded as another wholesale deprivation of the just dues of the general practitioner. It remains to be seen whether the hospitals who have entered into the agreement with the Council will face the emphatic disapproval of the British Medical Association. The members of the honorary staff, as well as the Boards of every voluntary hospital in London have been circularised by the Association, so that there can be no plea of ignorance of the facts of the case. It would be nothing less than a catastrophe were the members of the medical staffs of certain hospitals to throw down the gage of defiance to general practitioners. The upshot would be a class warfare that would end almost inevitably in the boycotting of the consultants. As it is, the latter hold the key to the

position, for the medical work of the hospitals depends entirely on the honorary staffs. They have only to act loyally in union with the outside medical men in order to secure and consolidate the common professional interest which has suffered so much in the past from the incessant inroads of vicarious philanthropy

#### Alcoholic "Tonics."

A FEW days ago at the Westminster Police Court a firm of druggists were summoned by the Excise for having sold various alcoholic "tonics" without a licence. The prosecuting officer explained to the magistrate that there were certain wines, such as quinine, ipecacuanha, and antimony wine, which were so medicated that they could not be used as beverages, and when wines of that description were mentioned in the British Pharmacopœia, and were sold by properly registered chemists and druggists, the Inland Revenue did not interfere, provided the wines had been sold purely as medicines. The wines in question were not of that class. The presiding magistrate, Mr. Francis, said that he would never agree to impose anything more than a nominal penalty on a chemist for a *bona fide* sale of these things, and awarded only a fine of 5s. and 2s. costs on each of four summonses. Mr. Francis is one of the most experienced of London stipendiaries, and if his view is shared by his colleagues on the Bench, a great encouragement will be given to the trade in alcoholic "tonics." It has been recently shown that the great majority of these mixtures now on the market contain as much alcohol as ordinary port wine. Some of them may be compounded of fine wine with ingredients deserving to be styled tonics, but there is nothing to prevent dishonest dealers from concocting mixtures of which the alcoholic constituent is merely raw "silent" spirit. It is impossible even for a trained "palate" to discover what is the exact quality of mixtures made up with beef tea, or syrup, and flavouring materials, whilst the majority of people who consume them take them innocently as medicines, not expecting them to be very palatable; and a great many secret habitual drunkards, especially among women, use these concoctions merely to satisfy their craving. It is much easier to send to the chemist for another bottle of "tonic" than to the wineshop for a bottle of brandy; and the "tonic" need not be concealed, but can be exposed to excite the feelings of sympathetic friends. No alcoholic mixture, of any kind, ought to be prescribed without the sanction, and supervision, of a qualified medical man; and if the traffic in these preparations is to be allowed to develop unchecked, a great part of the new legislation for prevention of the evils of the drink traffic will be certainly neutralised.

#### Health of British and German Navies.

PUBLICATION of the report of the Health Department of the German Navy for the year 1907 renders possible a comparison between it and the British report for the same year. The total German naval force numbers 45,776 men, and the British 108,740. Cases of disease and injury numbered respectively 25,051 and 75,351. This gives an approximate ratio in the German record of 547, and in the

British of 693 per 1,000. The larger ratio in the British Navy is accounted for by the greater proportion of ships employed in the Tropics. It is, however, remarkable that the German ratio for ships in the Mediterranean amounts to 984 per 1,000, against 680 British. The ratios of venereal diseases show a large British excess, 124 per 1,000, against 59 German. It is stated that elaborate prophylactic measures against venereal diseases are taken in the German Navy, whilst the men in the British fleet are virtually left to take their chance—a most deplorable, and it might justly be added, disgraceful fact, which urgently calls for attention and investigation. Suicides in the German Navy amounted to 23, and in the British to 19; ratios respectively of 0.50 and 0.17 per 1,000. There seems no reason why the medical departments of the two navies should not, in this essential humane endeavour, be brought into friendly relations, so that they might together study each others problems and methods, with a view to mitigation of all influences affecting the health of their fleets. In the question of venereal disease alone it seems urgently desirable that the British authorities should make themselves fully acquainted with German methods and means of prevention.

#### PERSONAL.

A PAPER will be read at the Royal Society of Medicine by Dr. Frederick W. Hewett, M.V.O., on "The Need for Legislation in Regard to Anæsthetics and the Lines upon which it Should take Place."

THE centenary of the birth of Oliver Wendell Holmes will be celebrated by the New York Medical Society in October next. Our distinguished *confirre* was born on August 29th, 1809, in the same year as Darwin.

THE opening address of the London School of Tropical Medicine will be delivered on October 26th by Professor Osler, Regius Professor of Medicine in the University of Oxford. The American Ambassador will preside.

WE understand that Dr. R. J. Collins, Medical Superintendent of the First Aid, Home Nursing, Health, and Infant Care Classes, connected with the Education Committee of the London County Council, has resigned his position.

MRS. HENRY FAWCETT, LL.D., will give the introductory address, "On Pioneering," at the opening of the Winter Session of the London (Royal Free Hospital) School of Medicine for Women on October 1st, at 4 p.m. Mrs. Garrett-Anderson, M.D., President of the school, will preside.

DR. E. A. WILSON, of Cheltenham, who was Second Medical Officer, zoologist, and artist in the *Discovery*, has accepted the post of Medical Officer for the Captain Scott expedition to the South Pole. Dr. Wilson did some zoological work among the penguins on the occasion of his former expedition, and published a volume through the Natural History Museum.

DR. H. A. MIERS, F.R.S., Principal of the University of London, has consented to deliver the prizes to the successful students of St. Mary's Hospital Medical School, Paddington, at the opening of the Winter Session on Friday, October 1st, when the annual dinner of past and present students will be held at the Café Royal, Regent Street, at 7 o'clock the same evening.

# A CLINICAL LECTURE ON DECALCIFIED DIETARY IN ARTERIAL ATHEROMA.

By MAURICE LOEPER M.D., and XAVIER GOURAUD, M.D.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

THE majority of writers on the treatment of chronic arteritis deal almost exclusively with the manifestations and morbid disturbances, which make up the clinical picture, leaving on one side the vascular lesions, which constitute its anatomical basis. Many of the published observations tend, moreover, to maintain a very regrettable confusion, for they lack the absolute criterion which can be afforded only by exact microscopical and anatomical data, and when we endeavour to deduce any therapeutical conclusions therefrom, we are apt to comprise in the same investigation all non-specific chronic arterial lesions, irrespective of their course, their extent, and their histological constitution.

The vascular walls may be the seat of necrosis and fatty degeneration, hyperplasia, inflammation lesions, and foci of calcification. Every one of these anatomical states represents a distinct morbid process, if not, indeed, a distinct disease, which, however commonly associated, must not on that account be confounded.

This distinction is necessary, not only from the experimental point of view, it is even more so from the point of view of pathological human anatomy, and Professor Teissier, in an interesting contribution, very properly observes that sclerosis and atheroma do not give rise to the same symptoms, and we may add that they do not appear to be dependent on the same pathogenesis, or to be amenable to the same measures of treatment.

We only propose, on this occasion, to discuss arterial calcification, whether present in a pure form, as is sometimes met with experimentally in certain animals, or associated with one or other of the preceding lesions, as is usually the case in man. It has been by no means proved that calcification of the arterial walls is, as suggested, a process of natural defence on the part of a weakened wall, while, on the other hand, it is obvious that the calcareous patch constitutes, *per se*, an irremediable lesion, and a danger which it is the physician's duty to limit, and, if possible, prevent.

In view of the impossibility in man, of obtaining the experimental accuracy that is afforded by anatomical examination, we are constrained, notwithstanding the objections that may be raised to this method, to work out certain pathological problems by experiments on animals.

We are acquainted with a large number of toxic products, alimentary and otherwise, which act on the vascular system and leave indelible traces of their influence (tobacco, ergotine, cayenne pepper, oxalic acid, putrefactive products, poisonous mushrooms, etc.), but we are not in a position to affirm whether or not there exist, side by side with the highly toxic products derived from our daily food, other substances, believed to be inoffensive, which may interfere with the nutrition of the blood vessels and favour the occurrence of calcification.

In a recent communication of ours, published in conjunction with Dr. Boveri, we suggested the hypothesis that one of the substances which plays such an important part in building up our tissues and maintaining their tonus, one, too, which repre-

sents the chemical substratum of atheromatous lesions, *lime*, might conceivably play a predominant part in the production of these lesions.

The researches which we have carried on for upwards of a year past appear to support this hypothesis, showing, as they do, that a rise of the calcic co-efficient may, like an increase of chloride of sodium in oedema and hydræmia, be the cause, not, indeed, of the arterial lesion, but of the precipitation of lime that follows in its wake.

Arterial tissues unquestionably display a peculiar affinity for lime. It is present therein in considerable quantities (1.20 in rabbits, 1.40 in cows, and 0.40 in man), and in this respect the only tissues that contain a larger proportion are bones and cartilage. Then, too, the accumulation of lime salts in the vessels is very obvious in animals that normally consume food rich in lime, in those fed on food to which an excess of calcareous substances has been added, and, lastly, in those in whom the proportion of calcic substances increases with age. It seems to us that the ready calcification of the arteries of the rabbit and cow, and of the vessels of the aged, whether animals or man, may well be consequent upon this accumulation.

Our recent observations showed us, moreover, that among the substances that commonly provoke atheroma (adrenalin, ergotine, and oxalic acid), a certain number lead to an increase of lime in the cardio-vascular tissues long before the slightest lesion of calcification is perceptible, even under the microscope.

With adrenalin, even after the second injection, we found 1.31 per 1,000 in lieu of 1.15 in the control animal, while with ergotine the difference is still appreciable, exceeding 10 centigrammes.

The lime retention seems further to be confirmed by the reduction in the lime eliminated in the urine and fæces, and no better evidence of this is needed than the diminution in the basic phosphates in man, following the injection of a milligramme of adrenalin, and of the total lime (0.035 instead of 0.070) after a tolerably large dose of ergotine (2 grammes).

In short, in the arterial tissues already strongly impregnated with lime under ordinary conditions, the injurious action of certain irritating substances is manifested, to begin with, by a more or less pronounced rise in the calcic co-efficient, which will be more or less rapidly followed by precipitation in a new chemical form of salts thenceforth insoluble.

The seemingly rather ingenious hypothesis which we have put forward to explain the rôle of lime in the production of atheromatous lesions is to some extent borne out by actual observation. Further proof of its accuracy appears to be afforded by two series of experiments on animals: if a large quantity of lime salts be given daily to an animal the action of small doses of arterial poisons determine very extensive lesions of calcification, and if, on the other hand, rabbits are placed on a diet poor in lime (carrots and bran) we may still get arterial lesions but with much more difficulty than in the control animals fed on cabbages, rinds and greenstuff.

We infer from what precedes that it is indispensable to limit the intake of lime to the *strict nécessaire* in drawing up the dietary for persons threatened with atheroma, and for the actually atheromatous.

At all periods of life man requires lime, but as he gets on in years the proportion actually necessary progressively diminishes. An adult should not take more than 1.10 a day, the intestinal and urinary elimination amounting to about 90 centigrammes. Elimination ought to be proportional to intake, and it is obvious that in the atheromatous, and in renal and cardiac subjects, and even in elderly persons who are merely suffering from a general slowing down of the functions, elimination is less active, and retention is more likely to occur.

With regard to the richness of various food stuffs in lime, the tables drawn up by Atwater, Balland, and Armand Gautier enable us to classify them in three groups:—

(1) Substances very rich in lime, exceeding 2 per 1,000, viz., cows' milk, cheese, eggs, onions, beans, green cabbage, and strawberries.

(2) Substances moderately rich in lime, between 1 and 2 per 1,000: mares' milk, peas, lentils, haricot beans, and cauliflower.

(3) Substances poor in lime, below 1 per 1,000, viz., bread, meat, brain, most kinds of fish, potatoes, asparagus, apples, pears, plums, cherries, etc.

With regard to drinks, wine rarely contains more than 0.30 per 1,000, but it may attain 0.20 in spring water, and as much as 0.50 in certain mineral waters, St. Galmier, Pougues, etc.

It is hardly necessary to add that the richness in lime salts of this or that food is not, *per se*, a sufficient reason to forbid it, for we must take into account not only the actual percentage but the proportion in which the food or beverage is usually consumed. The following table gives sufficiently practical data on this point:—

4 to 800 grammes of bread=	45 to 70 centigrammes of lime.
150 to 200 grammes of meat=	19 centigrammes of lime.
3 eggs=	10 to 15 centigrammes of lime.
200 grammes of milk=	40 centigrammes of lime.
160 grammes of dry vegetables=	5 centigrammes of lime.
200 grammes of green vegetables or spinach=	20 centigrammes of lime.
500 grammes of potato=	8 to 10 centigrammes of lime.
15 grammes of cheese=	8 to 10 centigrammes of lime.
90 grammes of fruit=	2 centigrammes of lime.
150 grammes of beef tea or soup=	20 to 40 centigrammes of lime.

A glance at this table shows that large amounts of milk, bread, beef-tea and green vegetables should be forbidden for atheromatous subjects. Rumpf, Carell and Senator had hesitatingly pointed to the desirability of restricting the use of some of these substances.

In drawing up a dietary we must no doubt take into account the degree of absorption, the variable assimilation of the lime contained in the food, and the ease with which it is eliminated or accumulates. The various factors are part and parcel of the nature of the calcic compounds. The bicarbonate and lactate of lime are assimilated and eliminated more readily than the sulphates and phosphates. Their presence in certain food substances increases both their absorption and their assimilation. Then too their administration in the form of diluted solutions allows them more readily to pass through the in-

testinal mucosa and through the kidney. This important question demands further investigation.

If it be desirable to impose an acalesc dietary on the atheromatous it is equally desirable to promote the elimination of lime *via* the urine, the intestine, and even by the skin. According to our estimates the normal man passes daily in the urine some 16 or 20 centigrammes of lime. Under an acalesc diet this proportion falls to 0.12 while on a milk diet it rises to 0.40 or 0.61. It also falls in almost all acute maladies except tuberculosis, nephritis and cardiopathies (as low as 0.03). Although under normal conditions the kidney does not allow lime to pass to any great extent, certain drugs are capable of stimulating its elimination; digitalis, theobromine and coffee raise the output to from 30 to 35 centigrammes, as do also very small doses of ergotine; small doses of iodine and the iodides (to 61 and even 81 centigrammes); lastly, the ingestion of considerable quantities of water and diuretic infusion notably accelerates the medicinal elimination.

The intestine is the principal emunctory for the excretion of lime. Under normal conditions the fæces contain from 46 to 60 centigrammes of lime daily. Purgatives increase this elimination. Taking into account the quantity of water taken therewith we found that an ounce of sulphate of soda increased the amount to 90 centigrammes; drastic purgatives, such as aloes, gave from 80 centigrammes to a gramme, so that in patients with an over charge of lime the use of aperients is plainly indicated.

There is not much to be said with respect to cutaneous elimination, although the scales of the epidermis always contain a very high proportion of lime. It may be noted, however, that the administration of iodine increases the proportion of lime in the skin from 0.87 to 3.28 per 1,000.

A very simple therapeutical measure which would be really curative were it not delicate and even dangerous, would be to administer substances capable of getting rid of the lime that has accumulated in the tissues or rendering soluble the lime precipitated in the atheromatous patches.

We have investigated the action of acid lemonades, iodides, and bicarbonate of soda. In spite of Ferrier's opinion, we have no hesitation in forbidding acids, even in small doses, especially for prolonged use. Their solvent action on calcified patches is more than doubtful, and, what is more, they dissolve the lime out of the bones and cartilages, thus giving rise to the presence in the soft tissues of large quantities of soluble lime salts.

In the course of our investigations we have found twice as much lime as normal in the muscles of animals taking acids. Treatment by acids is assuredly risky for it culminates in a result diametrically opposed to the one we are aiming at.

It is indeed remarkable that lactic and citric acids, which increase the proportion of lime in the soft tissues (1.40 per 1,000 in lieu of 0.52) favour the production of atheroma in animals and may even directly determine its supervention.

The anti-atheromatous action of iodine and the iodides has been the subject of a great deal of discussion. It is affirmed by some and as stoutly denied by others. We have sought to ascertain whether this drug exerted any decalcifying action which would be one of the causes of its efficacy.

We took two lots of eight guinea pigs. Of each series four were given daily 5, 10 and 20 centigrammes of iodide of potassium the four others remaining as controls. After three weeks they were killed and their organs calcined and treated in the usual way, with the following results—

(A) 0.10 and 0.20 cg. of Iodide		Controls	
Bones ...	122 per cent.	163	per cent.
Muscles ...	2.9 "	0.52	" "
(B) Iodide ... 0.05 cg.			
Bones ...	154.42 per cent.	154.25	" "
Muscles ...	1.36 "	0.57	0.52 "
Skin ...	3.28 "	0.87	" "

The iodides, therefore, almost invariably increase the proportion of lime in the soft parts and consequently in the vessels. In strong doses, indeed, they are capable of attacking the fixed lime of the bones, displacing it, it may be, into a less convenient situation.

Iodine is unquestionably a decalcifying agent, but, like the acids, its decalcifying action is in no wise elective, and it often culminates in an actual surcharge of the soft parts in lime.

We do not think that bicarbonate of soda is open to the same objections. In doses of 10 to 15 centigrammes daily, in animals, it appears to provoke a notable diminution of the amount of lime contained in the cardio-vascular tissues (0.90 in lieu of 1.10 in the rabbit) while the lime contents of the bones underwent no change.

In the regimen and treatment of prospective atheroma and the actually atheromatous it is therefore of importance to distinguish between preventive and really curative agents. Preventive medication comprises the establishment of a regimen as poor as may be in lime salts and the administration of remedies that promote the elimination, especially *via* the urine and intestine, of the *mobile* lime salts of the economy. Curative measures are vastly less effectual and may be dangerous and should never consist in the administration of acids and large doses of the iodides because these substances set the lime of bone and cartilage free, and transport it into the soft tissues, the lime co-efficient of which is thereby augmented. It is better to employ bicarbonate of soda, which, according to our experiments, is capable of removing the lime from the soft parts without touching the fixed lime in the osseous and cartilaginous structures.

**NOTE.**—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by J. Rutherford Morrison, M.B., F.R.C.S., Lecturer on Surgery in the University of Durham; Senior Surgeon to the Royal Victoria Infirmary, Newcastle-on-Tyne. Subject: "Two Cases of Intestinal Obstruction."*

## ORIGINAL PAPERS.

### THE ADOPTION OF NOTIFICATION OF PHTHISIS BY LOCAL AUTHORITIES. (a)

By G. CLARK TROTTER, M.D., D.P.H.,

Medical Officer of Health, Paisley.

THE subject which I have the honour of introducing has, during the past year, been under review by many local authorities, and therefore, from point of view of interest alone, should well lend itself for discussion. After briefly referring to the circumstances which have led up to the present advanced view, I propose to give a short account of our experiences so far in Paisley.

Two systems of notification of pulmonary phthisis are commonly in use—(a) voluntary notification, which is optional on the part of the medical attendant; and (b) compulsory notification

under the Infectious Disease (Notification) Act, 1889.

In addition I may add (c) notification of all forms of tuberculosis. This last system is at present being much discussed, and may be the eventual goal, just as we are now progressing from voluntary to compulsory notification of phthisis, so in time we may advance to that of all tubercular affections.

Voluntary notification, although it has many supporters, especially in England, is inadequate. There being an option, the medical man has in most cases to consider the wishes of his patient. This narrows down the notifications to mainly hospital and dispensary patients. Another factor, one which has a considerable influence on the number of voluntary notifications, is the sanatorium or other means of treatment available. If this is freely provided, naturally more notifications are received. Voluntary notification, although of some value—for, after all, the cases so notified are so many possible sources of infection brought to the notice of the Health Department—has been in many towns unsatisfactory. Many cases are notified shortly before death, while the number of phthisis deaths registered very largely exceeds the notifications.

I pass now to compulsory notification. The way for the adoption of phthisis pulmonalis under the Infectious Disease (Notification) Act, 1889, has been opened by the Amendment of the Public Health (Scotland) Act, and by circulars of the Local Government Board. In May, 1905, the Board issued a schedule of inquiry on the "Administrative Control of Pulmonary Phthisis," to ascertain what efforts were being made to check the spread of the disease. In March of the following year (1906) the Board declared pulmonary phthisis an infectious disease within the meaning of the Public Health (Scotland) Act, 1897, and stated that for the effective application of the Act a system of notification was essential, but notification had no administrative value unless followed by curative and preventive measures. On August 28th, 1907, the Public Health (Scotland) Amendment Act came into force.

This modifies sections 57, 58, and 59 (dealing with prevention of infection) of the Public Health (Scotland) Act, 1897. The words "proper precautions against spreading disease or infection," being used instead of "free from disease and infection," and subject to this proviso school attendance, occupations connected with food, and use of public conveyances and ships (with which these sections deal) are made possible.

By these alterations phthisis was brought under the sections of the Act without being harsh to the individual, and the Board, in July, 1908, issued a third circular reiterating its recommendations regarding the administrative control of the disease. This, then, is the brief history of what has led up to the adoption of notification as one of the measures of control.

A considerable number of local authorities have now adopted one or other system of notification; the object of this paper is to invite from the various representatives an account of their experiences in their districts.

As regards the attitude of the public towards notification, the harmonious working of the methods of control depends largely upon the tact of the officials. The information desired may be obtained and the instructions imparted in practically every case without arousing feelings of resentment. Among the poor it is by means of notification that their needs become known, and the visitor is not unwelcome.

(a) Paper opening discussion at the Annual Congress of the Incorporated Sanitary Association of Scotland, at Ayr, September 1st to 4th, 1909.

As regards the profession, in a voluntary system the etiquette of professional secrecy is a real difficulty, and largely limits the notifications to the poorer classes.

Compulsory notification, a statutory obligation, frees, as it were, the medical man.

The medical attendant may, in certain cases, consider visitation at the time not advisable in the interests of the patient. We have had no difficulty in Paisley in obtaining particulars from the medical man himself, and disinfection has been welcomed.

*The System in Paisley.*—Last year, under my predecessor, Dr. Robb, it was agreed by the local authority to add permanently phthisis pulmonalis to the compulsory notifiable diseases under the Notification Act; to appoint a qualified nurse to visit; to provide sputum flasks; to disinfect frequently houses, bedding, etc.

The compulsory notification came into force on March 1st of the present year.

I was able to obtain the services of a phthisis visiting nurse from the Victoria Dispensary, Edinburgh, who commenced her duties on April 5th.

On receipt of the notification she visits the home, not in an officious manner, but, if I may so express it, rather in an "Elberfeld" way, gains the confidence of the patient and relatives, and instructs them as regards ventilation, cleansing of rooms, etc. The information she has gleaned she tabulates on a card. The inquiry does not essentially differ from what is asked in other towns; it has been condensed, as an experienced visitor does not require the prompting headings suited to non-phthisis trained.

The item "Clark Fund" refers to a local charity for consumptives.

#### INQUIRY CARD.

##### FRONT.

Name	Address	Register No.
Visited	M. F.	
Occupation	Sex	Age
	Married	Dr.
Has there been a change of occupation		
Able to work	Full time	Part time
In bed	How long ill	Occupants of same bedroom or bed
relationship, history of cough or consumption among these or visitors	Other inmates of house and	
	Phthisis Pulmonalis.	

##### BACK.

Exmn. of sputum	
Habits as to spitting	General condition, well to do, badly off, food, etc.
" " washing clothes	Been in Sanatorium
" " alcohol	Assisted by societies, Clark Fund, etc.
Sources of infection	
General appearance of house (clean, damp, dirty smelly)	
No. of windows	Can they open
by day	By night
Previous addresses within two years	Are they

The card system I find a decided advantage in many ways. The cards of those on the visiting list can be kept separate. The cases ending fatally can be picked out and form a separate bundle.

When classifying according to location, age, sex, occupation, or any of the items of inquiry, one has but to rearrange the cards. Should a card be mislaid it is of small consequence, as there is an efficient check both by actual notifications received and also by the entries in the register of notifications. The phthisis notifications are entered in a register of compulsory notifications designed by Dr. Robb, the heading of which is equally applicable to phthisis—

#### REGISTER HEADINGS.

No.	Date of Notification.	Name of Patient.
Age.	Residence.	No. of Ward.
Date of Visit.	Date of Onset or Illness.	Occupation.
Phthisis Pulmonalis.	Removed to Hospital.	
	Medical Attendant.	

##### HOUSEHOLDER.

Name.	Occupation.
Inmates.	
Adults.	Children.
Apartment in House.	Clean or Dirty.
Ashpit and Privy.	Water Closet,
etc.	Milk Supply.

##### SCHOOL.

Name.	Class.
Date of Disinfection.	Result.
Recovered.	Died.

##### Remarks.

Multiple notifications are not re-entered, but a note is made under first entry.

Cases abstracted from the registrar's death returns are entered in red ink.

Before passing on to the results noticed so far since the adoption of notification, the following figures, taken from the Registrar-General's report for 1908, giving the death-rates from phthisis in several towns, may be of interest. The rate is expressed as per 100,000 living—Perth, 183; Dundee, 169; Glasgow, 138; Leith, 127; Paisley, 124; Edinburgh, 122; Greenock, 122; Aberdeen, 95. Paisley holds, then, as regards phthisis, a medium position.

The results from visitation of the homes by the nurse have been very good. The houses have improved in cleanliness to a marked extent. A number of cases have removed to better houses. Those found in lodging-houses have moved to institutions or better accommodation. The windows are opened. The sputum flasks lent, and the disinfectants provided, by the department are used.

There were notified for the five months from March to July 103 males and 95 females; total, 198; which, making corrections for non-burghal cases, gives 91 males, 92 females; total, 183.

As regards age, these burghal cases were as follows:—

##### MALES.

-15	15-20	20-25	25-35	35-45	45-55	55-65	65 up
7	9	14	20	22	13	6	—
FEMALES.							
17	11	10	29	15	7	2	1

In England phthisis is more prevalent among adult males, owing to the nature of their work. It

will be noticed that, after adding the 7 male children under fifteen years of age, the women and children make a total of 99. It will be an interesting question when the notification has been in force some little time to estimate how far the flat system of living may be a cause of this. I believe it is a factor as regards rickets.

The percentages as regards house accommodation were found on visitation to be—In lodging-houses, 1.95 per cent.; one-apartment houses, 18.18 per cent.; two-apartment, 62.33 per cent.; three-apartment, 11.68 per cent.; four apartments and upwards, 6.2 per cent. The two-apartment is, of course, the commoner class of house in Paisley. About half the cases visited are in receipt of charities or poor relief.

The trend of present-day hygienic methods is towards home visitation and instruction. The great advances of recent years in sanitary matters have accomplished much, but can the progress due to building construction and outside sanitation keep up the pace?

I have been, as I have said, struck by the results of house visitation both in the department of phthisis control and infant visitation. Sometimes I think it is interesting to look backwards not only as regards progress in preventive measures, but also as regards opinions held years ago. Over forty years ago Lord Derby, speaking at Liverpool, said:—"No sanitary improvement worth the name will be effected, whatever Acts you pass, or whatever powers you confer upon public officers, unless you can create a real and intelligent interest in the matter among the people at large. Whatever administrative measures can do for public health—and they can do a great deal—they can never supersede the necessity for personal and private care. The State may issue directions, municipal authorities may execute them to the best of their power, inspectors may travel about, medical authorities may draw up reports, but you cannot make a population cleanly or healthy against their will, or without their intelligent co-operation. The opportunity may be furnished by others, but the work must be done by themselves. That is why, of the two, sanitary instruction is even more essential than sanitary legislation."

I believe our advances as regards the health of the community beyond the stage at present attained will depend largely upon home visitation, that the opinion of Lord Derby may be taken as a prophecy for to-day. It is by these means, united, of course, with such curative measures as dispensaries, sanatoria and isolation homes, that we may hope in time to reduce the phthisis cases to numbers comparable with other infectious diseases, and the cost of their efficient treatment would then cease to be excessive.

## HOW TO DEAL WITH THE QUACK MEDICINE TRAFFIC. (a)

By J. C. McWALTER, M.A., M.D., D.P.H.,  
F.F.P. & S.G.,  
Barrister-at-Law.

OVER two million pounds—say £2,400,000—have been spent in quack medicines in Great Britain since the last meeting of the British Medical Association, and as toll from this infamous traffic the Government has received £300,000 from the Inland Revenue stamps which cloaked them.

The concurrence of the Government in this traffic has become a national scandal. No other reputable legislature on earth has consented to take from quack medicine vendors what may be described as the "wages of sin." There is, indeed, a small tax in the

United States on proprietary articles, but as their composition must be set forth on the label, the money may be considered as comparatively untainted. The Government of France tolerates no quack remedies—home or foreign; the ingredients must be made known to the police. The German Government have even a stricter rule. Were our flourishing quack medicine makers, who take over £2,000,000 per annum from the sick and ignorant, and pay £300,000 to our Government, to attempt to carry on their calling under like conditions in Italy, or even Russia, the police and the gaol await them.

Grasp the significance of two million pounds! It would provide £100 per annum for every medical practitioner in the British Isles, assuming them to number 20,000. It would be more than amply sufficient to endow such a State Medical Service that everyone who wanted medical help in these countries could obtain it absolutely free of charge.

That two millions of money are wasted on quack medicines each year is, after all, only an economic argument against their encouragement. How many hundreds of thousands die because of their use every year? This is the aspect of the problem which it becomes the British Medical Association to attack. It is not suggested that many thousands die each year actually poisoned by those drugs, but it is certain that an enormous number are brought prematurely to their graves by neglecting to obtain proper treatment for their diseases, through confidence in the promises of quack medicine makers, and by being drained of their resources to purchase these drugs, whereby they become unable to procure either such comfort as they require, or orthodox medical care. It is also certain that an enormous number of young infants are drugged to death by being treated with opiates and narcotics when suffering from bronchitis or the like.

Great Britain now remains the only great Power that tolerates the growth of unchecked quackery of every human disease, and the scandal must be removed. Already certain of the colonies—Australia, the Cape, Canada—are grappling with the evil, and America, where the quack medicine evil had attained greater power than even with ourselves, is vigorously squelching it by the Pure Food and Drug Act of 1902.

If we could induce Parliament to adopt this American Act, with a few modifications, the trouble would be ended. Every medicinal compound exposed for sale would set forth on the label the proportions of alcohol, cocaine, morphine, or other poisonous ingredients which it contained, as well as a statement of its composition. Such a solution of the problem would knock the bottom out of the traffic. Your purple pill person makes his hundreds of thousands by telling the anæmic artisan that his pills owe their virtue to some secret drug, unknown and unprocurable elsewhere. If he is bound to set forth on the label that the ingredients are sulphate of iron and carbonate of potash, the mystery vanishes, and fraud is impossible. If a man does by chance discover an improved formula or a new and useful combination of remedies, he can always be certain of a certain preference. Many of the remedies of our Pharmacopœia—Dover's Powder, James' Powder, Heberden's Ink, Griffith's Mixture, Huxham's Tincture of Bark, Fowler's Solution, and the like—were at one time more or less secret remedies. In time their formulæ became public property, and, instead of being for the benefit of their discoverers only, they are now available for the benefit of mankind. This is the medical as opposed to the commercial spirit, and it is on these lines I propose we should treat all the so-called patent medicines.

The solution, then, of the quack medicine problem is simply this—that makers of the nostrums should be required to set forth the ingredients on the label. This is practically the American remedy; but, after all, the problem in the United States has been very much like the problem with us; the results appear to be satisfactory, and we should not be too proud to follow a good example from a kindred people.

Assuming that the disclosure of the ingredients is the remedy for the quack medicine trouble, how can we insist upon it? An Act of Parliament at once

(a) Paper read at the Belfast meeting of the British Medical Association.

suggests itself, and would be the procedure if you had a Minister of Public Health; but we have no such Minister, and the difficulty of procuring such a Bill might be insuperable. All the power and influence of our Association has not been able to bring the new Medical Act into being, and if we cannot suppress open unqualified practice of medicine by law, we can scarcely hope to interfere with an insidious form of the evil which brings the Treasury in £340,000 a year.

An Act of Parliament is, therefore, probably impracticable, and we must try to deal with the evil within our present powers. What can be done? Already a notable beginning has been made by Dr. Hope, of Liverpool. That capable Medical Officer of Health reflecting that prosecutions were frequently and successfully brought under the Food and Drugs Act for the sale of drugs "not of the nature, substance, and quality demanded," brought a certain quack medicine maker into the police court on the ground that he had sold a medicine as a specific for liver complaints, whereas it was an acidified solution of glycerine, worthless for that purpose, and hence sold to the detriment of the purchaser. The magistrate convicted in this case, and thus a remedy of the quack medicine evil is at once apparent—namely, that the Medical Officer of Health of each district should collect samples of these patent medicines which promise definite cures of definite disease, have an analysis made, and if the composition be shown to be quite incompatible with the claims made for the article, and on the strength of which it was sold, order a prosecution.

The public have often hitherto asked why doctors did not get analyses made of the quack remedies which they denounced, and either expose them or prescribe similar articles. We know that the practical difficulties of competent analysis have been great, and the legal risk of action for misrepresentation even greater, and that our private practitioners dare not tackle the job.

On the other hand, the patent medicine people have traded on our inertia and proclaimed their products as something undiscoverable by analysis and unknown to the faculty. The difficulties about the analysis have now been largely overcome by the action of the British Medical Association in having analyses made, evidently by most skilled and competent hands, of practically all the so-called patent medicines on the market. The results are a revelation. We find that the most largely-lauded remedies, which have made fortunes for their owners, consist of the crudest, commonest, and cheapest drugs, which, if prescribed by the physician, would often be rejected as worthless.

The importance of this work of the Association has not been properly appreciated; it is an undertaking which possibly no other Association could have attempted, and the analyses are such as no other journal would dare to print. The policy of bluff and bounce is much believed in by patent medicine makers, and if any private individual, or any ordinary journal had published the results of the analysis of those patent medicines, they would have united as one man and pooled all their capital to crush the individual or the journal. Knowing the power which lies behind the British Medical Association, the patent medicine proprietors have not dared to attack the journal—in fact, in not a single instance has the correctness of the analysis been questioned. Their policy, however, has been to choke and smother up the results. Thus, although these analyses of patent medicines, of which the names were household words, would be of immense public interest, it does not appear that a single newspaper in the three kingdoms published the results. Even the pharmaceutical papers, although advertizing to the analyses, have been apparently terrorised into largely ignoring them through fear of offending their advertisers. This is not so much to be wondered at, because the modern Mæcenas is the patent medicine man, and, as some £1,500,000 is spent by those people on newspaper advertising every year, they are patrons too good to be irritated.

As there is this difficulty in getting knowledge of the composition of the quack remedies into the hands of the public by the ordinary newspaper channels, the Public Health authorities must take the matter up, and expose them in the police courts. Thanks to

the analysis by the British Medical Association, on the one hand, and to the action of Dr. Hope at Liverpool on the other, the matter is made comparatively simple. It will not be difficult to prove that it is the duty of any Public Health Authority, under the Food and Drugs Act, or otherwise, to prosecute persons selling worthless articles as cures for disease. The local analyst, with the results of the British Medical Association's analyst before his eyes, will have his difficulties greatly lessened and his results corroborated. The Medical Officer of Health can usually testify to the worthlessness of the article for the purpose for which it is sold. Should either of those officials be threatened with prosecution by the patent medicine people, they will be defended from damage out of the public funds. After a few prosecutions have been successfully brought, and the results published in the Public Report of the Sanitary Authorities, other councils will quickly follow suit.

The indications for the treatment of the quack medicine trouble are, then, to get statutory powers to insist that the ingredients be set forth on the label—and pending legislation to that effect to have the various Medical Officers of Health to deal with the makers under the Food and Drugs Act, with the help of the analytical records of the British Medical Association. The Association might well help the campaign by other means—namely, by furnishing chemists with printed results of the analyses of the nostrums on which most of the public money is being spent at the moment. These should be sent out under the authority of the Association, otherwise they would surely be questioned by the quacks. In addition to chemists, this might also be distributed to all doctors in the country, whether members of the Association or not, as well as to Public Analysts and members of the sanitary authorities and the clergy.

Nothing requires to be done but to distribute the reports of analyses which have already appeared in the *British Medical Journal*; these could not be improved upon. Thus in a single issue, at pages 32 and 33 of this year's volume, we find that analyses of at least three patent medicines out of which large fortunes have been made. Of one of these, the sale is claimed to be six million boxes per annum—and the constituents, according to analysis, aloes, ginger, and soap. The cost of the ingredients is said to be an eighth of a penny a box, and the cost to the consumer 13d. for that amount. The full account runs thus:—

#### BEECHAM'S PILLS.

Prepared by Thos. Beecham, St. Helens, Lancs. Price 1s. 1½d. per box, containing 56 pills.

These pills are very widely advertised in a variety of ways. The following is a specimen of the statements made:—

"Ordinary medicines begin at the wrong end, only correct symptoms. People take headache powders for headaches, blood medicines for the blood, and nerve remedies for nervousness, when they only need Beecham's Pills to tone up the digestive organs, the liver and the kidneys, and so keep the whole system in a healthy condition."

In a circular wrapped round the box it is stated that:

"These renowned pills are composed entirely of MEDICINAL HERBS, and are warranted free from mercury or other poisonous substance. . . . Persons of a strong or average constitution, but who may be temporarily suffering from any of the complaints herein mentioned, will usually find the dose to suit them to be three or four pills once a day; sometimes, however, it is necessary to repeat this dose morning and night, according to the condition of the system at the time. No harm can be done by increasing the dose where it is found insufficient, as the Pills can never act injuriously. Others, who may be frequently subject to one or more of the specified ailments, should take smaller doses of the pills occasionally, one, two, or three generally being the ordinary dose, which may be increased at discretion by the patient."

The "complaints herein mentioned" include Constipation, Headache, Dizziness or Swimming in the

Head, Wind, Pain, and Spasms at the Stomach, Pains in the Back, Restlessness, Insomnia, Indigestion, Want of Appetite, Fulness after Meals, Vomitings, Sickness of the Stomach, Bilious or Liver Complaints, Sick Headache, Cold Chills, Flushings of Heat, Lowness of Spirits, and all Nervous Affections, Scurvy and Scorbutic Affections, Pimples and Blotches on the Skin, Bad Legs, Ulcers, Wounds, Maladies of Indigestion, Kidney and Urinary Disorders, and Menstrual Derangements.

The pills had an average weight of  $1\frac{1}{4}$  grains. Analysis showed them to consist of aloes, ginger, and soap; no other medicinal ingredient was found. The quantities were approximately as follows:—

Aloes, 0.5 grain.  
Powdered ginger, 0.5 grain.  
Powdered soap, 0.18 grain.

In one pill.

Estimated cost of ingredients for 56 pills, one-eighth of a penny.

It is to be noted that a certain carefulness of claim as to the definite curing of a definite disease is to be observed in some of the more modern advertisements. Thus, certain nostrums claim that they have cured rather than that they "will cure"—but probably any magistrate would hold that there was a sufficient offer to cure. Another largely advertised pill is thus described by the analyst to the British Medical Association, page 32, 1909:—

#### DR. WILLIAMS' PINK PILLS FOR PALE PEOPLE.

Sold by the Dr. Williams Medicine Company, 46, Holborn Viaduct, London, E.C. Manufactured in the United States of America. Price 2s. 9d. per box, containing 30 pills.

These pills are advertised for a great variety of diseases, prominence being usually given to one disease in each advertisement; thus four long advertisements appearing simultaneously in different papers are respectively headed:—

"Afraid of being touched. So sore with Rheumatism. A once-crippled victim tells how Dr. Williams' Pink Pills cleansed his system of Rheumatism."

"Eczema expelled. Mr. John Chamberlain tells how his sufferings from Skin Disease were cured by Dr. Williams' Pink Pills."

"Sciatica's Swift Pains rendered this Lady helpless. Her case had defied treatment, but Dr. Williams' Pink Pills succeeded by curing the cause of Sciatica."

"The Dark Days of Dyspepsia. . . . Dr. Williams' Pink Pills go to the very cause of the mischief."

Each includes a long description of a "case," usually with a picture. The following is from the concluding paragraph of the first of these advertisements, and the others end in a similar way:—

#### "THE DR. WILLIAMS' WAY.

"When the muscles and nerves are tortured by poisons in the Blood, be the result Rheumatism, Sciatica, or Lumbago, the only way to a cure is to Enrich and Purify the Blood. Dr. Williams' Pink Pills, in this way alone, have cured not only Rheumatism, but Anæmia, Indigestion, Palpitations, Influenza's After-Effects, Eczema, Sciatica, St. Vitus' Dance, Spinal Weakness, and many forms of Nervous Disorders dreaded by men; also the special ailments of women."

In a circular enclosed in the package it is stated that

"The success of this remedy lies in the recognition of the controlling influence of the blood over the health of the body. It is the root of disease that must be attacked, and the most important development of modern medical science has been in discovering that, in most diseases, this lies in the condition of the blood. If the blood is thin and poor, the nerves cannot receive their proper nourishment, the system becomes run-down, and in a condition to invite disease. Build up the blood, restore the worn-out nerves and you remove the cause. Dr. Williams' Pink Pills for Pale

People contain elements necessary to give new life and richness to the blood.

"GENERAL DIRECTIONS:—Before beginning to take these Pills, cause the bowels to be freely opened by laxative or purgative medicines. . . . It is best to begin with one of Dr. Williams' Pink Pills after each meal, commencing the use of the medicine after a mid-day meal. Being stimulating, it is best not to take them on an empty stomach.

After taking for a few days, the number may be increased to two Pills at a dose, while in severe cases three may be taken at a time."

The pills were ovoid in shape and coated with sugar, coloured pink; after removal of the coating they had an average weight of 3 grains. Analysis showed them to contain ferrous sulphate, potassium carbonate (these two having reacted more or less completely, and about one-third of the iron having become oxidised to the ferric state), magnesia, powdered liquorice, and sugar. Since it has been stated that these pills contain arsenic, careful search was made for it, but it was not found. The pill is thus merely one of the many variations of Bland's pill. The quantities of the different ingredients found indicated the following formula:—

Exsiccated sulphate of iron, 0.75 grain.  
Potassium carbonate, anhydrous, 0.66 grain.  
Magnesia, 0.09 grain.  
Powdered liquorice, 1.4 grain.  
Sugar, 0.2 grain.

In one pill.

Estimated cost of ingredients for 30 pills, one-tenth of a penny.

Every practitioner finds that almost every patient who goes to him with gastric ulcer, or even cancer of the stomach, has been persuaded by quack advertisements that she is only suffering from indigestion, and, in fact, the patient has almost invariably spent a considerable sum of money on such remedies for the supposed ailment. One of the nostrums responsible for spreading the belief that almost all ailments are due to indigestion is thus described in the same number of the *British Medical Journal*:—

#### MOTHER SEIGEL'S CURATIVE SYRUP.

Proprietors, A. J. White, Limited, New York and London. Price 2s. 6d. per bottle, containing 3 fluid ounces.

Although this is described on the wrapper as "for dyspepsia," so many disorders are stated to be due to this cause, and amenable to treatment with this preparation, that it may fairly be included here. On the other side of the wrapper it is called "A cure for impurities of the blood" and "A cure for dyspepsia and liver complaints." In a circular enclosed with the bottle it is stated:—

"The symptoms mentioned above are the smoke of the fire of indigestion—a fire that will eat out your very vitals and sap your strength and vitality. For it can't be too often repeated that indigestion is the root of a great deal of evil, the origin of a great many disorders which no man quite understands how he came by. And why this is can easily be explained. Disease is poison; its symptoms are the manifestation of the poison. Indigestion creates many dangerous poisons, and is therefore the cause of many diseases.

"So let us get rid of the smoke by putting out the fire, and purify our blood and system with Mother Seigel's Syrup, which will sweep away the poisons and make us healthy and strong.

"Mother Seigel's Syrup is a highly concentrated, purely vegetable compound, having a specific action on the stomach, liver, and kidneys."

The directions on the label are:—

"Shake the bottle so as to mix the sediment. Commence by taking 10 or 15 drops three times a day in a little water. If this does not give relief, the dose may be increased to 30 drops."

Analysis showed the presence of free hydrochloric acid, tincture of capsicum, a bitter substance agreeing in its properties with aloes, and sugar (partly as invert sugar); the colouring and flavouring substances also present indicated that the sugar had been added

in the form of treacle. Quantitative determination of those ingredients capable of it, and estimation of the others by comparison with known mixtures, indicated the following formula:—

Dilute hydrochloric acid B.P., 10 parts by measure.

Tincture of capsicum, 1.7 parts by measure.

Aloes, 2 parts.

Treacle, 60 parts.

Water to 100 parts by measure.

Estimated cost of ingredients for 3 fluid ounces, one-third of a penny.

## THE RELATION OF HEALTH TO INDUSTRY. (a)

By B. A. WHITELEGGE, C.B., M.D., B.Sc.,  
F.R.C.P.,

H.M. Chief Inspector of Factories.

THE first portion of the address dealt with the pioneer work of Mr. Turner Thackrah, a Leeds surgeon, who, in 1831, wrote a monograph on the effects of various trades and occupations upon health. After describing many of the reforms and discoveries that had been made since that time, Dr. Whitelegge proceeded:—

Formal inquiries by committees have rendered signal service in the same direction. There have been many such, and one recent example will suffice. In certain branches of the great textile trade of Lancashire, cotton, the question of humidity had long been in serious dispute between employers and employed, and after endless unsuccessful attempts to arrive at a solution in other ways, a committee was appointed. It comprised chosen representatives of both parties concerned, and also scientific experts, with Sir Hamilton Freer Smith as chairman. The outcome of exhaustive inquiry and discussion was a unanimous report, which promises to solve the question, although certain details are reserved for further experimental research. In bygone years humidification had been carried to excess, and special legislation became necessary, the effect of which had been to secure not only limitation of humidity, but also a high standard of ventilation where humidification is practised. Nevertheless, the operatives continued to protest against humidity, and although statistics failed to show any evil effects in the way of disease or death, it was felt that something was wrong. That something proves to be the wet-bulb temperature, which the present law allows to reach a point at which the body temperature rises, so that health suffers, though without necessarily giving rise to any named disease.

Upon municipalities and other local authorities, and Medical Officers of Health, rests the primary responsibility for sanitation in home work, in workshops, and in some respects in factories also, and as an old Medical Officer of Health, I am gratified to realise how much is being done in that vast field. Recently the Home Secretary had occasion to appeal for assistance in the investigation of a question of national importance, the effect of the employment of married women upon their health, and that of their children, and the response from Leeds and many other of the great industrial centres was prompt and effective.

Another important responsibility which local authorities share with architects, builders, and, of course, owners, is that of seeing to the initial fitness of buildings for the purpose for which they are intended, and as regards factories many questions arise which can be settled with least trouble and expense at that stage; not only soundness of construction (especially where heavy machinery is to be fixed), means of escape from fire, lighting, drainage (not forgetting trade effluents), sanitary accommodation, lavatories, cloak-rooms and mess-rooms where the Act requires them, but also such details as the choice among materials and coverings of floors and walls (having regard to the requirements of the Factory Act as to cleansing), the slope and drainage of floors where wet processes are to be carried on, warming, ventilation, and exhaust where dangerous dust and fumes will have to be dealt with. The Arsenic Commission a few years ago found that

arsenic in the fumes of certain kinds of fuel used in the curing of malt condensed upon beams and rafters of malt-kilns, and at intervals fell back into the malt. It was in no way necessary to have these lodging-places, but no care had been taken to avoid them, and they had been provided even in kilns of recent construction. Similarly in new factories costly alterations have sometimes had to be made because statutory requirements as to means of escape or sanitary accommodation had been overlooked when the plans were settled. It is a matter for regret that few towns have formulated their requirements as to means of escape, in small factories, in the shape of bye-laws which they have power to make.

The State is indebted to many Medical Officers of Health for important investigation into the effect of local industries upon health. They supplement the broad statistics of the Registrar-General with the advantage of intimate local knowledge of the industries in question, and of the conditions under which each process is carried on.

There is one pitfall in connection with industrial statistics of accident and disease which may easily lead to error—namely, the widely different conditions in occupations that pass under a common name. Nearly every named trade is in reality a complex of different processes, the dangers of which are not necessarily equal or even of the same kind. Pottery, for example, includes many different kinds of manufacture, and of processes in each. Some of the latter are dusty, some are poisonous, and in varying degree; some are intermittent, others continuous, and some entail exposure to high temperatures. Some of the dangerous sort are carried on with all reasonable precautions, which may be neglected in others. Perhaps I may put my point most simply in the language of low mathematics, vulgar fractions. Given a true numerator, in the shape of a complete record of cases of illness or death attributable to the occupation, with any necessary qualification as to extraneous causes outside the factory, we still need a true denominator in order to arrive at any sound statistical conclusion as to the rate of incidence. That denominator cannot be the total number of potteries, for they vary in size and in the risks incurred. Nor can it be the total number of persons employed therein, for not all are exposed to danger. We come nearer to the true denominator when we take the numbers employed in a given process, or exposed to the danger in question, but even this is not altogether precise or conclusive by reason of other factors I have mentioned. As a rule the most trustworthy rate is that calculated for a unit process or kind of employment, with corresponding limitation of both numerator and denominator, and even then varying degree and duration of exposure to risk may affect the result, not to mention varying degrees of susceptibility according to age and sex.

If phosphorus poisoning in the match industry had been so common as to warrant statements in the form of incidence rates, the calculations would be further complicated by the consideration that necrosis is practically unknown in the first few years of employment in phosphorus processes.

When all necessary structural provision has been made, it rests with the occupier to see to the administrative maintenance of efficiency, by watchfulness, and where necessary by occasional rehearsal. We have records of elaborate outside staircases for escape in case of fire, ending outside a window which would not open, or was not distinguishable inside from other windows; and of emergency exits which were blocked and rendered useless by storage of goods. An occasional rehearsal, such as is arranged in many works, would at once reveal defects of this kind. Appliances for first aid, for instance in gassing, are of little avail unless there are men at hand who know how to use them. Exhaust ventilation is dependent upon the ducts being kept clean, and that can only be secured by systematic inspection.

In recent years we have tried to get into closer relation with the industries and administration abroad; we have already learned some useful lessons from them in the way of safeguarding employment, and I hope we have given something in return. In one respect in

(a) Abstract of the Presidential Address in Section of Industrial Hygiene, Leeds Health Congress, July 22nd, 1909.

particular they are ahead of us. In several industrial centres—Berlin, Milan, Amsterdam—I have seen well-organised permanent local exhibitions of safety appliances, where an employer wishing to examine the latest improvements in detail of that kind can find them and study them. There are attendants ready to explain anything that needs explanation, and to give practical demonstration if need be. Similar arrangements have been made at Paris, Vienna, Munich, and elsewhere. In this country it is true that we have exhibitions of machinery and appliances, on a permanent footing, or simply as part of a temporary trade exhibition; but in these, important and useful as they are, fencing finds little recognition, and many of the exhibits, admirable in other respects, present quite unnecessary points of danger, defects which are obvious and will have to be remedied at increased cost and less conveniently, as soon as the Factory Inspector sees them in a factory. Indeed, the purchaser will be breaking the law if he takes them into use as they stand. Nor does the omission become any more reasonable when it is remembered that the same makers often make the same machinery for export to foreign countries or to India without forgetting the fencing. In such cases, however, the contract requires it, and home contracts need not be less explicit.

Where an important industry, entailing risk of accident or injury to health, is localised, such an exhibition would be of permanent interest and service, and I am optimistic enough to hope that something of the kind will be instituted, for instance, in the great textile centres and in those of the metal and mining industries, and in the Potteries. Meanwhile, it is not easy to find any satisfactory answer to the question which was put to me at each of the foreign cities I have named: Why is it that the United Kingdom, with its enormous industrial population and vast yearly records of industrial accidents and disease, has nothing to show in the direction of practical demonstration of means of safety, other than the actual installations on individual private premises? As matters stand, employers who desire to adopt the best precautions often go to unnecessary cost in ineffective installations, and no one realises more fully than I do the unwieldiness of blue books as a source of information, in comparison with a definite working visible example of things as they should be.

Take the case of a new factory in which a dangerous dusty process is to be carried on, and exhaust ventilation is required, and it is proposed to effect it by means of fans. Somebody has to decide upon the kind of fan, its size and speed, its position, the calibre, direction and arrangements of main and branch ducts, the position, construction and hooding of the exhaust opening so that it may carry away the dust most effectively with least interference with work, and as near as may be to the point of origin. Counter openings, to admit air into the room, are necessary, and in some cases where hoods are inconvenient, the removal of dust can only be made complete by providing also a slight plenum draught blowing past the source of dust into the exhaust opening and thus confining its supply to the dust-laden air. Then the disposal of the dust has to be considered; whether it shall be allowed to settle in a dust chamber, or arrested by filtering the air through canvas screens or bags, or by a water surface or spray, or whether, on the other hand, it shall be simply discharged into the open air for the public benefit, possibly to be blown in again at the windows. If the employer is wise, he takes expert advice in such matters and follows it; but too often it is assumed that the question is simply one of fan or no fan, and costly mistakes result. If the dust is heavy and discharged with force, as in grinding, it is not easily deflected from its initial course by air currents, and it has to be intercepted before it can be carried off, but so far not much advance has been made on the lines indicated long ago by Overend, that is in the way of harnessing the tangential discharge of dust and the wind of the grindstone, and turning them to account in the removal of the dust.

Metal grinding is only one of the great industries of the country in which dust is a grave danger to the health and life of the operatives. And yet we may look in vain even in the centres in which those indus-

tries are carried on, for any working model accessible to the public by way of demonstration of what can be done. In these matters we move slowly, and the practical application of the great advances made in recent years as to removal of dust and fumes is delayed accordingly.

Safety appliances of all kinds, safe modes of construction, and means of ventilation, could be illustrated more convincingly by practical visible example of the kind than by precept. We have now several standards of ventilation, in terms of carbonic acid or delivery of air or velocity of draught, standards of humidity, and of soluble lead. It is surely desirable that employers and workmen should have the opportunity of learning how these are applied, by what methods and appliances the determinations are made, and what simple tests can be carried out without costly appliances or expert knowledge. We all know when a chimney smokes, and need no chemical or anemometric tests to assure us that it is really smoking, but it does not seem to occur to anyone that an exhaust intended to carry away fumes or light dust can readily be tested in the same simple way; if smoke is applied and eddies about in the hood and escapes from the edge, the draught is not efficient, whatever the anemometer may say.

I have intentionally laid stress upon dust and dust prevention for the reason that their importance has until recently hardly received sufficient recognition. Take for example the pottery industry, which has long been regarded as a dangerous one, and is now being thoroughly studied afresh by the Departmental Committee, over which Sir Ernest Hatch is presiding, with the assistance of representatives of the employers and employed, and other experts. Lead poisoning is a terrible evil, in great measure preventable; something like three-quarters of that which prevailed twelve years ago has in fact been prevented, and the reduction will go further. But there is a still greater evil, equally preventable, against which we have for years been contending with some success, namely, the phthisis or "potters' rot," due to inhalation of dust. Of this the public hear comparatively little. Though more serious it is perhaps less dramatic than lead poisoning; there are no quotable figures of disease, and those of death only after the lapse of years in the invaluable decennial records of the Registrar-General. The same mischief arises in many other industries, and hence our campaign of recent years for the suppression of dangerous dust, by means of exhaust ventilation, enclosed apparatus, substitution of wet processes for dry. It has to be remembered too that much of the lead poisoning arises from inhalation or swallowing of dust containing lead.

Adequate lighting is one of the important factors in industrial efficiency, although the Factory Acts have little to say about it. Even as regards daylight there is something to be learned from the experience of schools, and the use of artificial light raises further questions as to its quality as well as its intensity, its actinic value and the part of the spectrum to which it belongs. Something more definite than the vague terms good and bad lighting is wanted for practical purposes, and it should not be impossible to arrive at data fixed by actual measurement of a precise kind, whether by photometer, spectroscope or otherwise.

As to temperature, measurement is familiar and simple, or at all events it is thought to be so, but there is much to be taken into account beyond the reading of the thermometer. The reading varies with position in the room, with degree of exposure to radiant heat, as well as temperature of the air in general and currents of air in particular. For sedentary employment, not requiring much exertion, it is held that the temperature should not be below 55° F. With regard to the upper limit, it has long been known that work can be carried on at extraordinarily high temperatures without apparent ill-effect, but the recent report of the Humidity Committee brings out the important qualification that all this is contingent upon dryness of the air, and that the wet-bulb temperature is the true danger signal.

There is a wide and important field for physiological and anthropological measurements of the kind

now being adopted in schools, and examples more closely connected with industrial conditions are to be found in the investigations made by Dr. Legge and Dr. Collis in the course of inquiries into certain of the dangerous trades. Research of a similar kind might usefully be directed to the question of fatigue, as determining the optimum duration of continuous spell and daily and weekly hours of work in the more arduous kinds of employment—those requiring alertness, concentration of attention, as well as sustained physical effort. For some determinations of the kind little beyond mere counting would be required. The Factory Acts allow for women a continuous spell not exceeding  $4\frac{1}{2}$  or 5 hours, and 10 or  $10\frac{1}{2}$  hours a day. Is it, or is it not, the fact that beyond a certain point within those limits attention slackens, threads are dropped more frequently, and the effective output per hour is lessened? One would anticipate that in some kinds of occupation the answer would be affirmative, and no doubt there has been in practice rough adjustment of hours accordingly. Even as regards men, whose hours are not limited by statute, the point is sometimes of grave importance, as witness the records of signal-men employed for excessive hours on emergency, and in places under the Factory Acts the same question occasionally arises, notably in connection with men in charge of cranes and other lifting appliances, upon whose watchfulness the safety and life of others may depend.

The welfare of the operatives in certain industries is affected by demands on the part of consumers, and in saying this I do not refer so much to allowance of reasonable time even in such high things as dress-making and millinery, as to the choice among articles equally suitable for the intended purpose. Reverting once more to pottery for an example, some kinds of ware can be made without lead, and others with limited use of lead, but this is further dependent upon the tint and decoration required, some of which entail increased use of lead for that purpose alone. As another example a large section of the public grew accustomed to phosphorus matches, with their familiar smell and manner of striking, and entertained doubts whether others were so good, or would keep, or resist damp. Experiment on these points were reassuring, but the demand for the old kind of matches continued, and it was not until the match manufacturers agreed unanimously to the prohibition of phosphorus, coupled with prohibition of import, that the Government were able to put an end to this needlessly dangerous branch of industry. In other countries the task was easier; in some the manufacture of matches was a Government monopoly, and in others the use of safety matches which entail no risk of the kind, was general.

Here I must stop, leaving untouched many branches of our subject upon which I should have wished to dwell had time permitted.

## OPERATING THEATRES.

### ST. THOMAS'S HOSPITAL.

**OPERATIONS FOR RECURRENCE OF CARCINOMA OF THE BREAST.**—MR. EDRED CORNER operated on a woman, æt. 55, for recurrence after operation for carcinoma of the breast. The original operation had been done about a year before. At it the breast, the sternal part of the pectoralis major muscle, and the whole of the contents of the axilla had been removed. In order to do this last step thoroughly, the skin of the axilla had been turned down as a flap by means of an incision backwards from the original wound; the result of this was that a more or less tri-radiate scar had resulted. If this scar is examined, Mr. Corner said, it will be seen that all three limbs show the thin, clear scar resulting from union by first intention. Where the three straight scars unite it is seen that union has not been by first intention. After the original operation the tips of the triangular skin flaps necrosed and separated, leaving a small place, perhaps an inch in diameter, to granulate; so that in this case there is

the scar of an operation done for malignant disease, nineteen-twentieths of which healed by first intention, and one-twentieth did not. It is remarkable in these circumstances that the recurrence which appeared a year later showed itself in the one-twentieth, which healed by second intention, there not being a trace of any recurrence in the nineteen-twentieths which healed by first intention. Of course, it may be that a fragment of the original tumour was left behind at the very spot where the three straight scars joined, where healing was by second intention. The recurrence itself consists of three small nodules. From the character of this recurrence and of the original operation it is very improbable that fragments of the growth were sown only in this part of the wound and not in any other. Rather it is more probable that fragments of the growth were left or sown in other parts of the wound. But where the healing was by first intention, the fragments have grown slowly, never being apparent or even having disappeared, so that recurrence is either not apparent or has not occurred. In the region of the wound, where healing was other than by first intention, the fragments of the growth which were implanted there have grown and become apparent. This case, he thought, shows most clearly the great influence which primary union or suppuration has on the success or failure of surgery in operations for the removal of malignant disease. Mr. Corner then dissected away the recurrent nodules and sewed up the wound.

Another patient was operated on by Mr. Corner for recurrence of the growth after removal of carcinoma of the breast, the recurrence in this patient being behind the clavicle. It is important, Mr. Corner said, to avoid recurrence in this situation, as it occurs beyond the field of the original operation, hence it is not a recurrence in the true sense of the word, the growth being there at the time when the original operation is done. The clinical interest of this case, he remarked, lies in the fact that recurrences in this situation are often said to be inoperable, and by the time that the glands above the clavicle have become sufficiently enlarged by the growth to be recognisable, infection of the mediastinal glands must also have occurred; nevertheless, he has often removed malignant glands above the clavicle with benefit to the patient, the patient living some years more. Moreover, it is much better for the patient to die, if she is going to die, than to live the remainder of her days with the presence of an obvious and increasing tumour to distress her, hence it is advisable to remove these recurrences wherever it is possible.

The space above the clavicle is a difficult and dangerous situation in which to operate, because of the presence of many large vessels, nerves, and lymphatics, and because the operation has to be conducted in a deep chasm behind the clavicle. But these cases are desperate ones, and necessitate that an extensive and thorough operation should be done amongst dangerous surroundings, hence he would advise that the middle half of the clavicle be removed and not replaced: this allows of the operation being done easily and successfully without injury to the vessels, nerves, and lymphatics or pleura.

Mr. Corner then turned down a flap of skin from over the clavicle and the lower part of the neck; the attachments of the muscles to the clavicle were then divided, defining the bone. Mr. Corner then explained that it was advised in order to remove the clavicle to begin by disarticulating its internal end from the sternum, but he had found this troublesome, and he preferred to saw partially through the clavicle at its inner and outer part, completing the division of the bone with bone forceps. This procedure he had found quicker and accompanied by less hæmorrhage than the complete removal of the clavicle by disarticulation. The detached part of the clavicle was then removed, and the subclavian vessels, pleura, and brachial plexus exposed. Two enlarged glands were seen and easily dissected away. All bleeding vessels were then tied and the skin wound closed in the usual manner.

Healing took place by first intention, and it was extraordinary how little the movements of the shoulder were affected by the loss of the middle half of the clavicle.

## CORRESPONDENCE.

### FROM OUR SPECIAL CORRESPONDENTS ABROAD.

#### FRANCE.

Paris, Sept. 19th, 1909.

##### BANTI'S DISEASE.

THE disease or syndrome of Banti presents special characters which distinguishes it from other cases of splenomegalia. It is particularly chronic in its manifestations, and recognises three periods. The first period is characterised by two symptoms, enlargement of the spleen and anæmia. The spleen may attain very large proportions, invading the iliac fossa but preserving its form. The surface is hard and smooth, while the tumour is absolutely indolent. It is thus that the nature of the disease is frequently discovered by chance, in the course of examination.

The second great symptom is anæmia: the patient is pale, out of breath, presents cardiac souffles, and the number of red corpuscles as well as the amount of hæmoglobin is diminished. At this period the liver is of normal size and works well.

This condition is generally very long, running through two, three, or even five years. At the end, abundant hæmatemesis may set in, compromising the life of the patient. The second period is shorter and presents as principal symptoms a decrease in the diuresis and an increase in the volume of the liver, provoking gastric disturbance, dyspepsia, and hæmorrhoids.

The third period is marked by the presence of ascites due to atrophic cirrhosis of the liver. After one or two evacuations of the liquid by tapping, the general health is affected; gastro-intestinal hæmorrhage appears, as well as epistaxis and purpura, and death comes on from hepatic insufficiency. The duration of this period does not exceed eight months.

As to the mode of development of this malady opinions are divided. MM. Gilbert and Lereboullet consider the malady of Banti as belonging to the class of hypersplenomegalic cirrhosis. From the beginning the liver is at fault, while the enlargement of the spleen is consecutive to the alteration of the liver. M. Chauffard, on the contrary, sustains the existence of Banti's disease: for him the lesion of the spleen is primary, secreting noxious products which reach the liver through the splenic and portal veins provoking consecutive cirrhosis. This idea has the advantage of being verified by experimental research.

As to the treatment, it may be said at once that Banti's disease can get well even when abandoned to itself. In such cases the treatment might be limited to the secondary symptoms: the hæmorrhage and ascites when necessary, while cod-liver oil and arsenic may be given for the general health. Injections of atoxyl up to two grains every second day, have been tried with success. Mery recommends injections of cacodylate of soda. Surgical treatment has been recommended, the spleen has been removed at an early date and before hepatic cirrhosis set in. Banti furnishes 16 cases thus treated and which recovered, while Harris and Herzog give statistics of 19 operations, of which 14 were successful.

##### PYURIA.

The presence of pus in the urine is revealed by different characters: purulent streaks or filaments, coming generally from the urethra and composed of an agglomeration of leucocytes in a magma of epithelial cells; a cloud of flakes which deposits on standing, or a general cloudy aspect with an increase in the quantity of urine indicating a renal origin.

Divers causes, however, may lead to believe in the presence of pus, when in reality it does not exist. Such, for instance, is spermatorrhœa, which may possibly pollute the last drops of urine or filaments due simply to epithelial cells or spontaneous fermentation of the urine. To avoid these errors, the practitioner should have the patient urinate in his presence. Another great cause of error is the presence of urinary sediments. The patient should be asked to state if the urine was clear on emission, and only gave a deposit on cooling (urates), or if the emission was cloudy at

the outset (phosphates). By heating, the urates are immediately dissolved, and a drop of acid dissolves the phosphates. These experiments should never be neglected, as phosphaturia has a strong resemblance to purulent urine.

Where the presence of pus is correctly diagnosed, its origin becomes a matter of importance. Filaments indicate in general an urethral or prostatic origin. To distinguish between the anterior and posterior portions of the urethra, the patient is asked to urinate in three glasses; if the filaments come from the anterior portion the first glass alone will contain them; if from the posterior portion they will be found in the last glass.

In case of general suppuration, the quantity and its intermittence are of primary importance. If the deposit is abundant, the kidney is at fault, proving the existence of pyo-nephrosis, which may drag on for years. Intermittence is also a character of renal disease, as the bladder suppurates continuously.

Renal pyuria is frequently accompanied by vesical symptoms (frequency of emission and pain), but sometimes it is necessary to examine whether the bladder or the kidney is at fault.

In the case of the bladder the deposit is less consistent and more constant, while the organ is sensitive to the touch, to the passage of a catheter, or to distension; where the kidney is diseased the bladder is not sensitive, the corresponding ureter is increased in volume, swollen at its vesical orifice and painful, while the cystoscope shows inequality between the two vesical orifices. Catheterisation of the ureter confirms the diagnosis. Where the two kidneys are diseased, polyuria is abundant, the general condition of the patient is bad, and fever persists in spite of a catheter à demeure.

The causes of the affection may throw some light on the subject. Suppuration can be provoked by ascending gonorrhœa or by the use of a septic catheter; in such cases the idea of tuberculosis should be eliminated. On the other hand, where the patient affirms that neither of these causes were possible, presumption of tuberculosis is warranted. Bacteriological examination will clear up any doubt.

The treatment is that of the cause. First of all an exclusive milk regimen should be proscribed; it does no good and tends to weaken the patient, who requires all his strength to struggle against this depressing affection. Santal is of use, and certain antiseptics, as benzoate of soda, urotropin or helmitol, while waters as Contrexéville, Evian or Vittel are to be recommended. Where medical treatment fails, recourse should be had to the usual surgical operations.

#### GERMANY.

Berlin, Sept. 19th, 1909.

##### VERONAL AND VERONAL-SODIUM.

In the *Deutsche Med. Zeitung*, No. 68/09, Dr. Alfred Katzenstein contributes a note on the above-named preparations. The latter has been more recently introduced by the original producers of veronal, as in some respects a more perfect preparation. It is distinguished from the older drug by greater solubility, and perhaps a more disagreeable taste. Veronal requires 150 parts of cold water, whilst veronal-sodium is ten times as soluble requiring only 15 parts of water for its ready solution. Its solubility renders it much more prompt in action, and from its being more readily parted with the feeling of heaviness on the morning after taking it is said to be less marked. The writer gave the two preparations alternately to the same patient, and had also varied the two in other cases. His conclusions were that the disagreeable taste of the veronal-sodium was complained of, and that it was not disguised by covering tablets with chocolate. In general, however, the sodium compound was more prompt in its action owing to its greater solubility. On this ground he made some distinction in regard to the administration of the two preparations. There are as is known two forms of sleeplessness: one in which the patient cannot get off, but who sleeps soundly when once he has fallen asleep; and the other in which the patient falls asleep readily, but

awakes in the early hours to toss restlessly about the bed until the morning. In the first form he considers veronal to have the preference, whilst in the latter he considers the sodium combination to be preferable on account of its more prompt action. Here in the night the veronal difficulty—solution of the veronal—is dispensed with, whilst the sodium tablets are readily dissolved in the glass of water at the bedside. People who are nervous and bad sleepers will find the sodium combination useful on journeys, in hotels, and for the sleepers in trains, but the medicine must, of course, be taken some little time before going to bed. In general he recommends that veronal should be taken in hot tea, but he also finds that it is well taken in an effervescing drink, and aerated waters. In the case of veronal he puts the powder on the tongue and washes it down with the liquid, but with sodium-veronal it is best to dissolve it in the liquid before giving it.

#### THE DEMONSTRATION OF BACTERIUM COLI IN WATER.

The Institute for Hygiene, Berlin, gives a report on this matter (*Arch. f. Hygiene*, 70/4). By means of precipitation and inoculation of the precipitate on a nutrient medium colon bacilli may be shown to be present in water when there are no more than 7 colonies to the litre. On Drigalski's medium the colonies, 2 to 6 mm. in diameter, are a bright red and not transparent; dark red colonies are also met with. On the nutrient medium of Endo the colonies are intensely red, sometimes with a green shimmer on the surface like fuchsine crystals. The process of precipitation and inoculation does not require any elaborate laboratory arrangements, and gives a positive result within 20 hours. When one is thinking only of the colon bacillus the typhoid bacillus may sometimes be stumbled on.

#### THE FOUNDING OF HOMES FOR MOTHERS A SOCIAL DUTY.

In the *Vierteljahrsschr. f. öffentl. Gesundheitspflege*, 3/09, Dr. Gradenwitz of Breslau pleads for the foundation of mothers' homes, especially for those unfortunate females of the middle classes who are about to become the mothers of illegitimate offspring, as it is this class especially who both morally and psychically are in the greatest need of protection. He claims that it is a national duty to take care that all the children in such cases should come into the world in a condition of good bodily health, and that they, along with the mothers, should enjoy a long period of protection, lasting for months, if necessary, or during the period of lactation, so that a rational increase of the population may take place, and the great waste of infant life during the early months of life be prevented. The mortality amongst children during the first year of life is notorious and appalling, and the utmost should be done to prevent it. It is undoubtedly of the first importance to the State that children (young soldiers and their wives) should come into the world, that they should grow up strong and capable of military service, and nothing would be more likely to prevent the awful waste of infant life that is continually going on than the foundations the writer pleads for. As regards Germany alone, he observes the social necessity for the founding of such homes will become apparent to everyone when he becomes aware of the pitiful fact that 150,000 illegitimate children are born yearly in private houses in Germany. The writer, in conclusion, points to the good results that have been obtained in the mothers' homes that are already in existence.

#### AUSTRIA.

Vienna, Sept. 18th, 1909.

##### WASSERMANN'S SERUM REACTION.

THIS is a test for syphilis, recently introduced, that is still challenged for its reliability. It is performed with the serum and blood in a menstruum of glycocholate of soda, and is intended to supplant the complementary method which requires expensive apparatus and a considerable amount of labour to perform. Schwarzwald, in Prof. Sternberg's Klinik, comes forward with 302 cases which he has examined in different institutions, such as lunatic asylums and imbecile institutions, beside the hospital over which he presides. According

to Porges the reaction is "good, but not absolute, nor can it be accepted as a substitute for the complementary method." Bauer records 60 cases examined by the complementary method, 19 of which were positive, but the coagulation method gave only eight positive, two doubtful, and all the others negative. Fritz and Kren used lecithin instead of the glycocholate of sodium, but they consider the results more reliable with the latter. Of the 302 cases in question we may group them into different classes for the sake of convenience in defining the stages of the disease, such as tabo-paralysis, congenital syphilis, and Chiari's aortitis or meso-aortitis proliferans. All these had to be differentiated from tuberculosis, diabetes, scarlet fever, etc., etc. The positive reaction was observed within twelve or twenty hours, sometimes in large flakes, other times fine powder, either sinking to the bottom or forming a layer on the surface. The experiments were conducted with controls with sterilised physiological salts solution which remained perfectly clear. After the diagnosis had been completed and the history satisfactory, 65 were then found to have a real or suspicious character of syphilis, of which 41, or 63 per cent., gave a decided positive reaction, and 24 negative.

With these results Schwarz adds phenomenal changes which he cannot explain, and leaves it to the reader for the time being. In three cases the reaction was negative on the first trial, but after three applications of mercurial unctions and one month elapsing before the next test, gave a positive reaction. Another case, without unction, in the course of a month gave a positive reaction, which had been negative before.

#### TRANSPLANTATION OF ORGANS AND ARTERIES.

Garre has excited a good deal of criticism by the paper read at the International Congress on his experimental operations in transplanting blood vessels and attaching them by invagination. Payr had previously endeavoured to accomplish this by an aluminium prosthesis, but Karl, in 1905, introduced his so-called vascular circle loop, which was more secure and was readily adopted by clinical surgeons, while Karl has done it in animals. The transplanting of other organs, like the spleen, liver and bowel, has not yet been so successful, although he is hopeful and sanguine enough to believe in the transplanting of limbs. By this means the transplanting of an artery from one animal to another, or from an animal to a man were easily accomplished, and after 52 days the circulation was quite restored. Another experiment that proved successful in his hands was the transplanting of a part of a vein into an artery. It had always been feared that a vein would be too feeble or elastic to take the place of an artery, as it would probably distend and form a sac, but these experiments have disproved the fallacy, as the new vein inserted into the artery with high pressure, soon accommodates itself to the artery and performs the physiological function of the arterial vessels. This is a useful part of knowledge to the surgeon who may soon repair a torn artery from a suitable vein. On the transplanting of organs he had twice obtained two good results in dogs, where he transplanted the thyroid glands. Stich and Makks have also transplanted the kidneys with good results.

#### HUNGARY.

Budapest, Sept. 18th, 1909.

##### THE PRESENT STATE OF OPHTHALMOLOGY IN HUNGARY.

I AM privileged to send you the address delivered by Prof. Emil de Grósz, Secretary of the Sixteenth International Congress, President of the Ophthalmological Section.

"It is a great honour," he remarked, "for me to be allowed to preside, as chairman, over the meetings of the Ophthalmological Section of the Sixteenth International Congress. I experience strong emotions as I stand before you, gentlemen, the representatives of ophthalmological science all over the world, and feel that I must offer some explanation for the presumption of so small a nation as we Hungarians are in having invited the leading medical authorities of the greatest nations to make our modest home the scene of their

united efforts in the cause of medical science. On the occasion of one Congress the delegate of Sweden said that the tree of science grows in every soil if properly taken care of. I may with pride assert that the tree of ophthalmological science in Hungary is no weak sapling, but a strong, time-worn trunk, whose roots are deeply engrafted in our public institutions, and which has already produced blossoms, and even fruit. For this fact, too, we have you to thank; the Hungarian scholars practising in our science have endeavoured to ennoble the Hungarian tree of ophthalmology by grafting on it all that they have been able to learn from those nations who are the leaders in the work of civilisation. Every nation will recognise the traces of its influence on the development of our institutions, and if Boerhaave was called *Communis Europæ præceptor*, may we be allowed to aspire to the title of *Communis Europæ discipulus*?

"To-day the pupil bids hearty welcome to his masters in his unpretentious home. As I said, the tree of ophthalmological science in Hungary is time-worn. After that in the Vienna University, the chair of ophthalmology in the University of Budapest is the oldest, and the ophthalmological clinic No. 1 attached to the Royal Hungarian University of Budapest has been in existence for over a century. The ophthalmological hospital at Nagyvárad was established by my grandfather eighty years ago. A book written by a predecessor of mine in the chair of ophthalmology, *Fabini: Doctrina de morbis oculorum*, was, in the early years of last century, employed as a text-book in the Universities of Italy and Holland. And the *Journal of Ophthalmology*, the present number of which is dedicated to you, gentlemen, is already in its forty-sixth year.

"Consequently, as the modest inheritors of this tradition, we have had no other duty than to maintain this level of ophthalmological science. With your permission, gentlemen, I will proceed to give a brief sketch of the position of this branch of science in Hungary.

"In the University curriculum, ophthalmology is on a level with the treatment of internal diseases and surgery. Lectures on the subject must be attended for two semesters, ten hours a week; it is one of the subjects for the third "rigorosum" (viva-voce examination to qualify for degree of M.D.); candidates for the degree of doctor of medicine are obliged not only to show their clinical knowledge, but, at a special examination held for that purpose, to display their manual skill as operating surgeons. This year a second chair for ophthalmology was created in the Budapest University, and two new clinical hospitals with 80 beds, for the use of both chairs, have been erected. There is a new clinical hospital, too, with 50 beds, attached to the chair for ophthalmology in the University of Kolozsvár. Of recent years three State hospitals for diseases of the eye have been established, one at Budapest with 112 beds, one at Szeged with 78 beds, and one at Brasso with 87 beds. Besides these, there are three State hospitals for the treatment of trachoma, the transformation of which into general eye hospitals is imminent. In the Budapest hospitals there are six ophthalmological departments with 172 beds, and in those in the provinces 14 such departments with 457 beds; so that in all there are 1,239 beds in the country for patients suffering from diseases of the eye. The fact that during the past five years the number of such beds has increased by 390 is a very reassuring one, and there is every prospect of the work of development being continued.

"Besides offering facilities for effecting cures, the Hungarian State has done its best in the prophylaxis. The organisation of the fight against trachoma is already one of 25 years' standing. As early as 1886 a special Act was passed to check the growth of this disease, and to lead the work of overcoming the evil, the Minister of the Interior appointed a Government commissioner and a superintendent of public health, the former being a University professor, the latter a University lecturer (Privatdozent). These measures are the best proof of the fact that the State desires to employ the weapons of science in the battle against this disease. And the same fact is proved by the prize

offered by the Minister of the Interior for international competition, to be awarded to the best work treating of the ætiology of trachoma.

"Of our humanitarian institutions, the Institute for the Blind is of 80 years standing: not long ago it was transferred to a new building, and workshops have been erected for the employment of the blind adults.

"I have enumerated all these facts, not by way of boasting, but to explain our presumption in demanding our share in cultural activity of the greater nations. We are proud and happy that you have accepted our collaboration; we promise to be diligent fellow-workers, and shall never allow ourselves to forget that you are our masters.

"On the opening day of the Congress we greet you, gentlemen, with the respect and homage of pupils and younger brothers."

## FROM OUR SPECIAL CORRESPONDENTS AT HOME.

### GLASGOW.

#### THE NEW CANCER HOSPITAL (FREE), GLASGOW.

THE large extensions which were opened last week will form a valuable addition to this institution. The necessity for new hospital buildings has long been felt, for the experience of the last few years has shown that the existing hospital, which is about to be pulled down, is not suitable for carrying out the proper care of cancer patients. In saying this, there is no intention to cast any reflection on the judgment and thought bestowed on it when erected. At its opening it was spoken of as a well-equipped and well-planned hospital, and such it was as far as the money available and other circumstances would allow, but in practice it was found that it was not adapted for fully meeting the wants of the very varied class of patients that have to be admitted to a cancer hospital, and was quite inadequate to house the numerous staffs of the nursing and administrative departments of the hospital. The wing just completed is planned throughout on the lines of a modern hospital; the buildings, when completed, will comprise all the departments required for the treatment of cancer. Each room receives the maximum of light and air, and a flat roof has been provided where patients may exercise and be as much as possible in the open air.

For the accommodation of patients there are four large wards, each containing eight beds. A convalescent ward is also provided, and nine single wards, having a southern exposure; these will be used for patients requiring quiet and isolation.

All the sanitary annexes are contained in towers, which are entirely cut off from the wards, and are fitted with appliances of the most approved pattern. These apartments are all adequately heated, and various ingenious fittings and furnishings have been installed which will add materially to the comfort of the patients and the convenience of nursing.

The whole of the top flat of the north-east portion of the building has been ingeniously arranged as a research department. The light here is ideal, and the rooms have been carefully fitted up in a manner suitable for the work to be done. One of the objects for which the Glasgow Cancer Hospital exists is the advancement of the medical and surgical scientific knowledge of the disease, and in order to carry out such work properly and advantageously, fully equipped laboratories, staffed by a select body of workers, have been provided. The research department is located at the top of the hospital, with its chemical laboratory and other rooms, and will be found to contain all the needed accommodation.

The whole of the buildings are lighted by electricity and heated on the "Rock" system by means of radiators, each radiator being under direct control, so that the temperature of any portion of the building may be raised or lowered as desired. The patients will shortly be removed from the old portion of the

buildings into the new wards, and the older part will then be entirely rebuilt, bringing it into harmony with the new, and the directors hope to have the entire building ready for occupancy in six months.

## LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

### TUBERCULOSIS AND HEREDITY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—All praise be to Lady Aberdeen and those who work with her for the purpose of benefiting mankind by trying to eradicate, or even to mitigate, any one of the many diseases that afflict the human race. Let her ladyship and all others inculcate the benefits arising from fresh air, judicious exercise, good food, cleanliness, moderate recreation, mental and physical comforts, elevation of morals, and as many of all the other good things as constitute ideal perfection—and good will result in proportion to the extent to which these things can be realised. Let us suppose they can all be fully carried out. When they are, are we to have a world with happy freedom from disease? Are all the "ills that flesh is heir to" to be driven back, and once more shut up in Pandora's box, there to remain for ever? I assert that it is not going to be so. No doubt, if all these happy conditions were realised, many persons otherwise doomed would have prolonged lives in perhaps fair or good health. But I say there are many persons, and will be to the end of time, who would not be safe even if all the above desirable conditions were attained. Will supplying the lower classes with all that wealth can give remove certain diseases or protect those classes? Are the higher classes exempt from those diseases? Are not tuberculosis, insanity, and cancer rife in all classes? I assert that these diseases are hereditary, and that it is because they are hereditary that they are so universal; and I say that, being hereditary, there is something more to be done than sanitary science can do. Of course, I know that we are now told that tuberculosis is not hereditary—that it is only the tendency that is inherited. Well, what is a tendency? I won't stop to mince words, but I say there is *something* transmitted that develops into tuberculosis under conditions favourable to its action. It is useless to deny that certain diseases are hereditary, and that they do not "run in families" from generation to generation even though an individual or a generation may be passed over. It is useless to tell us that tuberculosis is only contagious and not hereditary, and that the members of an afflicted family only take the disease from one another. If so, where does the first of them get it? How do they send it on to the next generation if it is only contagious? Take a case the truth of which I myself can vouch for. A family of ten children were born to a country couple. These children scattered in early life to earn a living for themselves; some left home before the younger members were born, and there was never any communication between them; others went to America at different periods, and made out their living many miles apart; some went as domestic servants to different places in this country, while some few more remained at home. Some of the younger members never even saw the elder ones. Yet all these died of tuberculosis; some in America; some returned to die at home, but only to find that the rest were dead or dying from this fell disease. Does the theory of contagion explain this? The "man-in-the-street," with his well-known keenness in discerning facts, will join me in protesting. The fact is, that the father of this unfortunate family, like many of his relatives who came before him, died of tuberculosis, and although he lived to a good old age, it was only to transmit the wretchedness he himself bore so long.

I won't dwell further on heredity, as I want to come to something practical, but I repeat my assertion that it exists beyond the possibility of rational doubt, and the sooner this is admitted and taken as the basis of combined and energetic action by the medical profession and by the public, the sooner will measures be

adopted that will effectually stamp out the three great scourges I have mentioned, and probably many others. As I said before, I believe in the great benefit to be derived from modern sanitary science as promoted by Lady Aberdeen and her fellow-workers, but there is much to be done over and above what can be accomplished by such methods. They are all palliative, and can never eradicate any one of the diseases I have mentioned. It is in our power to eradicate the whole of them, and many others, if we act firmly, and if the profession act with energy, and abandon theories that are misleading to the public. It is a fact that we can confer unlimited benefits on mankind without materially interfering with the welfare or happiness of those who are afflicted with the scourges above-mentioned, and which they are sure to transmit to future generations if nothing is done to prevent it. Taking heredity as a living fact, and making it the basis on which I found my views, I say that "the marriage of the unfit" is the cause, and operation the remedy. I need not remind any medical man of what vasectomy and salpingectomy can accomplish. These operations are not only safe, but simple, in the light of modern surgery. Let some able members of the profession think over the amount of good they could do by working out this matter. Parliamentary influence should be obtained, and some time should necessarily elapse before final success, but it will surely come some time; the human race requires it, and it is not too soon to begin, in order to check the degeneration generally admitted as already too widespread. Will someone begin—my time is up.

I am, Sir, yours truly,

AN OLD M.D.

### MEDICINE AS A CAREER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your correspondent, "A Poor Practitioner," has either expressed or suggested forcibly enough the chief facts about the seamy side of professional life. The facts do not need any emphasising to those who are feeling their concrete force. The question is, can anything be done to improve the lot of the poor doctor; can anything be done to convert a calling which too often can be carried on only as a sordid trade, into a true profession, fit for cultivated, refined, and sensitive men? One thing is quite certain. The only large organisation of medical men capable of taking action—the British Medical Association—is doing, and has done nothing. I have been a member for many years, and can recall no effort by the Association to increase the political power of the profession or to promote in any way the material interests of its members. Any suggestion in this direction is mostly stigmatised as trades unionism. But trades unionism is not all vile. It is vile when it represents the narrowest, selfish motives, and disregards entirely the interests of the community and the State. These are not the motives of medical reformers, and it can be proved that improvement of the position of the rank and file of the profession would confer as much benefit upon the public as upon the practitioner. The British Medical Association includes only one half of the registered men in its membership. Is it not possible to start another society from among the 20,000 outsiders, with the objects I suggest? The medical profession has always done, and is now doing its duty nobly in the pursuit of pure science, for which it receives poor pay and no thanks, and in the promotion of every movement towards the prevention of disease; and this work would not be diminished by proper attention to their just claims upon society.

I am, Sir, yours truly,

ANOTHER POOR PRACTITIONER

Glasgow, September 17th, 1909.

### THE DECLINING BIRTH-RATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—This subject appears to be of absorbing interest to a good many of your readers. I remember reading the Presidential Address of Dr. Taylor (Birmingham) in your pages some three or four years ago. It was

the first serious pronouncement from one of our profession on a subject which is undoubtedly of national importance, and I have followed most of the correspondence which this address has from time to time produced in your columns, meanwhile eliciting the views of a good many people with whom I have been brought into contact; and the conclusion I have come to is that its national importance appears to trouble the conscience of very few. They consider it as a personal matter, to be decided as personal predilection or economic consideration may determine. For myself I do not think the deterioration or extinction of our race need be feared on the ground of a declining birth-rate; the same tendency is being exhibited in all civilised countries, and the apparent anomaly is most manifest in countries—not excluding Germany—where riches have increased. It is, therefore, not a question primarily of how many children people can afford to keep and educate, as the decrease is confined to the upper and middle ranks of the community, and the average number of births maintained only where there is most poverty and consequent physical and moral deterioration. As an example, I may mention that I have now a gardener in my service at a guinea a week; he is 27 years of age, and his wife has presented him with a baby every ten months. The four elder children are rickety, not one of them having a straight leg; the fifth is not yet on its feet. Would your correspondent, "A Student of Sociology," counsel this poor fellow to go on breeding until in process of time he brings as many of these young weaklings into the world as he has shillings in his wages? With this correspondent's views in the main I have every sympathy, and if the middle classes—the backbone of every country—thought less of their convenience and of the luxuries the curtailment of their families enable them to indulge in, I should be less disposed to fear the decadence of our race; but herein is the crux of the position—the well-to-do are failing conspicuously in their duty to the nation, whilst the poorer classes produce a continuous crop of weakly children for the taxpayer to maintain. This is the sad side of the picture that is too often lost sight of. The practical question then obtrudes itself: How would you remedy this? My answer would be by inculcating *prudence* in this as in every other phase of life to all classes alike.

I am, Sir, yours truly,  
A YORKSHIRE PRACTITIONER.

#### THE PSYCHIC TREATMENT OF INTEMPERANCE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read with the greatest interest the report published in THE MEDICAL PRESS AND CIRCULAR (September 15th) of the address delivered by Dr. J. H. Quackenbos on the psychic treatment of alcoholic intemperance.

Whilst, however, fully recognising the importance of acting on the higher human personality directly, by means of suggestion, when necessary, I would reserve hypnotic *cambriolage*—that is, the substitution of outside will for that of the patient—for exceptional cases only.

Dr. Quackenbos says that the advantage of this plan consists in "the rapidity of restoration to self-control, without the necessity for effect of will." This is, I believe, a dangerous doctrine, for permanent self-control can only result from re-education of will and character, and this is more surely effected by the frequent repetition of free auto-suggestion than by hetero-suggestion, even when the patient is consentant.

In his address Dr. Quackenbos only deals with the psychic side of treatment, but inasmuch that both forms of consciousness are conditioned by somatism, the necessity for remedying disturbances of physiological equilibrium is, even from a suggestive point of view, obvious.

Alcoholics, like other drug addicts, always suffer after the suppression of their habitual stimulant from depressions and *perversions* of different functions, and, amongst these, from heartflag, hyperchlorhydria, and general acidosis. The value of digitalis, sparteine, and of Vichy water is as great in these cases as it is in the weaning from morphia.

For the general irritability and depression which follow upon renunciation, nothing, however, can compare with the Turkish bath, which, besides having a powerful ideational effect, combines in itself, for this condition especially, the most perfect sedative and tonic action. It is, as Dr. Crothers has shown in his report to the American Association for the Study of Inebriety, a means of cleansing both soul and body, and of bringing about most expeditiously and efficiently that, for an ex-alcoholic, most desirable consummation, the *mens sana in corpore sano*. One of the great advantages, moreover, of the Turkish baths is that, by improving the neurasthenic condition, it enables an ex-addict to enjoy a bracing, tonic sea air climate, instead of being obliged, on account of post-alcoholic irritability, to resort to one more or less relaxing.

It is for this reason that I have for some years been in the habit of recommending Ramsgate, where the conditions alluded to may be associated, for this class of psychasthenic patients. The Granville, to which I send them when possible, is too well known to require any eulogy on my part, but, whilst recognising its many comforts and advantages as a quiet, ideal residential hotel, it is certain that its excellent baths would be greatly improved if the management could be brought to understand that the carpet in the sudatorium is a septic abomination, and that a tile or marble floor is a sanitary *sine quâ non*.

I am, Sir, yours truly,  
OSCAR JENNINGS, M.D.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the very interesting paper which appears in the last number of your journal, the author, Dr. John Quackenbos, although clearly describing certain classes of inebriates, and stating that vast numbers have been cured by hypnotic suggestion, has, unfortunately, left out the essential thing, namely, a full and minute account of the treatment. All I can find in his paper explanatory of hypnotism (or suggestion, as he also apparently defines the method) seems summed up in his statement that this, as he employs it, "is nothing but a straightforward, heartfelt, forceful appeal" to "the higher human personality," which when aroused is capable of dominating all that is base in man's nature. If expostulation, exhortation, and vivid description of the moral and physical ruin to which alcoholism leads were capable of weaning drunkards from their evil habit; if portrayal of the unhappiness and misery their conduct brings to those nearest and dearest to them could, unaided, bring remorse and reform, the cure of drunkenness would be in many instances a comparatively easy task. Everyone who has tried, and who has been helped by others whose moral power over the victims has been as great as can be conceived, has found that personal influence, even when founded on love and directed by high intelligence and strength of will, does not succeed in any save a very small percentage among confirmed slaves to the drink habit. If Dr. Quackenbos can explain his hypnotic system, so that it may be possible to use it in reinforcement of the moral means which we all commonly bring to bear, he will confer a boon of inestimable value upon all engaged in the treatment of intemperance.

I am, Sir, yours truly,  
MEDICAL TEMPERANCE REFORMER.

September 17th, 1909.

## SPECIAL ARTICLES.

### THE REPORT OF THE LOCAL GOVERNMENT BOARD FOR IRELAND.

THE Annual Report of the Local Government Board for Ireland for the year ended March 31st, 1909, has recently been issued. (a) It is of special interest as containing records of the work of the Board in some new fields of activity, notably in regard to old age

(a) Dublin: H.M. Stationery Office, 1909. [Cd. 4810]. Price 1s. 9d.

pensions and to the working of the recent Tuberculosis Act. Speaking of the work of the Board under the Old Age Pensions Act, the exceptional difficulties which stand in the way of the administration of the Act in Ireland are recounted. These have to do with the discovery both of the age and of the means of the claimants.

From the tables relating to poor relief we learn that there has been an increase over the previous year in the numbers of those in receipt of both indoor and outdoor relief. In the year 1907 the daily average number relieved indoors was 42,555, whereas in 1908 it increased to 43,172. As regards outdoor relief, there was an increase from 54,451 to 57,284. We are glad to note a considerable reduction in the number of lunatics, idiots, and epileptics in the workhouses. The number of trained nurses employed in the workhouses has increased by 8, to 227; this does not seem a large force for 159 institutions, with an average daily number of 14,845 patients.

The number of patients attended during the year by dispensary medical officers was 642,614, of whom 161,085 were attended at their own houses. There is a slight increase in the total of the dispensary medical officers' salaries, as well as in the fees paid for temporary services. The former sum is £101,086, the latter £14,963. Up to the present, graded scales of salaries for dispensary medical officers have been adopted in only 64 out of 159 unions.

We notice that there has been a considerable increase of typhoid fever during the year, and three considerable outbreaks occurred—one in Clontarf, one in Manorhamilton and Dromahair, and one in Kiltimagh. All of them were due to milk infection. Special reports are furnished by the inspectors of the Board dealing with these outbreaks, and of one of them, that relating to the Clontarf outbreak, we shall have something to say at another time.

On the subject of tuberculosis the Board quotes with approval a series of thoroughgoing resolutions carried at the International Congress at Washington, and then makes the astonishing statement that "these resolutions endorse the general outline of policy set forth in our Report for the year 1906-7, and to a large extent embodied in the Tuberculosis Prevention (Ireland) Act, 1908." Those who remember the persistent inertia of the Local Government Board until stirred into activity by the energies of Lady Aberdeen, and who reflect on the inefficiency of the boasted legislation, will be somewhat staggered.

Dealing with the Dairies, Cowsheds, and Milkshops Order, the Board remarks:—"We have strongly recommended District Councils, where the dairying industry is extensively carried on, to appoint veterinary surgeons as chief inspectors to supervise the work of the ordinary inspectors."

The regulations which the inspector has to carry out are framed for the inspection of cattle in dairies, and for prescribing and regulating the lighting, ventilation, cleansing, drainage, and water supply of dairies and cowsheds in the occupation of persons following the trade of cowkeepers or dairymen; for securing the cleanliness of milk stores, of milk shops, and of milk vessels used for containing milk for sale by such persons; for prescribing precautions to be taken for protecting milk against infection or contamination.

We find a difficulty in understanding why the Board should have exerted its influence to have veterinary surgeons rather than medical men appointed to these positions.

Special reports from the inspectors on various subjects contain many matters of interest, but our space is limited. Speaking of enteric fever in Galway, Sir Acheson MacCullagh says:—"Thirty-four cases of enteric fever were reported in this urban district during the year; 12 of these occurred in the No. 1 and 22 in the No. 2 district. The cases were notified at different periods, and from various localities throughout the town, and no common source could be assigned as to their probable cause. The milk supplies were very varied, and the analysis of the town water supply was most favourable."

This statement is hardly as frank as it might be. The facts are that last year a consumer in Galway submitted the water to bacteriological examination, and

the report, subsequently made public, showed that the water contained large numbers of *B. coli*. On this report being forwarded to the Urban Council, the Council, after some delay, ordered a further examination to be made. The report stated that but few *B. coli* were to be found. The Council ordered also a chemical analysis, but they have never published the result. Sir Acheson MacCullagh can hardly have been ignorant of these facts, and therefore we cannot help wondering if he thinks the presence of *B. coli* a "favourable" point in the analysis of a drinking water.

The report of Surgeon-Colonel Flinn on the outbreak of enteric fever at Clontarf contains so many points of importance that we are compelled to leave it over to be dealt with in a special article.

## MILITARY & NAVAL MEDICAL NOTES.

### FIELD AMBULANCE TRAINING FOR MEDICAL OFFICERS.

—An experiment with the Cavalry Field Ambulance was made at the tactical operations in the Southern Command. Two forces were supposed to have suffered casualties, one to the extent of 20 killed and 75 wounded, and the other to 10 killed and 45 wounded. The ambulance was reported by the military correspondent of the *Naval and Military Record* to have quietly dealt with the supposed victims, dead and wounded, and dealing with their sham wounds with the greatest dexterity. It was just the training the medical personnel required, and their work all-round was voted a success.

**NAVAL MEN'S TEETH, SIGHT, AND HEARING.**—The Admiralty having had under consideration the large invaliding out of the Service on account of defective teeth which occurs at the periodical "Boards of Survey" (as they are called in the Navy, while "Medical Boards" in the Army), it has published the following rules to be observed:—(1) No man is to be invalidated for defective or deficient teeth unless the consequences have already rendered him unfit to perform his duty, and in all such cases the resultant disease is to be specified in the Survey report. (2) No man with defective or deficient teeth who is on draft for foreign service is to be invalidated out of the Service merely because he is rejected for draft on account of the state of his teeth. An order has also been issued directing that eyesight and hearing are to be periodically tested with a view to obtaining information which will assist commanding officers in stationing the crew for action. In future, also, the medical examination of men for draft is to include eyesight and hearing tests.

**IDENTITY TICKETS IN WAR.**—At the Medical Congress, Budapest, a paper on the unification of cards of identity for the wounded in the field has been presented by Lieut.-Col. W. G. Macpherson, R.A.M.C., and it is expected this compassionate aim will be achieved. There is also an effort to bring about uniformity in the necessities and requirements for "first aid" in all armies.

It has been decided to discontinue the issue of woollen belts (more commonly known as "cholera" belts) to troops going to foreign stations, or moving from one colonial station to another.

A FORTNIGHT'S course of instruction for lieutenants on probation, R.A.M.C., at the Army Service Corps Training Establishment, Aldershot, is in future to be held in May, June, November, and December.

It has been sanctioned that an officer of the Indian Medical Service shall be appointed Professor of Biology at the Calcutta Medical College.

MAJOR B. G. SETON, Indian Medical Service, Secretary to the Director-General of the Service, has taken over the honorary Secretaryship of the Pasteur Institute at Kasauli.

## SUMMARY OF RECENT MEDICAL LITERATURE, ENGLISH AND FOREIGN.

*Specially compiled for THE MEDICAL PRESS AND CIRCULAR.*

**Sarcoma of the Ovaries.**—Lockhart (*Journ. Obst. and Gyn. Brit. Emp.*, XVI., 2). Cohn found malignant disease of the ovary in 16.6 per cent. of 600 cases of ovariectomy performed by Schröder. Leopold found a similar condition in 26 out of 116 laparotomies for ovarian tumours. Of all the malignant tumours of the ovary, sarcomata are those which are least frequently met with. The author has operated upon 65 cases for ovarian tumour. Of these, 14 were malignant, 7 were sarcomata, and 1 mixed sarcoma and carcinoma. Five of the tumours were primary and 2 were secondary, both ovaries being affected in one instance. It apparently affects multiparæ and nulliparæ equally, and may be met at any age. The very young are especially susceptible. The first period of exceptional liability ends at puberty, and the second extends from 25-45 years. Pain may be an early symptom, and this induced 5 of the author's cases to seek advice. Even after complete removal of the seat of disease one is not safe, as only 25-50 per cent. of the patients remain free from recurrence. From present knowledge all ovarian tumours ought to be removed as soon as discovered, and great care should be exercised not to allow the escape of any of their contents during operation. F.

**Fibromyomata Uteri.**—McDonald (*Journ. Obst. and Gyn. Brit. Emp.*, XVI., 2) reports 700 cases studied statistically and pathologically. The routine microscopical examination is not only of importance in regard of the tumours, but also the adjacent tissues removed at operation should be carefully examined. This has not been the case in many series reported, and therefore no other series is combined with this one of 700 cases. Analysis of the cases shows that the greatest number of cases came to operation between 40 and 50 years of age; less between 30 and 40; less than 3 per cent. of the cases were under 30. The tumours were single in about one-third of the cases. The largest tumour weighed 20 lb., removed from a woman weighing 65 lb. when the tumour was removed. Analysis of the degenerations showed hyaline degeneration in 18 per cent., and with the increase in the age of the patient was more frequent between 40 and 60 years of age. In 9 per cent. calcareous degeneration occurred, and was present in very few cases below 40 years of age; it was found most frequently between 40 and 50 years, with slightly decreasing frequency as the patient became older; it occurred 6 times out of 20 cases in which fibroids and adeno-carcinoma were associated. Cystic degeneration was found in 3 per cent., and seems to have some connection with sarcoma, 2 of the sarcomatous cases being cystic. Necrosis and inflammation were noted in all stages. Necrosis occurred mainly in large tumours, in which from the size or other causes the circulation was disturbed, and was found in 8 per cent., with increasing frequency as age advanced, being present in 20 per cent. over 60 years, 9 per cent. from 50 to 60, and less often in the three preceding decades. Adeno-carcinoma was found in 2.9 per cent., but in no case below 40 years of age, and increasing in frequency with the age of patients. Squamous cancer in .8 per cent. also showed the same relation to age—1 case below 40, 3 per cent. from 50-60, and 4.6 per cent. from 60-70. The proportion of these two forms of cancer is the reverse of the usual, as shown by Piquand. The relatively higher frequency of adeno-carcinoma with fibroids may be due to a common ætiological factor which may be in the uterus itself. There were 7 cases of sarcomatous degeneration in the 700 tumours. During the time the 7 cases were observed, there were 12 other cases of sarcoma of the uterus. The small percentage in this series may be due to the fact that no tumour was included unless it was distinctly shown to be a true sarcomatous degeneration. This form of

degeneration was almost constantly associated with necrosis or hæmorrhage. Chorion epithelioma was found in 2 cases, both after abortion; 1 infiltrated the substance of the fibroid tumour. The total malignant complications were 5 per cent., the adeno-carcinoma and sarcoma (nearly 4 per cent.) being due to or influenced by the presence of fibroids; there was only 1 below 40 years of age, and with each decade after 40 the percentage increased, being 5 in the fifth, 12.7 in the sixth, and 23.8 in the seventh. The tubes showed salpingitis or perisalpingitis in 27.5 per cent.; in most cases the diagnosis was made microscopically. The association of salpingitis with fibroids is probably often overlooked because of lack of macroscopic change. Appendicitis was found in 21 per cent., and the same applies to it as to the tubes; the effect of fibroids on both the tubes and appendix is largely mechanical. In this series fibroid tumours were found in 26 women at autopsy, and heart lesions were found in 11.5 per cent. of these. The changes were secondary to anæmia from hæmorrhage, or to malnutrition. In a series of 2,600 pregnancies, 13 cases of pregnancy and fibroids were studied. In 5 cases the placenta showed areas of necrosis, in 2 cases involving the whole thickness of the placenta. In several cases there were placental infarcts, and 1 showed moderate calcareous degeneration. In the series of 700 cases of fibroids, pregnancy was associated in 16 cases. In 1 it was apparently the cause of marked increase in growth, followed by necrosis; in 3 cases there was moderate increase of growth and necrosis. From these statistics the following conclusions are drawn: that fibroid tumours are liable in a large percentage of cases to dangerous changes and complications; that these dangers almost all increase in proportion to the age of the patient, particularly in the case of malignancy and necrosis—in the case of malignancy 5 per cent. from 40 to 50, 12.5 from 50 to 60, and 25 from 60 to 70. Necrosis occurs in 8 per cent. of all cases, and in 33 per cent. of cases at or above 60 years of age. It is obvious that the menopause does not bring a cure to patients with fibroids, but exposes them to more grave dangers. Were there distinctive symptoms by which the advent of malignant or necrotic change could be recognised, the dangers of expectant treatment would be diminished, but there are none, and after their advent they advance rapidly and greatly increase the dangers of operation. The expectant treatment offers nothing towards the cure of fibroids, but hopes that the menopause, though often delayed, will remove some of the symptoms. F.

**Ruptured Tubal Pregnancy Twice in the Same Tube, with a Normal Pregnancy Intervening.**—Pearson (*Journ. Obst. and Gyn. Brit. Emp.*, XVI., 2) records an interesting case, with the following summary of her history:—Jan., 1903, married; Nov., 1903, ruptured tubal pregnancy (left), loop of tube excised; Nov., 1905, normal full-time pregnancy; — 1907, ruptured tubal pregnancy (left), remains of tube excised; May, 1908, normal full-time pregnancy; Feb., 1909, four months pregnant. F.

**The Operative Treatment of Pelvic Infection.**—Mallett (*Amer. Journ. of Obst.*, LX., 2).—In discussing the operative treatment of pelvic infection, prophylaxis and palliative measures are not considered. Should the case be one of gonorrhœal endometritis, efforts should be directed to limiting the disease to that tissue. Should the tubes be involved, and resolution not occur, the case becomes an operative one. The best way to treat this condition is by vaginal section and drainage, for this can be done with safety during the acute stage, and the necessity for waiting until the tubes and ovaries are distended with pus and damaged beyond

repair can be avoided. As soon as any induration is felt in the floor of the pelvis, or the tubes and ovaries are found to be enlarged and tender, a vaginal section should be made regardless of the temperature. The tubes are examined, and the os abdominalis opened and drained. Inflammatory exudates are separated and entered with the finger, whether they be in the cellular tissue or in the pelvic cavity. When there is pus in the pelvis the vaginal route should be chosen, as it gives better drainage, less shock, and is safer, and is followed by less danger of intestinal adhesions. If it is desired to enucleate the diseased ovary and tube, the abdomen may be opened at the same sitting with less danger. When pus is diagnosed in the pelvis, no time should be lost in evacuating it, whether acute or chronic, provided the vaginal route is adopted and the abscess drained through the *cul-de-sac*. Care must be exercised in the after-treatment of these cases, because of the tendency of the opening in the tube to close and stop drainage; by attention to this detail many tubes can be saved from further disorganisation and restored to usefulness. F.

**The Prevention of Perineal Lacerations.**—Macomber (*Amer. Journ. of Obst.*, LX., 2).—After the cervix uteri is dilated to the size of a dollar or a little larger, and labour pains are active, the dilating bag of Champetier de Ribes, or a modification, is boiled, and introduced into the vagina. A bulb syringe is connected with the tube, and while the bag is held in place, a warm antiseptic or sterile solution is slowly forced into it. The tube is then secured by clamp, and the bag left to be expelled. The bag must be filled slowly, as the rapid dilatation causes pain and may do harm. Filling the bag should take 15 or 20 minutes. With the bag in place, the pains, while dilating the cervix, are also crowding down the bag and dilating the soft parts; thus the second stage is shortened, the cervix, being pressed between the head and the bag, dilates more rapidly. Many instrumental deliveries can be avoided, and labour terminated in a reasonable length of time and without laceration, by using the bag. The direction of the force is always towards the outlet, and not towards the centre of the perineum. As the bag is about to be expelled it should be constantly held so as to get the full benefit of its largest diameter. When the presenting part is much larger than the bag, a little chloroform should be given as it passes over the perineum, and the head should be held back and worked out between the pains. The author's record with the bag is 3 lacerations out of 85 primiparæ, 12 of which were instrumental. F.

**Induction of Labour at Term as a Matter of Routine.**—Wright (*Amer. Journ. of Obst.*, LX., 2), during the last three years, has followed the rule to induce labour within three days after the patient has reached term as a matter of routine in all cases. With regard to the diagnosis of term, the author considers that if the cervix is found to have been taken up, labour may be induced, and that it is better to be one or two weeks premature than to run the risk of being four or five weeks late. The method of induction is, to pack the vagina tightly with the patient in Sims' position; at the end of 24 hours remove packing and re-pack; if labour has not started, remove the second packing, introduce one or two bougies, 11 or 12 English size, and then re-pack. In most of the cases the use of the bougie is not necessary, and when it is used it is practically always sufficient. F.

**A Method of Obtaining Walcher's Position.**—Frankenthal (*Amer. Journ. of Obst.*, LX., 2).—Described at the Chicago Gynecological Society. The patient is placed on her side, the side which contains the part that is to rotate to the front, and then the harness is attached. The pelvic bandage, a wide sheet, reaching from the dorsal vertebrae to the end of the sacrum, is placed round the woman and attached to the side of the bed, so as to draw the abdomen over to the edge of the bed. Then a four-tailed bandage is placed across the chest, so that one end goes each side of the neck and one end round the side under each arm; this is attached to the other side of the bed, so as to draw the body across, so that the shoulders and

ilium are on the same line. Next a bandage is placed around and above the ankles, and attached to the side of the bed, where the chest bandage is fastened and drawn tight, so that the thighs are drawn up and backwards towards the shoulders at an obtuse angle; this angle can be increased after the patient has been in position for a little time by pushing the knees backwards, and if the liquor amnii has escaped in the meantime. The position is not painful, and the patient does not require constant attention as when in Walcher's position. The method is illustrated by photographs. F.

**A New Method of Inducing Local Anæsthesia.**—Ransohoff (*Lancet-Clinic*, August 7th, 1909) reports the following case:—Patient, æt. 72, had been suffering for three years from a chronic osteo-myelitis of the hand, which became so painful as to necessitate an amputation. An Esmarch bandage was applied below the insertion of the deltoid. Under infiltration anæsthesia the brachial artery was exposed, and the needle of a hypodermic syringe inserted into its lumen, and 1 cc of a 2 per cent. cocaine solution injected into the artery in the direction of the blood current. After the lapse of two minutes the anæsthesia was absolute, and an antibrachial amputation was done entirely without the knowledge of the patient. S.

**A Simple Operation for Prolapse of the Rectum in Children.**—Ekehorn (from *Med. Review*, August, 1909) describes an operation which consists in fixing the posterior rectal wall to the sacrum by a transverse suture, no incision of the skin or rectum being required. The prolapsed rectum is first replaced and held in the required position by the forefinger of the left hand. A moderate sized needle on a handle is now passed through the skin to one side of the extremity of the sacrum, and is carried through the soft tissues till it pierces the rectum and meets the finger, which guides it to the anal orifice. The needle is now threaded with stout silk, one end of which is drawn back with the needle. By a similar procedure the other end of the ligature is brought out at the same level on the other side of the sacrum. The two ends of the ligature are tied together over the skin. No dressings are required, and the patient need not be kept in bed. After a fortnight the suture is removed. No rise of temperature followed this operation in the writer's experience of four cases, and no inconvenience was caused by the presence of the suture after the pain of the operation had passed off. S.

**The Double-Filigree Operation for the Radical Cure of Inguinal Hernia.**—McGavin (*Brit. Med. Journ.*, August 14th, 1909) reports thirty-three cases in which he had used his methods of operation. He states that he has carefully excluded from his series of cases any in which there was even a remote prospect of cure by Bassini's method; consequently, he has reported no case which was not considered by others as well as by himself to be quite outside the scope of any operative method hitherto published. Twenty of the patients have been operated on from 1½ to 4½ years ago, and have been constantly engaged in heavy work since the operation, without using any truss. The largest inguino-scrotal hernia was in a seaman, æt. 62. It was 15 in. in length and 25 in. in circumference. The writer's method consists in strengthening the wall of the inguinal canal by the implantation of two filigrees of silver wire in the tissues in such a way that subsequent stretching or bulging is rendered impossible, and the necessity of a truss is entirely done away with. The filigree is made in two sections, a pubic and an iliac. The former is always made of the following dimensions: At the narrow end its width is ¾ in., at its widest end 1½ in. Its length is 1½ in., this being the usual length of the adult inguinal canal. The iliac section varies in size to meet requirements, but is usually 2½ to 3 in. long. The operation is at first conducted exactly as in Bassini's operation, except that the aponeurosis should be split to a point further out, and the peritoneum more freely separated from the posterior surface of the conjoined tendon

The pubic section of the filigree is placed upon the peritoneum, its narrow end being close to the pubic spine, and its wide end at the inner margin of the internal abdominal ring. The iliac section is placed beneath the aponeurosis in such a way that its inner end lies over the internal abdominal ring and upon the cord for a space of  $\frac{3}{4}$  in., and the outer end carried outwards and laid upon the surface of the internal oblique. Finally, the aponeurosis is sutured in place, and the wound closed. The author considers that the only disadvantage of the operation is that, if suppuration should occur, the iliac section, and possibly the pubic section, may shift their positions, or, if only a slight sinus should develop, that convalescence may be unduly prolonged. If suppuration occurs, and the filigree shift, the probability is, that cure will fail, just as it does in cases where no filigree is used. S.

## MEDICAL NEWS IN BRIEF.

### Sheffield Exhumation—Attendance and Signature on Certificate by Unqualified Assistant.

At Norton Cemetery, on September 7th, the body of Mrs. Alice Nicholson, wife of a carpenter, who died on August 2nd in Ecclesall Union Hospital, was exhumed by order from the Home Office.

The Coroner said that the husband reported to him that about June 26th this year he engaged Dr. Jones, of Wostenholm Road, to attend to his wife, who was expecting to be confined some time in August. The doctor visited her about 16 times previous to her confinement, and supplied her with medicine. He promised to attend her himself, if possible, at her confinement. When his wife was taken ill on Saturday, July 24th, the husband sent for Dr. Jones, but he was unable to attend, and sent his assistant, Mr. William Perry. The assistant arrived about 12.30 p.m., and attended the case. Twins were born. The assistant visited her again on Sunday, July 25th, about noon, and again on Tuesday, July 27th, just before noon. On the following day—Wednesday, July 28th—Dr. Jones himself visited the case in the evening, about 6.30. The husband did not see him, but was told that the doctor had remained with his wife about an hour. He ordered her removal to the Ecclesall Union Hospital, and she was taken away in the ambulance about 7.45 that night. On Thursday the husband received a message from the Union, telling him that his wife was seriously ill. He saw her at 11.30 a.m., and she told him that she was very comfortable and had been kindly treated. He spoke to the doctor in charge, who told him that she was suffering from puerperal fever, and was hopelessly ill. The husband visited her several times until her death on Monday, August 2nd.

Dr. Garrick Wilson said he had made a post-mortem examination. Five other medical men were present—Drs. Waldron, Jones, Graham, Simpson, Phillips and Williams. The body appeared to have been buried about a month. There were no outward marks of violence. The organs generally were healthy, and in a state consistent with death from blood poisoning. He could not definitely swear as to the cause of death.

Dr. Walrond, M.R.C.S., who acted as *locum tenens* at Ecclesall Union Workhouse during July, explained the history of the case after admission to the institution.

Answering a juryman's question, witness said:—My opinion is, as an independent individual, attending the case, that what I find might have occurred in any case, even if a specialist had been with the patient at the time of confinement. My opinion honestly is that it was due to neglect.

Dr. David Jones, surgeon, stated that his dispenser and surgery attendant had been with him 2½ years. He knew the dispenser was not a qualified medical man, but he had instructions to attend patients in case of emergency, if none of the partners in the firm were available. There were four qualified men in the firm. The dispenser was quite competent to act in that way. He had instructions always to report immediately to one of the partners. He had attended close on 300 cases of child-birth without a single mishap. Witness promised the husband that he would attend deceased

personally if possible. He was not away when the deceased became ill, but he had two urgent cases in hand. On reaching his surgery he found that the dispenser (Mr. Perry) had gone to deal with the case. The dispenser reported in the usual way. There was nothing unusual about the case. Next day witness had a very busy morning, with a serious operation, attended by all three partners, so he directed his dispenser to see Mrs. Nicholson. He reported that the case was going on satisfactorily, and that she could be safely left until Tuesday. Witness intended seeing her that evening, but had other urgent cases which kept him till 11 p.m.

The case was not visited the following day, and on Tuesday it would have been dangerous for him to visit deceased owing to another case he had attended. The dispenser again saw Mrs. Nicholson. On the Wednesday a message came to him at 3 o'clock asking him to attend personally. He promised to go in a couple of hours. As soon as he had got a specialist's opinion that it was safe for him to see Mrs. Nicholson, he went to the house. She had a high temperature, and suspicious symptoms of blood poisoning. He made a close examination of the patient, and strongly advised her removal to the Ecclesall Union Hospital. He secured her removal within an hour. This was on July 28th. The dispenser saw her on the previous day. In his (witness's) opinion, none of these suspicious symptoms were visible when last the dispenser saw her on July 27th. He believed that the same sequence of events would have developed if any qualified man had been in attendance.

The husband then called attention to the fact that when the certificate from the Medical Officer's department was filled in, Mr. Perry signed Dr. Jones's name instead of his own. Was that right? He did not see why, when he paid for a doctor, a man who was not qualified for the job should be sent. That sort of thing would not be tolerated in his trade. When he was paid for a job, he was expected to do it.

Dr. Jones, replying to the first part of the question, said it was not necessary for the doctor to fill in the form. The midwife or the father himself could do it.

A Juryman: But who signed your name?

The Doctor: I authorised that because it is purely a formal matter.

The Coroner: What do you say to this, doctor? The certificate is filled in by Mr. Perry, in the place where you ought to have signed it, as "D. T. Jones." Is that correct?

Dr. Jones: Yes. Mr. Perry delivered her, but on the Sunday I intended attending her myself.

The Coroner: But you did not attend her until she was a dying woman, and yet you are certified here to the authorities as having attended her, and you did not do anything of the kind. They may pass it and welcome if they like, but it is an improper way of filling in these certificates, because it is not true. (Hear, hear.) It cannot, therefore, be correct.

Dr. Jones: But it is so signed on Sunday, and I was going to see her that night.

A Juryman: But you did not attend her at her actual confinement.

Dr. Jones: No, but they only ask who is attending. It was filled up with my authority.

The Coroner: That makes it worse still.

The husband said Mr. Perry filled in Dr. Jones's name after he himself had signed the form.

Mr. Perry was understood to deny this.

The Foreman asked Dr. Ralph Williams, from the Medical Officer's department, if that sort of thing was accepted by the Medical Officer of Health.

Dr. Williams: We should not demand the personal signature of the doctor, but we should draw the conclusion that the doctor was attending the case, and not a midwife.

The Coroner: It is wrongly and improperly filled in—(hear, hear)—for the simple reason that it is a lie on the face of it. That cannot be right under any circumstances, and it would decidedly mislead the authorities to whom it is sent. But you need not deal with that any further than by adding that the woman died from puerperal septicaemia. If you think there was any irregularity, it is your duty to add it to your verdict for two reasons—hoping it may lead to a better

state of things in the future, and stop any irregularity that has occurred up to now, and to show people that they may not do this sort of thing with impunity. If a person has been attended by an unqualified man, she is in the position of not having been attended at all, so far as the law is concerned.

The jury retired to consider their verdict, and found that deceased died from natural causes, and added that they thought she should have been attended by a fully qualified doctor from the first.

#### Home Treatment of Tuberculosis in Dublin.

THE quarterly meeting of the Hospitals Tuberculosis Committee was held in 76 Grafton Street, Dublin, on Thursday, the 9th inst. Present:—

Her Excellency the Countess of Aberdeen, accompanied by Lady Pentland; Sir Arthur Chance (in the chair); Dr. M. F. Cox; Dr. Alfred Parsons; Dr. G. Peacocke; Dr. T. Percy Kirkpatrick; Dr. J. Lumsden, and Sir William J. Thompson, hon. secretary.

The report of Dr. Daniel, who had been placed by the Women's National Health Association at the disposal of the Committee to attend cases that were receiving no medical aid, was considered most satisfactory. It was felt that in this way a great want was being met.

The work done during the last six months by the two Tuberculosis Jubilee nurses working in Dublin was next reported. 247 patients have been attended—of these 125 were old cases, and 122 new cases.

In all, 3,504 visits were paid to the patients' homes. It is a significant fact that almost two-thirds of the patients themselves seek the nurses' aid. This is not to be wondered at when it is realised what is done for their patients through the Samaritan Committee, in addition to the actual nursing, help and advice which enables patients to carry out doctors' orders in their own homes. 63 families received nourishment; 30 received clothes, shoes, bedding, etc.; 10 families' rents were paid while the breadwinner was under special treatment; 87 children of parents suffering from tuberculosis were sent to the country through the Fresh Air Fund; 3 families of children were boarded out while the mothers were in hospital; 60 rooms were disinfected; 5 families were removed to more healthy homes; for 7 patients work had been obtained, and 16 patients had been admitted to Newcastle.

There were 66 families each occupying one room, and in 35 families more than one member was affected. The total earnings of the families attended when the breadwinner is ill is estimated not to exceed 5s. a week on an average.

Mrs. M. A. Sullivan, the Convener of the Samaritan Committee, reported "that £130 had been spent on tuberculosis cases since February, 1908, and that does not include subscriptions collected for some patients for Newcastle. Then a large quantity of clothing was given to patients; beds or beddings were equipped, and in addition all the charitable societies were generous in their help." Mrs. Sullivan will gladly receive any help for this good cause.

The nurse employed by the Terenure Branch of the Women's National Health Association reports that for four months she attended 22 consumption patients, and paid 214 visits. She also has been the means of giving a great deal of assistance to patients in the way of beds, clothes, nourishment, and in addition to the ordinary nursing.

The three nurses and the doctor remark that patients or their friends ask that their homes be disinfected. This fact together with that mentioned before, that two-thirds of the patients request the nurses' services, show that the people amongst whom the nurses work are commencing to understand something about the nature of the disease, and are themselves assisting in trying to stamp it out.

#### The Society for the Study of Inebriety.

THE next meeting of this Society will be held in the Rooms of the Medical Society of London, on Tuesday, October 12th, 1909, at 4 p.m. (afternoon meeting), when Dr. J. Milne Bramwell will open a discussion on "Suggestion and Its Role in the Treatment of Inebriety." Each member and associate is at liberty to introduce a visitor. We understand that the Council

have established a reserve fund to provide means for the furtherance of the work of the Society. Contributions are earnestly invited in order to assist in meeting the expenses of the Society, and in helping the conduct of scientific investigations and educational work relating to the study of alcohol and alcoholism. All contributions should be forwarded to the Hon. Treasurer, G. Basil Price, M.D., 53 Devonshire Street, Portland Place, London, W.

#### Royal College of Surgeons of England—Admission of Women.

THE Home Secretary has signified to the Council of the Royal College of Surgeons his decision to approve the by-laws regarding the admission of women to the examinations for the diplomas of the College. He has further expressed his willingness to sign the formal document which is to be submitted after the next meeting of the Council of the College on October 14th.

#### The Hospitals Bill in Parliament.

THE following is the text of the Hospitals Bill, introduced in the House of Commons by Mr. J. MacVeagh. It proposes to empower local authorities to strike a rate in aid of local hospitals:—

1. From and after the passing of this Act it shall be lawful for any district council, corporation, board of town commissioners, county council, or other rating authority to strike a rate not exceeding threepence in the pound on the valuation towards the erection or maintenance of any hospitals situated within the area of charge.

2. The allocation of any rates so levied shall be subject in England and Wales to the approval of the Local Government Board, in Ireland to the approval of the Local Government Board for Ireland, and in Scotland to the approval of the Local Government Board for Scotland.

3. This Act may be cited as the Hospitals Act, 1909.

#### Infection and "Rats."

In the House of Commons, on Friday last, Mr. A. King asked the Under-Secretary of State for India whether the Indian Government still adhered to the theory that plague in man is due to bites of infected rat-fleas; and, if they do not, what theory are they now acting on, and had they made such changes in their administration as are necessary to meet the new situation.

The Master of Elibank replied that the connection between bubonic plague in man and plague in rats was well established, and rat destruction continued to hold a prominent place among the preventive measures adopted by the Government of India. The Government of India was now considering an important scheme for the improvement of the sanitary service.

#### Death of a Consumptive under Christian Science.

SOME remarkable evidence (reported in the *Standard*) was forthcoming at an inquest held at Worthing, on September 13th, touching the death of Mrs. Lilian Elizabeth Harper, the widow of an electrical engineer, who died suddenly on Saturday from hæmorrhage of the lungs. Mrs. Harper, who was 39 years of age, had been suffering from consumption for the past five years, and until last Easter had been taking medicine prescribed by a London physician. On the advice of a sister she then consulted a local Christian Scientist, with whom arrangements were made for a course of Christian Science treatment.

This treatment, the Christian Scientist informed the coroner, consisted of prayers twice daily, for which a sum of 5s. a week was paid by the sister. The regular fee for Christian Science treatment, the witness added, was a guinea a week, but a great deal of work was not charged for. Asked if he gave the deceased to understand that her condition was curable by Christian Science, the witness replied, "All things are possible with God." Replying to another question by the foreman, the witness said that cases of fractured limbs would be taken to a surgeon.

In returning a verdict of death from natural causes, the jury expressed the opinion that the practice of Christian Science, especially in cases of serious disease, was harmful, and greatly to be deprecated, and, further, that the taking money for treatment was un-Christian.

## NOTICES TO CORRESPONDENTS, &c.

**NOTE.** CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

### SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs 15.12. Messrs. Dawson and Sons are our special agents for Canada.

### ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, 25; Half Page, 23 10s.; Quarter Page, 21 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at 23 10s.; 26 at 23 5s.; 52 insertions at 23, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

MR. WINTON S.—The individual about whom you are making inquiries, although he gives it out that he has English qualifications, is not on *The Medical Register*, and we have reason to believe that those he possesses are of American origin. We know nothing of him personally, but the proceedings you describe are not creditable to the member of an honourable profession.

DR. JAMES H. (Chelsea).—The queries in your note to hand will be answered in our next, or by private letter, your communication having arrived too late for reply in our present issue.

### HOUSING AND TOWN PLANNING BILL.

THE Clause dealing with county medical officers runs:—"By Clause 68 (2) it is enacted that the Local Government Board is to prescribe the duties of county medical officers of health, although they are appointed by county councils and paid exclusively from county funds. Here again we submit that it is inconsistent with local self-government for the locality to appoint and pay, and for a Government department to prescribe the duties of the officers and vary them as it chooses. The best method would be to set out in the statute the duties of county councils with regard to public health and direct them to appoint a medical officer to assist in carrying them out."

MR. WHEELER (Liverpool).—The advertiser is one of the worst of quacks. Take no notice of his specious arguments and pretences and hold no further correspondence with him, or you will suffer in body as well as pocket as all his victims have done.

ONE INTERESTED.—The decrease of births is steady throughout the whole of England, but not nearly so great in Ireland and Scotland. But the death rate is also much below the average, consequently, although the population is not increasing at the same rates as formerly, it is always well above the loss occasioned by a diminished birth rate, emigration and other causes. You will find full details in the weekly returns by the Registrar-General.

### GERM-FREE MILK.

A CORRESPONDENT sends us the following:—"Are you sure this milk is free from germs?" inquired the cautious young housekeeper. "Yes, lady," replied the milkman, unguardedly; "we boil every drop of water that goes into it."

MR. J. N. N. (Glasgow).—The usual application for information was sent, but as no reply was received, it was considered that no reference was necessary.

SENIOR STUDENT.—You cannot do better, the book is an admitted success and deserves the encomiums pronounced.

ERRATUM.—In the letter in our last issue signed by Clement H. Sers, the expression, "urban industries can only provide a limited number with both," should read with *work*.

## Vacancies.

Great Northern Central Hospital, Holloway, N.—Resident Medical Officer. Salary £120 per annum, with board, lodging, and washing. Also Senior House Surgeon, Senior House Physician, Junior House Physician, and two Junior House Surgeons, all for six months. Salary of Senior Officers at rate of £45 per annum, and of Junior Officers at rate of

£35 per annum, with board, lodging, and laundry. Also Anaesthetist. Salary 10 guineas per annum. Applications to the Secretary.

Fermanagh County Hospital, Enniskillen.—House Surgeon (Anaesthetics). Salary £72 per annum. Applications to C. Wilson, Secretary. (See advt.)

Gorey Union.—Medical Officer for the Camolin Dispensary District. Salary £120 per annum, with Registration and Vaccination Fees, etc. Immediate application to R. Creighton, Clerk of Union. (See advt.)

Macclesfield General Infirmary.—Senior House Surgeon. Salary £100 per annum, with board and residence. Also Junior House Surgeon. Salary £60 per annum, with board and residence. Applications to the Chairman of the House Committee.

Royal London Ophthalmic Hospital, City Road.—Senior House Surgeon. Salary £100 a year, with board and residence in the Hospital. Applications to the Secretary not later than the 30th inst.

Wolverhampton and Staffordshire General Hospital.—Resident Surgical Officer. Salary £125 per annum, with board, lodging and laundry. Immediate applications to J. Stephen Neil, House Governor and Secretary, Wolverhampton.

North Staffordshire Infirmary and Eye Hospital, Hartshill.—Medical Secretary and House Governor, age not under thirty-five. Salary £500 per annum, non-resident. For further information apply to the Acting-Secretary.

Nottingham General Dispensary.—Two Assistant Resident Surgeons. Salary £160 each, with apartments, attendance, light, and fuel. Applications to C. Cheesman, Secretary, 12 Low Pavement, Nottingham.

County Asylum, Rainhill, near Liverpool.—Assistant Medical Officer. Salary £150 per annum, rising to £250, with furnished apartments, board, attendance, and washing. Applications to the Medical Superintendent.

Derbyshire Education Committee.—Assistant School Medical Officer under the County Medical Officer of Health. Salary £250 per annum, rising to £350, with £100 a year to cover travelling and other incidental expenses. Further particulars of Dr. Sidney Barwise, County Medical Officer of Health, Derby.

Stirling District Asylum.—Assistant Medical Officer. Salary £125 per annum, with board, etc. Apply, stating age, with testimonials, to the Medical Superintendent.

Royal Surrey County Hospital, Guildford.—House Surgeon. Salary £100 per annum, with board, residence, and laundry. Applications to the Hon. Secretary.

Plaistow Hospital for Infectious Diseases, London, E.—Junior Assistant Medical Officer. Salary £100 per annum, with all found. Applications to Dr. Biernacki, Medical Superintendent, Plaistow Hospital, London, E.

Bolton Infirmary and Dispensary.—Junior House Surgeon. Salary £100 per annum, with apartments, board, and attendance. Applications to W. W. Cannon, Esq., 20, Mawdsley Street, Bolton.

West Norfolk and Lynn Hospital.—House Surgeon. Salary £100 per annum, with board, lodging, and washing. Applications to H. R. Kenny, Secretary.

## Appointments.

CAMERON, M., M.B., C.M.Glasg., Medical Officer and Public Vaccinator to the Cere Parish Council, Fife.

HEATHCOTE, HENRY CHARLES, M.B., Ch.B.Vict., Medical Officer for the Newton District, Somerset.

PRATT, CHARLES CLARIDGE, L.S.A.Lond., Medical Officer for the Mordard Bishop District, Crediton (Devon).

PITTERCH, J. R., M.B., Ch.B.Edin., Certifying Surgeon under the Factory and Workshop Act for the Llangefni District of the county of Anglesey.

RISLEY, S., M.D., C.M.Edin., Honorary Ophthalmic Surgeon to the Sheffield Institution for the Blind.

SPIDSON, C. A., M.D., B.S.Lond., M.R.C.S., L.R.O.P.Lond., Honorary Assistant Surgeon to the Wolverhampton and Staffordshire General Hospital.

## Births.

CRABTREE.—On Sept. 12th, at Pelham, Hertfordshire, the wife of E. F. Crabtree, M.R.C.S., L.R.C.P., of a son.

TULK-HART.—On Sept. 20th, at 4 Gloucester Place, Brighton, the wife of T. Tulk-Hart, M.D., of a son.

## Marriages.

TOURS.—DAVIES.—On Sept. 15th, at St. Helen's Church, North Kensington, Henry John, second son of the late Berthold Tours, to Louisa Canning, only daughter of the late Gomer Davies, M.D.

## Deaths.

DAY.—On Sept. 14th, at Holly Hill, Emma, widow of William Henry Day, M.D., late of Manchester Square, London.

## NOTES AND COMMENTS.

### Medical Witness Fees.

THE other day, or to be more precise, on the 15th of the present month, a fine public protest was made by Dr. Shaw in Brighton Police Court. In order "to maintain a principle," as he himself put it, he refused to give evidence until paid a fee of two guineas. A solicitor explained that witness had been paid one guinea, which was the full fee allowed by the scale, and he declined to pay more. As the doctor still stuck to his guns, the Town Clerk hinted that he might be detained by the Court until he complied. Dr. Shaw told the Court he had been put to great inconvenience by being brought into the case, and he objected to being dictated to by the complainant's solicitor. Eventually, however, he allayed the judicial storm by giving his evidence under protest—"and the case proceeded." Would that we had more Dr. Shaws in the medical profession. Were there anything like concerted and persistent action on the part of medical witnesses the Courts would soon learn that the special fees of medical men were just as sacrosanct as those of other folk.

### An Unpaid Fee.

THE present writer is reminded of an unpaid fee in a provincial County Court many years ago. He had been acting as *locum tenens* for a provincial practitioner, and in the ordinary course of practice was called in to see a child who was stated to have been injured by a school-master. An ulcer was shown on the leg in proof thereof, but it did not correspond with the history of the alleged assault, and, from a medical point of view, could not conceivably have been caused in that way. The writer came back several months later for another *locum tenens* post, and just as he was leaving the town was subpoenaed to give evidence by the child's parents in an action for damages. He was kept in the town for several days, at great inconvenience and some pecuniary loss, to give evidence in a trumpery case that broke down ignominiously, and he received no fee whatever. Had he been wise he had refused to give a word of evidence before his fees were paid. Most medical men have to learn this sort of lesson. If we all spoke out and acted like Dr. Shaw, of Brighton, lawyers and magistrates, not to mention judges, would soon accept the position. The key to success, in this as in other matters, is simply united action.

### Operation by a Midwife.

FROM time to time cases are reported which illustrate the inevitable tendency of the certified midwife to assume the rôle of medical practitioner. An extreme instance of the kind was investigated not long since in the

Chester-le-Street police court, where a certified midwife was charged with causing the death of a four-day-old infant. It appeared from the evidence that defendant had delivered the wife of a miner of a healthy male child. She said the child was "tongue tacked," and she would "nick it." She accordingly cut the frænum with a pair of scissors, but so unskilfully that the baby died of sublingual hæmorrhage. Luckily for the midwife, the prosecution took a lenient attitude and merely asked that the case be sent to trial. Counsel for the defence urged that there was no criminal neglect nor intention, a view adopted by the Bench, who dismissed the case, but expressed a hope that it would be a warning to defendant and others. The incident shows precisely how the skilled midwife is apt to develop into the unskilled medical practitioner. It is difficult to see on what grounds leniency is shown by police magistrates to women who deliberately transgress the legal limits of their occupation. One may naturally ask, if a midwife who performs a surgical operation with fatal results is to go scot-free, what offences are likely to be punished under the Midwives Act?

### Jaw Development.

THE amount of caries of the teeth, both primary and secondary, in civilised children of to-day is a matter which is rightly attracting much attention, and it is certain that no universally-recognised cure for the condition is yet forthcoming. It is very proper, indeed, that children in board schools should be taught to use the tooth-brush, but we doubt if this measure of cleanliness will really much affect the alarming amount of decay. In private and public schools where boys and girls use their tooth-brushes night and morning as a routine measure the caries rate is little, if at all, below that of the schools which receive the children of the labouring classes. In a paper read by Dr. Hollopetter before the American Medical Association, stress is laid on the capriciousness of the morning appetite of children brought up in slums, and he asserts that the frequent anorexia of these children is due to their insanitary surroundings. The first step in hygiene, then, is to get children to eat normally by providing them with healthy sleeping accommodation. The next point he dwells on is the necessity of developing the jaws by giving them food which demands hard chewing. He gives many instances of how the jaws, especially the mandible, become larger and more square on such diet, and he holds that adenoids are largely the result of feeding children on sloppy and pulpy foods. Similar views have been put forward by Dr. Sim Wallace, of this country, and we think that they deserve the greatest attention from those interested in this important matter.

## LEADING ARTICLES.

### MEDICAL LAW REFORM.

IF reform of medical law has at length been brought well within the sphere of practical politics, it is at least to some extent due to the fact that the subject has for years been kept to the front by THE MEDICAL PRESS AND CIRCULAR. In taking credit for what this journal has unquestionably achieved, it is not necessary to belittle the services rendered to the cause by professional contemporaries, and those who have devoted personal energies to it. To Mr. Henry Sewill must be given the credit of initiating the movement for a Royal Commission, and it is almost entirely owing to the propaganda that he has for years carried on within the British Medical Association that the Branches have discussed the matter, and carried resolutions urging their Council to action. That body has at last been persuaded to address the General Medical Council, which in its turn has induced the Privy Council to open an inquiry by means of a circular to medical officers of health, into the extent and effects of unqualified practice. Then, the Home Secretary, within the last few weeks, has virtually promised that a Select Committee shall be appointed next Session to inquire into the quack medicine traffic. We have always supported the contention, which has been urged throughout by Mr. Sewill, that any new medical laws based upon an inquiry from which the trade in quack medicines and apparatus were excluded must prove to a large extent futile, since a great part of fraudulent practice is conducted under the cloak of that traffic; and we think that efforts should now be directed to obtain a Royal Commission with the widest necessary scope and powers. A Royal Commission is, of course, merely a means to an end. It presents the only means by which the facts can be set out in a form beyond controversy. A Commission can make plain to all intelligent eyes that the foundations of coarse quackery are simply a mass of undiluted falsehood, a heap of lies, gross as a mountain, open, palpable. Quack practitioners selected from every class, and the proprietors of quack nostrums and apparatus confronted with sworn testimony as to the ingredients and mechanism of their pills, potions, and instruments, would be called upon by a Commission to justify their claims as miracle mongers; and there can be little doubt that the imminence of such an ordeal would alone in itself suffice to frighten out of existence great numbers of these gentry. A Commission would show that whilst legislation might improve the status of the legitimate practitioner, it would confer incalculably greater benefits upon the poor, suffering, and ignorant classes who have most claim upon the guardianship of the State. It has been found easy to frame laws which practically make it impossible for unqualified solicitors to practise under any pretence, and similar laws can be constructed for doctors. With regard to the traffic in quack medicines, and bogus apparatus, if any public prosecutor existed, charged with the duty of putting the law in force, a great deal of this fraudulent, cruel, and murderous

trade could be put an end to under existing statutes. The well-known case tried before Mr. Justice Lawrence at the Lewes Assizes two years ago demonstrated the efficacy of the laws against "false pretences"; whilst numerous cases in the police courts have shown how slight a modification of the Food and Drugs Act is needed to bring within reach of the law large classes of quack medicine vendors. The case for medical law reform is overwhelming; it is the duty of the profession for the sake of humanity, and even in spite of misrepresentation or calumny, to strive with all their might to force it upon the attention of statesmen, and leave upon them the responsibility for the continuance of abuses which, to those who realise their gravity, seem almost intolerable.

## CURRENT TOPICS.

### Candidates for Hope Hospital, Salford, and the Warning Notice.

THE issue of a "warning notice" in the *British Medical Journal* against applications for the senior resident medical posts in the Hope Hospital, Salford, has not had the desired effect. The salary is clearly inadequate for a position of so much responsibility and importance, and the medical profession have been advised to leave the Salford Board of Guardians severely alone. We regret to say, however, that four applications have been made for the vacancy in answer to an advertisement. The names of the three candidates asked to attend the Board, according to the *Manchester Evening Chronicle*, are: Dr. Jos. Rodriques, senior house surgeon, Stockport Infirmary; Dr. H. J. O'Sullivan, of the Lunatic Asylum, Cork; Dr. C. Haslewood, Blackburn. It is indeed unfortunate that any members of the medical profession should thus thwart the endeavour of their brethren to obtain a juster standard of professional remuneration. Possibly the issue of the "warning notice" may not be known to them, and in that case an explanation and a withdrawal may yet be forthcoming. In the face of the Hampstead Hospital notice, however, which was flouted by certain hospital consultants last year, it is difficult to believe that any efficient pressure could be brought upon the candidates for the Hope Hospital appointment, even assuming them to be members of the British Medical Association. At the last moment before going to press, we are happy to learn that none of the three selected candidates appeared before the Board, so that our surmise as to none of them having known of the warning notice was probably correct. We congratulate these gentlemen on their loyalty to the profession, and on the example they have set to others who should have needed no such admonition.

### Improved Housing.

THE Housing Bill, if it survive the Lords, must have far-reaching effects on the health of the community, and is perhaps the most important legislative measure likely to reach the Statute Book for many years. It is difficult, indeed, to estimate the number of ills and diseases which arise from bad housing. As was pointed

out by the Earl of Crewe, in the House of Lords, it is impossible to deal with the problem of excessive drinking so long as people live in intolerable houses. It is no wonder that the decent artisan in many cases prefers the relative comfort of a public-house "snug" to the squalor of his own home. It is difficult to imagine how healthy children could be reared in the surroundings in which many of the respectable poor have to reside. Moreover, in regard to tuberculosis, the settlement of the housing problem will do much to diminish the incidence of the disease. There is little use in attempting to inculcate lessons of personal cleanliness to people who have to live five in a room, and who have to carry every bucket of water up four flights of stairs. How maintain free ventilation in such tenements? If Mr. Burns' Bill does anything to abolish such conditions, and to give our working people a chance of living in cleanly, wholesome fashion, he will have deserved well of his country.

#### The Danger of Sun-Baths.

DURING the past few years various forms of "simple life" have attracted the attention of the public, and among the methods of escape from civilisation which have been advised and practised has been the shedding of clothes and return to nakedness. It has become, in fact, a popular amusement to expose the naked body to the air and the sun, and sun-baths have been vaunted as of great hygienic efficacy. In this country climatic conditions have not favoured this particular form of simple life, but in Germany and in America many people spend whole days in the summer alternately bathing in sunlight and in water. Most of us have inclined to think the custom a harmless, if silly, one, but Professor Grawitz, of Berlin, has discovered a quite imposing train of pathological symptoms arising therefrom. Among the most prominent are dermatitis, tachycardia, and irregularity of the heart. In some cases there was syncope from insufficiency of the heart, and in many there was enlargement of the area of cardiac dullness. Headache and general debility were frequent, and in some persons an unwonted nervous irritability was developed. Professor Grawitz warns the public against the indiscriminate use of sun-baths, a warning in which we are sure all sensible people will join.

#### The War Office and Soldiers' Bad Teeth.

THE restless pursuit of the ideal is apt to lead enthusiasts into situations that are grotesque and ridiculous. Something of the kind seems to have happened in the attitude of our army authorities towards the defective teeth of soldiers. A question asked the other day in the Commons showed that thirteen men of a crack hussar regiment, now under orders for service in India, were rejected as medically unfit on account of their teeth. The sum of £1 per head is granted for dental treatment in these cases, but the cost was estimated at a larger sum, and the men were given the option of paying the difference or of taking their discharge. Three of them paid the money and ten took their discharge. As to the economics of the incident, it would be desirable first to learn who made the esti-

mate, and whether more than one dentist was consulted. Secondly, the value of a trained hussar to the nation must be more than the £3, which we learn from another source constituted the higher estimate. Surely the War Office has made a bad bargain in losing ten trained soldiers for lack of a payment of £20. As to the possible injury to the health of the men, we think it unlikely that men presumably in fine physical condition would within a few years of service in India be incapacitated because of one or two decayed teeth. It would under such circumstances take many years to destroy the digestion and set up the proposed anæmia and other serious consequences often associated with prolonged dental decay. It is, of course, right that soldiers should have their teeth in good order, but there is no need to push a sound principle to absurd extremes. Misapplied science of this fantastic kind costs the taxpayer a pretty penny.

#### Infantile Mortality in Finsbury.

IN the course of a series of able and exhaustive special articles on the London Borough Councils, the *Standard* gives many valuable details as to the public health work in the various boroughs. In Finsbury among other good work, the average infantile mortality has been substantially reduced during the past three years. The deaths of infants under one year of age were 156 per 1,000 births in 1906, 127 in 1907, and 133 in 1908. Up to 1906, for some years a municipal milk depôt, entailing a charge of £500 per annum on the rates, had been kept up. It was, however, found that the great bulk of the 3,000 children born annually in the borough were not brought under the influence of the depôt. It was therefore decided to close it, and to formulate instead a scheme for health visitors. Two lady sanitary inspectors and a health visitor were specially appointed for the work. Infants of poor parents are now visited as soon as the birth is notified, and advice is given regarding the feeding and rearing of the child, whilst cases requiring surgical aid, food, clothing, etc., are brought to the notice of established charitable organisations ready to co-operate in the good work. The mortality tables just cited demonstrate the result. The scheme is costing the ratepayers less than a fourth of the previous outlay on the milk depôt. The first experiment of this kind was made by Alderman Broadbent during his mayoralty at Huddersfield, and it has yielded similar satisfactory results wherever intelligently carried out, and deserves imitation in every rural and urban district throughout the country.

#### Preservatives in Cream.

THE report to the Local Government Board by Dr. Buchanan on the preservation of meat, discussed in these pages a few weeks ago, disclosed the fact that formalin preparations were often grossly misused to overcome foul odours and other signs of putrefaction, so that meat really unfit for food might be placed upon the market. It is satisfactory to find, according to the report to the same authority by Dr. J. M. Hamill, that similar abuses do not seem to prevail in the case of cream, although the report shows that stringent limitations of the use of boron compounds as preservatives

are desirable, these, in excessive quantity, being capable of acting deleteriously on health. The difficulties of distributing cream fresh every day renders the use of preservatives necessary, and Dr. Hamill does not object to these, but insists that their presence and quantity should be always notified. A Departmental Committee declared that boric acid should not be permitted in amounts exceeding 0.25 per cent., whilst the cream trade affirm that no limit lower than 0.5 per cent. is sufficient. This difference of opinion has led to inconsistency in the administration of the Food and Drugs Acts by different local authorities, and has rendered the present position of the cream trade unsatisfactory, both as regards sellers and buyers. The question of cream is comparatively small and unimportant in the vast field of the national food supply. When this field is minutely surveyed, the difficulty of guarding the people against fraud and adulteration seems almost insuperable. No doubt even partial enforcement of existing laws does act as a deterrent upon many traders who would otherwise be entirely unscrupulous; but existing evils will never come to an end until the moral qualities of the trading community become raised, and the conscience of the dealer instinctively revolts against the carrying on of a dishonest traffic which at the same time inflicts damage upon the health of its victims. It seems a deplorable thing that at this period of twentieth-century civilisation society should be still obliged to arm itself against a host of bad citizens bent in so many directions of preying upon and misusing it.

#### Malarial Prevention in India.

SIR RONALD ROSS publishes in a leading paper an able letter on this subject. He argues strongly in favour of mosquito reduction for prevention of malaria in towns and crowded areas, although he believes that in rural areas quinine prophylaxis, assisted, if possible, by screening, is more appropriate. The measure he advocates tends to rid a town not only of malaria, but of other mosquito-borne diseases, one of which—filariasis—abounds in parts of India, and at the same time it does away with one of the worst pests of tropical life. Sir Ronald describes the difficulties of quinine prophylaxis, the distribution of the drug, and continued persuasion of the people to take it. He combats the view that quinine treatment is less expensive, and supports his opinion by reference to the results of the anti-mosquito campaigns in the Panama Canal zone, Ismaila, and elsewhere, results which were recently described in these columns. Sir Ronald Ross's letter owes its origin to the fact that the Indian Government has ordered a conference on malaria, which is to be held at Simla in October. He pleads for full discussion before a properly-constituted tribunal, and suggests that it is necessary to include engineers among members of the Conference, seeing that medical members' knowledge of drainage and public works must obviously be restricted. Sir Ronald Ross has made out a strong case in favour of his recommendations; it can hardly fail to be treated with respect by the Indian Government, to which his letter obviously is indirectly addressed.

#### Skin Radiation and Heatstroke.

SOME interesting observations upon heatstroke in the Royal Navy stokeholds have been communicated by Staff-Surgeon Oswald A. Rees. The production of heat, he points out, is due to chemical agency, whereas loss is controlled by physical causes. The small animal loses heat much more rapidly than a large one, and it is found that a small Navy stoker will lose heat more rapidly than a fat one, from the fact that fat has only half the conductivity possessed by muscle. The metabolism of a man of 180lbs. compared with another of 120lbs. is as 3 to 2, but, on the other hand, the fat man loses heat at a much greater rate by water evaporation. The negro has a distinct advantage in the stokehold, because a black skin radiates heat better than a white one. Another interesting fact pointed out by Staff-Surgeon Rees is that men working in the bunkers are not more subject to heatstroke than those working in the stokehold, although the bunker is by far the hotter place. The explanation is that the men in the bunkers become at once covered with a thin layer of coal-dust, whereby the radiating power of the skin is increased. Clothing impedes heat-loss, but much depends on its absorptive power. Over-feeding predisposes to heatstroke, for which the best remedy is the ice bath. There is still a good deal to learn about the important subject of heatstroke, and it is encouraging to note that the matter is being scientifically investigated at first hand.

#### A New Medical Society in Dublin.

IT may be thought by many that there are already enough medical societies in Dublin, and that any increase in their number must injure the vitality of those existing. The Society whose advent we announce this week, however, does not seem to come into conflict with any of the existing societies or clubs, and is, moreover, conceived on somewhat original lines. Its membership is confined to licentiates of the Apothecaries' Hall, an ancient corporation which has shown many signs of renewed activity in late years. Its title is to be "The Medical and Scientific Society of the Apothecaries' Hall," and its object is to invite recognised authorities—medical, scientific, legal—to deliver lectures on subjects likely to be of interest to licentiates of the Hall and other medical men. It is intended that meetings should be held each month during the winter session. The promoters of the Society hope that addresses to medical audiences on subjects not directly included in their professional studies will stimulate thought, and will have a good educational influence. It is not contemplated that any subscriptions will be required to carry on the work of the Society. The plan seems to us a fruitful one, and we are sure that many outside the number of the licentiates of the Hall will watch its development with sympathetic interest.

#### Radium and the Radium Institute.

THE price of radium appears to be rising instead of becoming less, as it was hoped would be the case. Some years ago radium was obtained

from the famous Austrian Government mines at Jachimsthal, Bohemia, at a cost approximately of some £600 per gramme. On the other hand, a single gramme recently obtained from that source is stated to have cost several thousand pounds. The British Radium Institute are to have 7½ grammes, which Lord Iveagh and Sir Ernest Cassell have ordered for it, and which is to be extracted from Cornish pitchblende at a cost averaging about £4,000 per gramme. It is, of course, possible that under the exceptional circumstances of the case the institution of a special institute is the most practical way of working out the therapeutic properties of radium. At the same time it is to be hoped that the doors of the institution will be thrown open freely to accredited scientific workers. Medicine is not an exact science, and the light of discovery not infrequently flashes from unexpected quarters. Anything like a "corner" in any branch of scientific medical research is out of touch with the breadth and catholicity that stamp great minds seeking after truth.

### The Peculiar People and the Public Prosecutor.

THE death of a member of that curious sect the Peculiar People (one of whose tenets is the substitution of prayer for skilled medical ministrations) once more calls attention to the legal position of persons implicated in such transactions. Elsewhere in our columns a short account is given of the death, at Southend, of a woman belonging to the sect in question. The cause of death was intestinal obstruction, and the Coroner stated his confident belief that the unfortunate woman's life would have been prolonged, if not saved, by surgical operation. Addressing himself to those who had attended deceased during her illness, he told them they were responsible for her death. Finally, according to the newspaper report, he said that but for the fact that the woman's complaint was a complicated one, he should have sent the depositions to the Public Prosecutor. It is difficult to follow this line of argument, for most folk would probably maintain that the more complicated the case the grosser the offence of treating it with such spiritual remedies as anointing with oil and the "laying on of hands." The Public Prosecutor would do well, in the interests of the community, to look closely into these cases, as well as those of the Christian Scientists, who agree with the Peculiar People in the blasphemous substitute of religious rites for established medical treatment. The difference between the two sects is chiefly social. The Scientists are wealthy and live in the West-end, while the Peculiars are poor and dwell in the East-end. Both sects require the services of the Public Prosecutor from time to time, following those of the coroner.

### PERSONAL.

THE Lord Mayor of London, Sir George Truscott, on Saturday last laid the foundation stone of St. Mary's Hospital for Women and Children, Plaistow.

MR. WILLIAM BROWN, B.Sc., Lecturer in Electro-Technology at the Royal College of Science for Ireland, has been appointed to the Chair of Physics in the College.

AFTER thirty years' service on the staff of the Adelaide Hospital, Melbourne, Dr. J. C. Verco has resigned his position as honorary physician, and has been appointed consulting physician to the institution.

THE Earl of Stamford will preside at a reception to members of the Child Study Society, on Thursday, October 7th, at 90 Buckingham Palace Road, London.

DR. GEORGE WILSON, who for thirty-six years has been medical officer for the Solihull District, and Mid-Warwickshire Joint Sanitary Authority, has resigned on account of failing health.

MR. J. BLAND-SUTTON, F.R.C.S., has made a donation of £1,000 towards the fund which is being raised for the purchase of an athletic ground for the medical school attached to the Middlesex Hospital.

SIR VICTOR HORSLEY, F.R.S., will present the prizes to students of the Royal Dental Hospital of London, on Wednesday, October 20th, at the Royal Institute Galleries, Piccadilly, London, W.

THE Medical Congress, which has just finished its session at Budapest, has been graced by the presence of no less than 800 women, whose special committee was presided over by an accomplished lady, Madame Bokáy.

DR. ERNEST T. ROBERTS, certifying factory surgeon for the district of Keighley, has been appointed by the Glasgow School Board as chief medical officer for the inspection of children under the Education Act of last year.

AT Zurich, recently, a number of friends and former pupils assembled from all parts of the world to celebrate the seventieth anniversary of Professor George Lunge, the well-known authority in chemistry. Dr. Lunge, who was born in Germany, is a British subject.

APPLICATIONS for tickets of admission to St. Paul's Cathedral at the annual medical service of the Guild of St. Luke should be made to Dr. C. S. A. Farrer, 1 Harley Street, London, W. The service will be held on the evening of Wednesday, October 20th.

LAST week Miss Stebbington, a nurse on the staff of the North-Western Fever Hospital, was complimented on her courage in securing the capture of a street thief, whom she pluckily pursued. The accused snatched a gold watch and chain, and was sent to three years' penal servitude.

A MOVEMENT is on foot for the purpose of making some appropriate recognition of the long and distinguished services of Professor John Cleland, on his retirement from the Chair of Anatomy in Glasgow University. A circular letter has been sent to all graduates, and the form of recognition will depend ultimately on the amount subscribed.

THE Rev. E. L. Adams, of Scarborough, has bequeathed £4,000 to the Manchester Royal Infirmary for a new ward; £4,000 to the Victoria University, Manchester, to found a scholarship; £4,000 to the Scarborough Hospital for the permanent endowment of a children's ward, and £500 to the Smedley Memorial Hydropathic Hospital, Buxton, for the endowment of a ward. The three first items were reduced before the death of the testator by £500 each, because of the new estate and death duties of the Budget, which he regarded as "most unwise and unjust."

# A CLINICAL LECTURE

ON

## TWO CASES OF INTESTINAL OBSTRUCTION. (a)

By J. RUTHERFORD MORISON, M.B., F.R.C.S.,

Lecturer in Surgery in the University of Durham; Senior Surgeon to the Royal Victoria Infirmary, Newcastle-upon-Tyne.

FOR the notes of the first case to which I wish to draw your attention I am indebted to my late House Surgeon, Dr. Walker.

*Case 1.*—A man, æt. 56, was admitted to the Royal Victoria Infirmary on February 14th, 1909, very ill with acute intestinal obstruction. As soon as I saw him I recognised an old friend whose past history, though it may or may not have any bearing on his attack of obstruction, is full of interest. For years—not less than 15—he had come more or less regularly for demonstration to generations of students as a typical example of leucoplakia which had followed syphilis, and was associated with the abuse of tobacco and alcohol. From time to time his tongue had been obstinately ulcerated, and the probabilities of cancer developing there had frequently been discussed. All sorts of lotions and paints and medicines were tried in the hope of improving his tongue, but it is safe to say that very little benefit had been derived from any of them, and that when the ulcers healed it was more because he smoked and drank less than from any remedies he had been using.

Ten years ago (April, 1899) I removed his left testicle for septic broken-down syphilitic gummata.

Four years ago he was advised to try X-rays for his tongue, and it is of interest to note that this somewhat extraordinary prescription not only gave him relief from all the discomforts which he had in it, but that all the ulcers healed, and the condition of the tongue generally was so much improved that I was surprised to see it.

To return to his present illness the history was:—

That for about five years he had had troublesome constipation with occasional attacks of pain in the left hypochondrium, but no vomiting. Since August, 1908 (six months ago), the pain had been almost constant, and had frequently prevented him from sleeping at night, and was accompanied by occasional vomiting. For the last two months he had frequent attacks of pain accompanied by loud rumblings, during which he had been unable to pass wind or motion. He also had during this time frequent diarrhoea with slimy, offensive blood-stained motions. He had been steadily getting thinner, but had no record of his lost weight.

For five days previous to admission the pain in his left hypochondrium made him shout out and vomit frequently. He had passed a motion after an enema, but had voided no flatus, and felt very ill.

On admission (February 14th, 1909) he looked ill. His visible arteries appeared to be much thickened. His temperature and pulse were normal.

Examination of the hernial sites and rectum revealed nothing. The abdomen was swollen and tympanitic, and the distension was most marked on the right side. During a spasm of pain the distended cæcum could be mapped out and felt to harden, and the ascending and transverse colon also stood out prominently during the paroxysm. The pain was always referred to the left hypochondrium, and tenderness was present on pressure there.

The diagnosis made was intestinal obstruction due to a malignant stricture in the splenic flexure of the colon with hypertrophy and distension of the cæcum and colon, proximal to the stricture, the contents being actively virulent in consequence of colitis and retention above it.

The treatment suggested was (1) *Lavage of the Stomach*. (The stomach contents were to be washed out as frequently as required to prevent vomiting.)

(2) *No food was to be administered by the mouth, but by enema*. (Every two hours 1 pint of equal parts of fat beef tea and milk with one teaspoonful of salt and half an ounce of whisky were to be given slowly through a rectal tube and raised funnel.)

(3) *Small doses of opium to relieve pain*. (When the patient was restless or in pain, 10 min. of liq. morphia hydrochloratis in 1 dr. of aq. menth. pip. was to be given.)

(4) *Heat applied to the Abdomen*. (A hot poultice of linseed meal, large enough to cover the whole abdomen, was to be kept on for one hour, then to be replaced by heated cotton wool for seven hours, when the poultice was to be repeated.)

*After progress.*—No material benefit followed this treatment, and the stomach contents developed a definite faecal odour.

Two days after admission (February 16th), the failure of medical treatment to give relief, I made a small incision in the right iliac fossa, drew forward a piece of the anterior wall of the cæcum, opened it, tied a Pauls' tube in for drainage, and fixed the whole with harelip pins (cæcostomy).

Two days later, after abundant discharge from the tube, the patient was entirely relieved, and by injections through the cæcostomy opening and from the rectum the colon was cleansed and the obstruction was localised in the splenic flexure.

Second operation March 13th, 1909 (a month after cæcostomy). The abdomen was opened through the left rectus muscle and a growth was found in the splenic flexure of the colon. This could not be drawn forward till it had been mobilised by division of the peritoneum forming the upper layer of the meso-colon, but division of this allowed the greater part of the transverse and descending colon as well as the splenic flexure to be lifted out on to the abdominal wall. Enlarged hard mesenteric glands were felt in the mesentery

(a) A Clinical Lecture delivered on June 10th, 1909, at the Royal Victoria Infirmary, Newcastle-upon-Tyne.

near the growth. Half of the transverse and descending colon with a corresponding portion of mesentery was excised with the growth, the ends of the bowel were closed by sutures, and a large lateral anastomosis was established by sutures between the remains of the transverse and descending colon.

On March 27th (fourteen days later), after free irrigation of the colon the cæcostomy opening was closed, and on April 8th (twelve days later) the patient left the Infirmary with his wounds healed and feeling well.

Note in the growth removed (exhibited) the tight stricture looking from the outside as if a piece of string had been firmly tied round the gut. Note also the hypertrophied and dilated bowel above the pale, thin, contracted colon, and a quantity of fat in the pucker round the growth. This is typical of adenocarcinomatous stricture of the intestine.

Patient, æt. 35, admitted to private hospital on June 11th, 1909. She was in her usual good health till four days before, when she developed a cough, coryza, temperature 100.6°, and slight abdominal pain. These symptoms persisted, but her medical adviser, herself and friends all regarded the illness as in no way serious till 11 o'clock on the day of admission. She was then suddenly seized with a severe abdominal pain, vomiting and collapse, and the pain and vomiting had persisted till her admission five hours later. (She was driven twenty-one miles lying in a motor car.)

On admission she was collapsed, her face and hands were a bluey red colour and cold, her pulse 82, though so feeble as to be scarcely perceptible, her tongue dry, brown and bile-stained, her temperature normal. There was no history of any previous abdominal illness whatever.

On examination there was nothing discoverable in any of the hernial sites or from the rectum or vagina. The abdomen was distended and slightly tender all over, but nowhere rigid. During a paroxysm of pain, which was very severe, the intestines could be seen to distend and felt to harden and to assume the ladder pattern characteristic of an obstruction involving the small intestine. The paroxysm appeared too end with a gurgle in the right iliac fossa.

The diagnosis arrived at was:—Acute intestinal obstruction from block of the small intestine, with strangulation of a considerable area of the gut, and as a possible cause Meckel's diverticulum.

The patient had been conveyed direct from the motor to the operating table, and a quarter of an hour after her admission and after her stomach was washed out, she was anaesthetised for operation.

**Operation.**—The abdomen was opened in the middle line by excision of the umbilicus, and the diagnosis of acute intestinal obstruction was confirmed by the escape of a quantity of blood-stained serum and the appearance of congested distended coils of small intestine. The cæcum was found to be pale, contracted, and empty, and the coil of ileum entering it in a similar condition. This was followed upwards till the point of obstruction, between two and three feet up the ileum, was encountered. Above this the bowel was large, tense, with a quantity of fluid contents, bluish and congested, below it small, empty, and pallid. The obstruction was caused by something fixing acutely and kinking the ileum on the outer side of the cæcum and ascending colon, and on separating this adhesion pus escaped. This

was at once mopped up and the bowel was set free. After cleaning away the pus a gangrenous perforated appendix was turned out of the abscess cavity and excised. The abdominal wound was closed except at the lower end, from which a drainage-tube from the pelvis emerged.

Her recovery up to date has been so straightforward that I may—almost four days after the operation—say she is well. (Her recovery subsequently was uninterrupted.)

These cases serve to illustrate the two most important divisions of intestinal obstruction, viz., acute and chronic, and give me the opportunity of offering certain remarks upon diagnosis and treatment.

Before entering into further detail I must emphasise the need for examination of the hernial sites and of the rectum in all such cases. It is impossible I should overrate the value of this because so many times the routine examination has discovered for me an unsuspected hernia or an obstruction palpable from the rectum. The diagnosis is then so easy as to require only ordinary care, but it must be recognised that a diagnosis may be so difficult as to be impossible with the greatest care and extraordinary skill.

In every case of acute sudden abdominal pain attended by vomiting, this question has to be answered, Is it obstruction?

There is a Trinity of signs on which the greatest reliance may be placed in answering this question. If the patient has severe griping pains, inability to pass flatus, and there is evidence of increased peristaltic intestinal movements, a diagnosis of intestinal obstruction is safe. If these three signs are not all found in company some doubt must be felt. Text-books still maintain the tradition that intestinal obstruction means inability to obtain a motion of the bowels, and this teaching is responsible for many serious errors in diagnosis, for it is not true. It is possible for a patient to pass no motion for weeks, but that does not constitute intestinal obstruction. It is possible for a patient with intestinal obstruction and the three signs described to have a copious evacuation. If the bowel below an obstruction contains fæces at the time of the attack these are likely to be expelled if an enema is administered, but the evacuation fails to bring with it any flatus. This is the crucial test, *the obstruction to flatus*. It is this obstruction that starts the agonies of intestinal obstruction. When flatus is arrested a condition is started in the intestine resembling panic in a crowd, and like this tending only to terminate in disaster. The next questions to be answered are, "Where is the block?" and "What is its nature?" These questions have to be answered for each individual case, and may present grave difficulties.

In the first case the diagnosis was easy. We were able to say that the patient had intestinal obstruction at once. Where was the block? The age of the patient suggested malignant stricture of the colon, for this is the most ordinary cause of intestinal obstruction in patients over 40, but the stricture is usually in the sigmoid flexure or in the rectum.

The constipation with painful rumblings and occasional "diarrhoea" support this view. "Diarrhoea" is Nature's cure for the obstruction. When the bowel above a stricture is irritated by solid fæces which cannot pass, its mucous membrane inflames, secretes large quantities of fluid

in which the hard faecal masses are dissolved, and these are then enabled to pass through the stricture accompanied by mucus and blood-stained discharge from the inflamed colon. The rumblings are also caused by Nature's effort to overcome the obstacle by increased peristaltic contractions of the bowel, and are sometimes so loud as to be heard at a considerable distance from the patient. The pain in this case was felt, as it may be, in the position of the obstruction, and this probably depended upon its long duration. I have frequently observed that in the early hours or days of abdominal pain the patient has been unable to localise it. Later and after some experience the power to do this increases, till finally, when it has been of long duration, the exact spot affected by disease may be picked out as the seat of pain. This looks as if the visceral nerves required education for localisation, and if the history of five years' duration be correct they had abundant opportunities. The stricture was due to cancer, and some of you may wonder at my belief that this cancerous stricture could have been there for five years before leading to dangerous obstruction. Such a statement would have surprised me a few years ago, but I have now learned concerning malignant disease of the large bowel that on the one hand it may be the most malignant of malignant growths, that a small cancerous ulcer may be followed in a few weeks by secondary deposits in the peritoneum, mesenteric glands, liver, and by death, or, that on the other, it may grow so slowly as to take years to kill its victim. One patient under my care, and on whom I made a post-mortem examination, had an advanced malignant growth of the rectum diagnosed twelve years before his death, and during his last seven years' of existence all faeces were passed through a colostomy opening. The disease had never extended beyond his pelvis, death was caused solely by extension into his pelvic structures, and until the microscope had settled that this was a typical columnar-celled carcinoma I felt some doubt as to the diagnosis. A single case proves nothing, but several of my patients have lived for more than five years after a colostomy for growths in the sigmoid and colon so advanced as to have appeared to be unfit for removal. I can therefore ask you with some confidence to accept the history of five years' pain in the splenic flexure of this man's colon as an indication that he had malignant disease there for that time.

You will note the point that I have previously emphasised concerning the enema, that though a stool followed its use no flatus was passed, but this is typical of obstruction either in the small or the large intestine and has no localising value. The chronicity of his illness also suggested a block in the large intestine, for chronic obstruction is usually due to this, and acute obstruction to an interference with the small intestine, though there are so many exceptions to this rule as to make it of small practical value.

The point to which we attached the greatest importance was based on a physical sign. It was the enlargement of the right side of the abdomen by a portion of distended intestine which we believed to be the caecum. If it is certain that the caecum is distended this evidence alone suffices. The block will then be found in the colon as it was in this case. That the colon would be hypertrophied, dilated and inflamed above the ob-

struction was easy to prophecy on general principles, and we know that it always is.

You are likely to wish to know my reasons for not operating at once in this case as I did in the next, and they are these.

It was impossible to do a radical operation for removal of the growth and restitution of the colon, the bowel being distended by septic contents, with any reasonable chance of success. A painful experience has taught us that however successfully the operation may be performed under such circumstances the patient is almost sure to die.

Experience has also taught us that the methods we adopted sometimes suffice temporarily to relieve the obstruction and allow, after the bowel has been emptied, of a radical operation. If this cannot be effected three operations instead of one are necessary, and the increased risk of waiting is counterbalanced by this consideration.

Our first method failed, and we were forced to operate, first for drainage, second to remove the growth, finally to close the drainage opening.

In the second case the diagnosis of acute intestinal obstruction, the block being in the small intestine, was based upon physical signs which could not be misunderstood. We ventured further, and in doing so made a mistake. There is fortunately nothing to regret, for it was not detrimental to the patient, and in order to make any advance in surgery or in anything else it is necessary to venture as far as possible for only such exercise is a sufficient stimulus to the gaining of new knowledge.

How did the mistake occur?

First in an insufficient history. It is likely that if the story of the preceding day's illness had been fairly unravelled a clue as to the appendix would have been obtainable.

Second and chiefly from a belief in the probability that such a sudden and serious illness was due to strangulation of a large portion of the small intestine that it was unlikely to be due to anything but an encircling band, and that there was no history of any illness likely to produce such a band. From this case we learn that obstruction by a kink with vascular disturbance in the bowel above may, just as a strangulation will, give rise to blood-stained fluid in the peritoneum and severe collapse.

Before concluding, I would like to remark concerning treatment, that the results in cases of acute obstruction of the small intestine are little if any better than they were twenty years ago, whereas the results in chronic obstruction, especially affecting the large intestine, have enormously improved. Why is this? It is because operative *technique* has made such strides during that time and operative skill has a considerable influence on the statistics of colon obstruction. Operations for colon obstruction mostly require the difficult operation of resection for their radical cure, and this has been perfected during that time. But operations for the radical cure of small intestine obstruction have not been influenced much, if at all, by surgical progress. They are nearly all simple—e.g., the division of a band, the separation of adhesions, the withdrawal of a strangulated loop, and these could be done as successfully twenty years ago as they can be now.

The lesson we learn is, that early diagnosis and immediate operation are of far greater importance than operative skill, and no improvement in

results can be expected until this has been acknowledged and acted upon. Then patients will recover from acute intestinal obstruction as they now recover after operations for strangulated hernia.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by R. Atkinson Stoney, F.R.C.S.I., Visiting Surgeon to the Royal City of Dublin Hospital. Subject: "Cancer of the Tongue."

## ORIGINAL PAPERS.

### RECURRENT HÆMOPTYSIS IN THE NON-TUBERCULAR;

#### TWO ILLUSTRATIVE CASES.

By JOHN HAY, M.D., M.R.C.P.LOND.,

Assistant Physician, Royal Infirmary, Liverpool;  
late Physician, Hospital for Consumption and Diseases of the Chest.

EXPECTORATION of blood is an alarming and arresting experience for a patient, and not infrequently a most valuable cue to the medical attendant. While it is the rule to find no difficulty in satisfying oneself as to the cause for the bleeding, there are occasionally instances where the pathology of the condition is anything but obvious.

A true hæmoptysis or a genuine expectoration of blood from the lungs signifies, as a rule, one of two conditions—pulmonary tuberculosis or valvular disease of the heart. The presence of heart disease can be recognised without difficulty; and as valvular disease is very rarely found in association with pulmonary tuberculosis, the recognition of undoubted cardiac mischief in any patient almost justifies the exclusion of tubercular infection. There are, however, many cases where it is not easy to exclude the tubercular origin of an hæmoptysis. Absence of physical signs and symptoms does not negative such an origin, nor does the freedom of the sputum from bacilli.

Hæmoptysis may be the first and only sign of phthisis, and I believe it is a good practical rule to view as tubercular in origin every case of undoubted hæmoptysis when some other easily ascertainable cause for the bleeding cannot be demonstrated. If, after careful examination and investigation, doubts still remain, they should, when possible, be put still further to the test by some of the more recent methods of inquiry initiated by Calmette, von Pirquet, and Moro, or the blood examined for the presence of the tubercle bacilli in the manner described by Rosenberger and Forsyth, who have proved that, with rare exceptions, the bacilli can be found in carefully prepared blood films obtained from patients with pulmonary tuberculosis.

In each of the two cases which I record, recurrent or intermittent hæmoptysis was a feature. Both patients presented some difficulty in complete diagnosis, and several points of interest in relation to recurrent bleeding from the lungs.

CASE I.—Woman, æt. 45, suffering from angio-neurotic œdema and recurrent hæmorrhage from the lungs and kidneys.

No history of any similar condition in either parent. When 14 years old, and again at 18, was attacked by acute rheumatism. She is still liable to occasional rheumatic pains. In 1899 she had double pneumonia, and it was subsequent to this that she first began to be afflicted with paroxysmal attacks of circumscribed œdema. In the last ten years these attacks have been frequent, and hardly a month has passed without one or more areas of skin

having been swollen and œdematous. The first, affected the left arm and hand; these became greatly swollen and slightly reddened, and, in addition, felt hot and itchy.

The portions of the body which have been involved at different times are the arms, forearms and hands, the thighs, legs, ankles and instep; at other times the ears, lips, skin beneath the chin, and the eyelids, either singly or both simultaneously. When the latter occurs it results in complete disappearance of the eyes. The face, the back of the wrists, and the instep are the areas most frequently involved.

The œdema is circumscribed, and not usually symmetrical; it is hard and solid, and does not cause pain unless pressure is applied. Pitting can sometimes be obtained when the œdema of the area is extensive and the larger part of the limb involved; movement causes pain, and necessitates the use of a sling. Severe attacks last three or four days, and the patient has to go to bed; on such occasions there is nausea and troublesome retching, but no actual vomiting, no diarrhœa, and no colic.

A purpuric rash has never been observed. The cause of the attacks, so far as it has been possible to decide, has generally appeared to be some indiscretion in diet—cold meat or stout for supper, vinegar or rich sauces, sardines, tinned meats, and wines of any kind, especially claret, have all on occasion proved the exciting factor; on the other hand, mental worry or overwork and want of sufficient rest in bed seem to have initiated an attack. There has never at any time been any epistaxis, hæmatemesis, or enlargement of the spleen.

This case obviously belongs to the group of œdemas termed variously, Quincke's œdema, angio-neurotic œdema, giant urticaria, and acute circumscribed œdema. The chief characteristics, as defined by Osler, are, "the occurrence of local swellings in various parts of the body—face, hands, arms, legs, genitals, buttocks, and throat"; "associated with the œdema there is almost invariably gastro-intestinal disturbances, colic, nausea, vomiting, and sometimes diarrhœa," and "a strongly marked hereditary disposition." In my case, in addition to the features already described, recurrent hæmoptysis and recurrent hæmaturia were noted.

The hæmoptysis dated back nine years, and was always associated with the appearance of circumscribed œdema. The blood came up in clots, and was usually unaccompanied by pain or dyspnœa. The most alarming attack of hæmoptysis occurred a year ago. The patient, on rising, felt in good health and started off for Blackpool, where she had arranged to spend the day. Œdema of the face and dyspnœa came on suddenly while the patient was on the way down to Exchange Street Station. When in the train the dyspnœa became rapidly worse and a free hæmoptysis occurred; the blood expectorated was in clots, and amounted to several ounces. She thought she was dying. The only other occupant of the carriage was a lady, who also came to the conclusion that death was imminent, and was so much disturbed that at the first stop she sought another compartment, leaving the sufferer to fend for herself. The dyspnœa and hæmoptysis persisted throughout the day, and in the evening, after returning home, she was still expectorating clots of blood. By this time the eyes were almost closed by the œdema of the lids.

On examining the chest, there was dulness over the left lower lobe, the breath sounds were deficient, and there were numerous medium-sized râles, indicating that the hæmorrhage originated in this area of the lung. This attack was more

severe than any she has experienced, and necessitated her staying in bed for a week; the hæmoptysis slowly diminished, and the chest became normal, with the exception of a few bronchitic sounds. The sputum has been examined more than once, rather as a matter of form than anything else, but no tubercle bacilli have ever been demonstrated.

Hæmaturia first occurred about the same date as the hæmoptysis, and at first used to recur every few months; as with the bleeding from the lungs, bleeding from the kidneys was always synchronous with the appearance of circumscribed œdema of the face or limbs. Previous to the last attack, which occurred a few weeks ago, there had been no sign of hæmaturia for four years. This last attack persisted for some days; the urine appeared red, and the blood was obvious to the naked eye. There are still a few blood cells in the centrifugised urine, but no casts.

The repeated hæmoptysis and hæmaturia show that there must have been in this patient a recurrent liability not only to the transudation of plasma but also of blood. This latter is most unusual, and was not noted in any of the cases described by Osler, Milton, Mendel, Halsted, and others.

It is very generally agreed, however, that there is a close relationship between Henoch's purpura and these cases of Quincke's œdema; now in Henoch's purpura the recurrent permeability of the vessels to blood is a recognised feature. In the cases described by him, among other characteristics, intestinal hæmorrhage was the rule, and hæmaturia complicating acute nephritis was occasionally met with.

This case, in its liability to hæmoptysis and hæmaturia, may therefore be considered to stand as a clinical link between Quincke's œdema and Henoch's purpura.

The treatment has consisted in strict regulation of the diet and habits, and the exhibition of the carbonates of magnesium and bismuth, together with the bicarbonate of soda, all in large doses. In addition, for the last three years she has taken calcium salts at intervals. She has learnt by now that disobedience is nearly always followed by another outbreak of œdema, and there is no question that the liability to the attacks and their severity is much lessened.

CASE II.—Male, æt. 32. Recurrent hæmoptysis occurring in patient with apparently sound lungs. There is no history of any serious illness until seven years ago, when he suffered from acute lobar pneumonia affecting the right side of the chest, after which he expectorated a quantity of pus.

For the last six years, with the exception of recurring attacks of hæmoptysis, he has been in excellent health. No history of syphilitic infection or alcoholism can be obtained. His weight has not varied and there have been neither night sweats nor pyrexia. Tubercle bacilli were not found in the sputum. The heart is normal in every respect.

The attacks of bleeding were usually of a few days' duration, when he would spit up from one to one and a half pints of red, slightly frothy sputum, containing clots. Between these attacks of hæmoptysis there was neither cough nor expectoration.

At first the hæmoptysis occurred every three or six months, but for the last two years they have been much more frequent. On January 12th he was examined by a colleague at the Royal Infirmary in order to discover the meaning of these recurrent bleedings, who reported that he could find no evidence of disease in the chest, and passed him on to the X-ray department. Dr. Holland's verdict was, "absolutely nothing abnormal to be

FIG. 1.

FIG. 2.

made out with lungs or heart or vessels, etc., in any position, no evidence of heart enlargement or alteration in shape." He was then transferred to Dr. Hunt, in the throat department, who reported that there was no lesion in the throat or nose which would account for the hæmoptysis. On the following day I also examined him, and was unable to find anything abnormal with the chest.

On January 29th he was suddenly attacked again by hæmoptysis, and every three minutes or so he expectorated red frothy blood unmixed with pus. The physical signs in the chest were now marked and unmistakable. There was comparative dullness over the whole of the right lower lobe from apex to base, limited anteriorly by the great fissure. The dullness was most pronounced towards the base. The breath sounds were feeble over the dull area; the vocal fremitus and vocal resonance were diminished, and numerous medium-sized crackling *râles* were plainly audible over the 8th, 9th, and 10th spaces. The rest of the chest was normal. He was admitted to Dr. Bradshaw's wards in the Royal Infirmary, who kindly put a bed at my disposal. While in the Infirmary the sputum altered in character and became purulent, and simultaneously the temperature rose to 102.6° F. The pyrexia persisted for a week and then subsided; since when the temperature has been normal.

During and after this period of pyrexia the cough was paroxysmal, and on several occasions the strain of coughing started a fresh attack of bleeding. It was also observed that bending forward and leaning the head over the left edge of the bed was immediately followed by cough and the free expectoration of pus and blood. This combination of physical signs pointed definitely to the presence of a cavity in the lower lobe, and to the probability of the hæmorrhage having originated there, and having caused some blocking of the main bronchi of that lobe. While under observation, the dullness slowly cleared up and the breath sounds became more audible, but at no time were the classical signs of cavity ever distinguished. Before his discharge on April 8th the cough and expectoration had practically ceased, although there was still some impaired resonance at the base.

Perhaps one of the most interesting points about this case is the result of the various examinations by the X-rays. The first revealed nothing, but the second, on February 24th, during the persistence of the hæmoptysis, and previous to the incidence of pyrexia, was most illuminating. The photograph shown in Fig. 1 was taken on that date. There, it is obvious that in the centre of the right lower lobe there is a cavity *c*, half filled with blood; the horizontal surface of the fluid is easily seen dividing the cavity into two parts, the upper half clear and bounded by a thin dark line, the lower half full of dark opaque blood. Passing from this shadow, there is another running up to the root of the right lung.

The second photograph, Fig. 2, was obtained after the cessation of the expectoration, and just before the patient's discharge. It is clear that the lower part of the lung is still not quite normal, but the cavity *c*, which in Fig. 1 can be seen half full of blood, is here well defined and obviously empty. Judging from the clearness of the spaces above the cavity, it is probable that there is some compensatory emphysema in the parenchyma of the lung surrounding it. There is obviously no thickening of the pleura, and any fibrosis which is present is seen towards the root of the lung and around the cavity.

He was examined again by Dr. Holland on April 28th, when the lower lobe was found to be clearer towards its extreme base. Stereoscopic

X-ray photographs have been taken which clearly demonstrate that the cavity is nearer the posterior than the anterior wall of the chest, and is placed posteriorly to the bronchus running down from the root of the lung.

It is remarkable that on examining the chest by palpation, percussion, and auscultation no physical signs indicating the presence of this cavity can be made out. Apart from the evidence afforded by the X-rays, on examining the chest there is nothing to suggest that within an inch or two of the chest wall there is a dry chamber communicating with a bronchus.

I take it that, as a complication or sequel to the acute pneumonia, an abscess formed in the right lower lobe; this discharged through the bronchus, and eventually became a medium-sized dry cavity, which, as it tended to contract, became surrounded by emphysematous lung.

The two main risks incurred by such a patient are both exemplified in this case. Hæmoptysis and sepsis are the two besetting dangers; the former has recurred for the last six years, the latter only after the patient's admission to hospital, where the cavity which was then containing blood must have become infected.

The hæmorrhage was sufficiently free to block the main bronchus to the right lower lobe, and thus caused some collapse of the lung and the physical signs already noted as present over the whole area of that lobe.

The entire absence of physical signs over the right lower lobe previous to the occurrence of the last hæmoptysis is one of the most interesting features of the case, and it brings to my mind a somewhat similar case published by S. West,—“a man of 44, who had been in good health and active work until fourteen days before admission to hospital” when, “after running some distance, he was seized with hæmoptysis, which since that time recurred on the slightest exertion.”

At the autopsy both the lungs were emphysematous, and in other respects healthy, except that in the left, in the upper part of the lower lobe, two small old cavities with fibroid walls were found, and in one of these a ruptured aneurysm the size of a cherry. “This case is important as showing how very limited the disease may be, and how difficult and perhaps impossible it may be to diagnose it.”

The value of the X-rays in obscure cases of hæmoptysis is obvious, and I believe it is important, as in this case, to obtain the X-ray picture during the attack of the hæmoptysis; the cavity containing the blood will then show up clearly on the screen, whereas the cavity might easily be missed if small and empty, and more especially if its walls are not dense and fibrous.

Not much can be done in the way of treatment. The patient should be warned against indulging in any sudden or undue physical strain; severe coughing should be especially avoided. The bowels must be kept freely opened with salines, and small doses of opium may be given; by these means the blood pressure can be kept under control. If the hæmorrhage is at all serious, amyl nitrite should be inhaled, and the blood thus drained away from the bleeding area. It is customary at present to administer calcium salts under these conditions, and this was done in my case. It appears to have been satisfactorily proved, however, by Addis, that the exhibition of large doses of calcium chloride has no effect on the coagulability of the blood, though he does admit that the calcium content of the blood can be influenced by such medication.

It is possible that in this patient the septic invasion of the cavity may prove to have been a

bleeding in disguise, and tend toward thrombosis of the vessel, from which the blood has been finding its way into the cavity. We can at least hope that such will be the case. Time will show whether such hopes are justified.

## THE NATURAL HISTORY OF THE COMMON FLEA, AND ITS CONNECTION WITH COMMUNI- CABLE DISEASES.

By G. MILLIAN, M.D.,

Physician to the Paris Hospitals.

ANIMAL parasites are becoming a more and more important factor in the ætiology of communicable diseases and their recognition as such gives them special and increasing interest to the physician. It therefore behoves medical men to become cognisant of their habits and we may commence with the flea, this frequent, nay oftentimes inseparable, companion of human beings, against which it is extremely difficult to protect ourselves. This parasite transfers its attentions from one person to the other with disconcerting agility, so that though we may be able to steer clear of the louse we fall an easy prey to the flea. I propose, therefore, to discuss its habits and mode of life so that you may be the better able to cope with it.

The biology of the flea has been exhaustively investigated by Drs. Bannerman and Kapadia, and their results are published in the fourth volume of the Plague Commission Report. According to these observers the flea, an apterous or jumping insect, with the body flattened transversely. It undergoes several complete metamorphoses, that is to say, it lays eggs which give issue to a larva, this larva surrounds itself with a cocoon whence by and by the fully-developed insect finds its way. This is a fact not generally known.

It lays its eggs at all times of the year, varying in number from one to five, spherical or ovoid in shape, of a pearly-grey colour. These are deposited, not, as with lice, on the body or garments of the host but in the interstices of the floor or carpet.

The egg gives issue to a worm-like larva provided with organs of mastication. It feeds on vegetable or animal detritus and inhabits sand or dust. The larva is quite small, whitish in colour, and not easily to be distinguished from the various other larvæ that are met with in the floors of dwellings.

In about a week the larva reaches its full size. It then becomes lazy, ceases to eat, and weaves for itself a cocoon of fine white silk.

The fully-developed insect comes out of the cocoon in from seven to fourteen days, having accomplished its evolution in about three weeks.

The young flea can do without food for a week or two so that it lies in wait for a favourable opportunity of obtaining a supply of blood.

The average duration of the life of a flea is—on the rat 41 days, on the guinea pig 20 days and on man 27 days.

Much moisture is inimical to the development of the flea and the same may be said of the other extreme of dryness.

Fleas reproduce their species all the year round but with less zeal in the month of June. A temperature above 90 deg. F., hinders flea reproduction and delays the development of the larva.

There are many varieties of flea: *pulex irritans*, the human flea; *pulex canis* and *pulex felis* appertaining to the dog and cat respectively. *Typhlopsylla musculi* is the ordinary rat flea, but this animal harbours many other kinds as well.

Although theoretically each species lives on its particular animal, which is considered to be its normal host, we find in practice that the same species may, according to circumstances, frequent many different animals.

*Pulex irritans*, for instance, which is almost exclusively met with in man, does not disdain the guinea pig and the rat; *pulex felis* prefers the dog or the cat to man; *pulex cheopis* affects the guinea pig almost as much as the rat, its normal host.

It will not attack man if there be a rat in the neighbourhood, but although it prefers the rat it eagerly turns to man or any other animal if short of food.

The fact that certain human and animal fleas may, under certain circumstances, inhabit the rat, justified the assumption that *vice versa* they may pass from the rat to man. This at any rate is the case with the Kirgus (nomad tribes in Siberia which are very subject to plague). They live crowded together in filthy, miserable huts, the soil of which teems with human, and especially dog fleas.

These biological data are of the greatest interest from a medical point of view more particularly in regard to the dissemination of plague. Verbitski demonstrated that fleas captured on rats dead or dying of plague contained the plague microbe in a virulent state. The same is the case with respect to human and animal fleas that have fed on a moribund plague patient.

The excreta of infected fleas also contain the microbe. It may be recognised either directly under the microscope or by cultivation on agar. Inoculation of these dejecta in the rat gives the plague just as does the inoculation of the cultures. The flea retains the virulent microbe in its intestine for five days when fed on healthy animals. It suffers no inconvenience from the presence of the bacillus although flies similarly infected die. It can live for a long time on a plague-stricken person.

The plague bacillus evidently multiplies in the flea's intestine since the number goes on increasing up to the fifth day.

When the plague-stricken rat dies the fleas quit the body, and it is then that they are most dangerous. This has been shown by actual experiment. If a rat dying of plague be placed in a cage along with a healthy rat, the two being separated by a partial wire gauze screen, as soon as the sick rat dies the fleas are seen to make their way on to the healthy rat which promptly develops the disease.

The flea can only transmit the virus during the first two or three days after its own infection by the plague-sick rat.

Verbitski has shown by numerous experiments that it takes at least five infected fleas to give plague to a healthy animal.

It remained to ascertain how the flea gets rid of the plague bacillus in view of the fact that after a few days a flea that has ingested plague bacilli if brought into contact with a healthy animal, does not impart the disease since it no longer contains the bacillus. This point has been cleared up by Bannerman and Kapadia.

The disappearance of the bacillus from the flea is hastened by a high temperature for it can no longer be detected in the dejections after a week when the fleas are kept at a temperature above 90 deg. F., whereas it is still present at the end of three weeks at a temperature of 77-80 deg. F. In all probability the disappearance of the bacillus from the flea is due to a process of phagocytosis by leucocytes, introduced in the fresh blood, for the

bacillus multiplies more freely if it fasts after sucking infected blood than when subsequently fed on healthy blood.

## QUACKS FALSE REMEDIES AND THE PUBLIC HEALTH.

By DAVID WALSH, M.D.Ed.,

Senior Physician, Western Skin Hospital; Physician, Kensington and Fulham General Hospitals.

### No. I.

RACE deterioration is one of the great problems that face the British statesman of to-day. It is the outcome of many influences that steadily sap the mental, moral, and bodily sanity of the nation. The present purpose is to discuss the matter from a single point of view, namely, the influence of secret remedies upon the health of the community, with an inquiry into the state of the present law as regards this particular trade, and suggestions as to future control of secret remedies in the interests of the public.

#### THE EXISTENCE OF THE EVIL.

In the following pages there will be no formal attempt to define the existence and extent of the damage resulting from the use of patent and proprietary medicines. The evil is notorious and has been exposed for generations past in the medical journals and elsewhere. Our mediæval forefathers were alive to the injury inflicted by it upon the public weal. In the reign of Henry VIII. scientific medicine received its first formal recognition in the shape of a charter to the Royal College of Physicians of London. That body, in return for the many privileges conferred upon it, was entrusted with absolute control of false medicines and false practice, with summary powers in London and seven miles round, which have never been repealed, for the committal to prison of offenders (in modern verbiage, "quacks" and nostrum vendors), and to seize and destroy their wares. The College has failed in its duty, but the powers remain and can be readily revived by Parliament. This point will be referred to later under "recommendations," and elsewhere.

The trade which was thus vigorously legislated against in the time of Henry VIII. has grown to an enormous size in the present day. Huge fortunes are amassed at the expense of the community by the sale of so-called remedies which are some of them inert, some of them potent, some deadly, but most of them fraudulent, inasmuch as they profess not only to cure a host of symptomatic maladies that could not possibly be thus affected by a single remedy, but also to cure the incurable. To take an instance, a nostrum is advertised to "cure" locomotor ataxy, a disease due to certain structural changes in the spinal cord. No cure for this complaint is known to medical science, and any such remedy is barely conceivable in our present state of medical knowledge. Were such a nostrum capable of curing locomotor ataxy it would be hailed with instant acclamation by the medical profession, however doubtfully they might regard it at first. Or turn to the ointment advertised to cure cancer and all surgical diseases, and shown by the British Medical analysis to consist of coloured lard! (a) Accordingly, when either vendor advertises his nostrum as being able to cure the complaint in question he is stating what is not true, and the money that he obtains for his nostrum is obtained from the public under false pretences. Now, the State has, since the earliest times, regarded that particular offence as punishable, so that under an active police system the vendor should come within the purview of the law on that score alone. But the State has further decreed since the days of Henry VIII. that the community should be protected against such false medical practice and false drugs. That position has been ratified by Parliament again and again up to the present day, but nevertheless the traders in such nostrums are able to carry on business in remedies of a transparently false, lying and injurious nature on a scale that is simply stupendous. This is owing to the laxity of the State, of the police, of the

Home Secretary, and of the General Medical Council; to the loose wording of Acts of Parliament; and to the neglect of their statutory duties by the Royal College of Physicians of London. Last, but not least, comes the agency of the newspapers and journals that share in the profits of this nefarious traffic, and hence are accessories in the offence of obtaining money under false pretences. As already stated, it is not intended to enter into a detailed examination of the extent of the evil, but illustrations will be found scattered through the following pages. Meanwhile, anyone who scans the reports of inquests, or who asks any observant medical man in a poor district for his views, or who consults the medical journals, will find no lack of evidence, grim, tragic, and ghastly as to the evils wrought by the greed of capitalist nostrum vendors upon the credulous victim who buys these worthless and often deadly wares.

Germany, which appears to have made up its mind to scotch the evil, has taken the logical step of correct definition. (a) The Australian Royal Commission Report (see below) says:—

"1,334. Definition of the term 'Secret Remedies.'

"The High Courts of Judicature of the Several States of the German Confederation have defined in extraordinarily numerous decisions the term 'Geheimmittel' ('Secret Remedies'). The most far-reaching definition out of these various judgments runs as follows:—

"A secret remedy is a medicament in the (a) shape of medicine to be introduced into the body of (b) man or beast, and intended for the (c) prevention, amelioration, or removal of (d) diseases, bodily injuries, or maladies of any kind whose (e) nature, preparation, and composition are not at the (f) latest made known at the time of the advertisement (g), completely to the ordinary understanding (f), qualitatively and quantitatively."

"These seven concepts (a, b, c, d, e, f, g) are thus characterised in detail and at great length by numerous distinct decisions cited from the Superior Courts of Justice in the States, everything showing a determination to construct an impregnable position of public defence."

The Germans, it may be noted, are solicitous that men as well as beasts should be protected from the evil consequences arising from the sale of secret drugs. In the United Kingdom the solicitude appears to be on the side of the cattle. The British legislature have enacted that (Fertilisers and Feeding Stuffs Act, 1893) all packages over 56 lbs. weight must give to the purchaser a legal warranty stating the composition of the article (whether fertiliser or feeding stuff). Yet the same authority neglects to protect the King's subjects, young or old, from the secret sale of drugs that, in the opinion of the medical profession, as expressed in their special journals, not to mention various competent lay authorities, are in most cases worthless, deadly, and more or less fraudulent.

The term "secret remedy" includes any drug or mixture of drugs of which the nature is kept secret by the proprietor, but which is sold to the public for the cure of one or more maladies. This definition covers all proprietary medicines the nature of which is not published. In this way certain proprietary medicines, such as chlorodyne, aspirin, eucaine, and other valuable remedies, recognised and largely used by the medical profession, are included. In the case of such remedies in the hands of respectable firms there would probably be little hardship in asking them to attach the formula of composition to their wares. In the medical world there is a sale for specially pure preparations of quite ordinary drugs, such as oxide of zinc, preparations of bismuth or opium, and charcoal. They are advertised as drugs pure and simple, and do not claim to be potent cures for this or that malady, and there is no apparent reason why the proprietor of recognised proprietary remedies should object to a similar amount of publicity. If the known simple drug finds a remunerative sale, why not the proprietary drug or mixture of drugs which reveals its composition? As a

(a) Report of the Royal Commission on Secret Drugs, Cures, and Foods to the Commonwealth of Australia. Vol. 1. 1907. p. 385.

(a) "Secret Remedies," p. 180.

matter of fact, in the case of aspirin and many most valuable drugs, the chemical composition is published in trade circulars and medical books, and often on the labels of the containing packages.

The best evidence yet collected, however, is Volume I. of the Report of the Royal Commission on Secret Drugs, Cures, and Foods, presented to the Parliament of the Commonwealth of Australia. The able and energetic Commissioner, Mr. Octavius Charles Beale, has collected an invaluable mass of facts regarding the trade in secret remedies, its effects, and its relation to legislation, with recommendations as to its control. This Report is likely to remain for some time the classical work of reference on the subject with which it deals. No candid person could even glance casually through its pages and fail to be convinced of the reality and the gravity of the evils attached to the secret medicine traffic in Australia. Quackery, however, is cosmopolitan and universal, and the Report shows that Australia is flooded with quack remedies sent from the United Kingdom, from America, and from other countries. The composition of these world-wide nostrums, their extravagant and fraudulent claims, their grossly extortionate cost, their catchpenny advertisements, are one and the same whatever the country in which they are sold. The steel and pennyroyal pills, sent out from a Midland town of England, are sold to credulous women at a high price in Melbourne and all over the world, for suggested purposes that it is impossible they could fulfil. Worse still, other pills, containing most deadly drugs (as shown by analysis) are sold in a similar fashion without anything on the wrapper to intimate that a dangerous drug is contained therein. Not all the British colonies, however, are foolish enough to permit their citizens to be deprived of their health and robbed of their money for the behoof of the patent medicine trader.

On November 28th, 1907, on the recommendation of Dr. Langley Browne, seconded by Dr. McManus, the General Medical Council resolved "that a committee be appointed to ascertain what legal precedents exist in the Colonies and Dependencies of the Empire and in foreign countries for the prevention of medical practice by other than legally qualified persons, and to consider what steps should be taken to procure effective legislation for the same purpose in the United Kingdom of Great Britain and Ireland." This view of the Committee as to the advisability of a Royal Commission were adopted by the Council and presented to the Lord President, Privy Council.

Any legislative action which controls irregular medical practice must surely control vendors of secret remedies who profess to cure disease thereby. These medically ignorant and unqualified persons treat cases without examination, sometimes by correspondence and by answers to printed questions. Neither the vendor nor the purchaser of secret remedies troubles his head about diagnosis, which, needless to say, can be determined only after personal examination by a skilled medical man. The pith of the matter is that the unqualified vendor is paid for the wares which he sells for the avowed purpose of curing human maladies. That being so, the investigation of secret remedies must necessarily become a part of the labours of any Royal Commission appointed to inquire into the conditions of medical practice by unqualified persons. If these views be accepted the recent action of the General Medical Council becomes of real importance in relation to secret remedies.

The report of the Unqualified Practice Prevention Committee of the General Medical Council (a) shows that:

Seventy-five British Colonies and Dependencies and foreign countries forbid the practice of medicine by unqualified persons, under penalty of fine and imprisonment, or both. It is not a little curious that unqualified practice should be sternly repressed in many Colonies and Dependencies, to mention a few, in New Brunswick, Ceylon, Mauritius, Western Australia, Cape Colony, while it is uncontrolled at home. It is controlled by the State in Austria, France, Belgium, Italy,

Greece, Switzerland, and many other countries, including some which are usually regarded as having dropped more or less behind in the world's progress, such as Spain, Portugal, Turkey, Chili, Panama, Montenegro, Nicaragua, and other Central American States. In the small island of San Domingo there is a penalty for practicing without registration, though otherwise qualified, a fact that offers a standing reproach to the British Empire, which has not adopted the obvious precaution of compulsory registration of medical men. In the desert Falkland Islands anyone wrongfully using a medical title is subject to fine and imprisonment. That is to say, a charlatan like Bridgwater, whose case will be referred to later in detail, is allowed to call himself M.D., U.S.A. (a title that does not exist) and to practise unrestrainedly in various parts of Great Britain; whereas he would have found short shrift in the small and remote Falkland Islands. The Report, in dealing with Great Britain and the existing legal provisions for the prevention of unqualified practice, fails to mention the unrepealed powers of the Royal College of Physicians of London over quacks and quackery in the metropolis, conferred by charter of Henry VIII. and confirmed by subsequent Acts up to the Medical Act of 1858, and the Medical Amendment Act of 1860.

Another valuable mine of facts is to be found in the little volume, "Secret Remedies: What they Cost and What they Contain," published by the British Medical Association. It reproduces a series of articles based upon the analysis of a long list of proprietary articles, and appends to each an estimate of bare cost—that is to say, of the remedies apart from package, wrapper, labels, and so on. The disproportionate profits thus disclosed may be illustrated by a few examples taken at random. Thus the first one given is that of a catarrh cure, sold at a shilling, against an estimated cost of one-thirtieth of a farthing. Of a cure for consumption sold by an American company, with a London agency, at a price of £2 10s. for a month's treatment, it is stated that the approximate cost of the two bottles that are supplied amounts together to 2½d. A notorious blood mixture, sold at 2s. 9d. a bottle, contained ingredients valued at 1½d. A rheumatic cure consisted of 50 tablets, costing 8d., and sold at 4s. 6d., and of 40 pills valued at ½d., and sold at 1s. 1½d. An enormously advertised ointment, the claims of which have been scathingly condemned by a British judge, sold at 1s. 1½d. a box, the contents of which are valued at ½d. An internal preparation for making the hair grow, sold at 2s. 6d., was found on analysis to contain ingredients valued at 1d.

The question of the prime cost of the merchandise, however, and of the profits accruing therefrom, is quite a minor matter. The cost of the raw material not infrequently bears a small proportion to the ultimate selling price when a finished article has gone through the various stages of production and distribution. The objections to the trade in secret remedies are based on other and more serious issues, as, for instance, the non-recognition of disease by the drug taker, especially in the earliest stages of cancer, consumption, and infectious diseases. What is easier for an uneducated person than to take some pain-killer to relieve the pain of an unrecognised cancer, instead of going to a medical man, who would recognise the disease at once and send the patient to a surgeon? Indigestion is often an early symptom of consumption, and many a consumptive patient has thrown away all chance of recovery by taking some of the much advertised and worthless cures for dyspepsia. Ulcer of the stomach, cancer of liver, stomach and bowel, appendicitis, and other serious internal complaints give rise to abdominal pain and discomfort, and are in nine cases out of ten ascribed by sufferers to "indigestion."

The facts furnished by the British Medical Association are of extreme value, inasmuch as they furnish evidence founded on the findings of analytical chemistry that cannot be disputed. They supply a basis, therefore, for testing the claims of the remedies thus analysed by the unfailing light of chemical science. In that way alone it is in many cases possible to show that the vendor is selling his wares on the strength of impossible claims. For

(a) Minutes of the General Medical Council. Vol. XLV. 1908. P. 429.

example, Warner's Safe Cure is sold "for kidney and liver and Bright's disease and jaundice" (label). It was found to contain (a):—

Potassium nitrate, 50 gr.  
Oil of gaultheria,  $\frac{1}{2}$  minim.  
Rectified spirit, 5 fluid drachms.  
Liq. ext. of taraxacum, 10 fluid drachms.  
Glycerine, 4 fluid drachms.  
Water, 8 fluid ounces.

From a medical point of view it may be asserted that the above mixture could not by any possibility cure Bright's disease, while the 10 per cent. of alcohol (approximately) contained therein would be absolutely injurious. Any person affected with chronic kidney disease who bought that medicine would therefore be purchasing not only a worthless but an injurious remedy. The Australian Royal Commission (\$685) (b) gives the following formula for the same nostrum:—"Warner's Safe Kidney and Liver Cure (on sale in Australia).—In Germany each maker of patent medicines must furnish the Government with the formula for the patent he makes. This is the one furnished by Warner for 'Safe Kidney and Liver Cure.' Each bottle contains:—Ext. lycopodium virginicum, 308 gr.; ext. hepatica (herb), 322 gr.; ext. gaultheria,  $7\frac{1}{2}$  gr.; potassium nitrate, 39 gr.; alcohol, 90 per cent.,  $2\frac{1}{2}$  oz.; glycerin, 10 dr.; water sufficient to make one pint.—*Formulary Druggists' Magazine*."

From this it is evident that there is not necessarily any fixed composition in a secret remedy. Clearly it can be varied from time to time in order to suit the pocket, the whim, or the convenience of the proprietor. A suggestive statement in connection with the alcohol admittedly contained in Warner's Safe Cure is that published in the Commonwealth Report (\$888), which says:—"Warner's Safe Cure, together with all the Warner remedies, is based, managed, and controlled by the New York and Kentucky Distilling Company, manufacturers of standard whiskeys which do not pretend to remedy anything but thirst."

The Australian Report gives an illustration of "some familiar Proprietary Drugs, and how they are regarded in Germany." These are taken from an official collection of the public warnings at the Local Health Office, 1905, under the title "Against Quackery and the Secret Remedy Swindle." Warner's Safe Cure is dealt with in the following sledge-hammer style (c):—

#### "WARNER'S SAFE CURE.

"102. By the circulation of a blatant prospectus, which is thrown into railway carriages for the travelling public, a certain firm—H. H. Warner and Co., in Frankfort-on-Main—advertises an alleged wonder-working remedy with the name of 'Warner's Safe Cure.' This is vaunted as a sure remedy for all diseases of the kidneys, liver, and urinary organs, jaundice, biliary fever, weakness, inability, heart disease, melancholia, malaria, backache, gout, rheumatism, convulsions, gravel, dropsy, Bright's disease, uterine disease, and the change of life. It consists of an infusion of liverwort leaves, aromatised with wintergreen oil, and contains nitre, glycerine, and alcohol in slight concentration, and relatively small quantities. Simultaneously with this remedy some sugar-coated aloes pills are to be used.

"These remedies have not the beneficial effects ascribed to them in the pamphlet, which is provided with several illustrations, and we must point out that there is not a single remedy for the ailments collected in the list, where they, moreover, bear absurd titles.

"Warner's Safe Cure is prepared by two representatives of the business of Warner and Co. in Rochester, namely, William R. Kennart and Anton C. Wehmar, in Frankfort-on-Main, and is pushed, in the drug stores and privately, in an elegant packing, which, in a characteristic way, shows repeatedly a safe as trademark. The price is far above the actual value. We warn you against buying this useless medicine."

When will British officialism denounce these and kindred remedies in similar fearless fashion?

From the variability of composition of secret medi-

cines it follows that any given analysis, although true of the particular sample upon which it was conducted, may not apply with exactitude to a further sample. After an exposure in public it is easy enough for a proprietor to alter his formula, so that he is enabled, when confronted with a published analysis in court, to deny on oath its accuracy as applied to the particular remedy he is selling at the time.

Among other works that should be consulted are Dr. S. Squire Sprigge's "Medicine and the Public," which has an excellent chapter (VI.) on "The Evils of Quackery," from which the following passage is quoted (a):—

"The licence enjoyed by irregular practitioners of medicine—by persons, that is, who possess in the legal sense of the word no licence whatever to practice—is absolutely wonderful. It would be ludicrous if it were not sad; medical electricians, medical hypnotists, medical botanists, and medical masseurs, on the one hand, and the votaries of 'safe' medicine, bone-setters, and the proprietors of patent remedies on the other—all are ready to treat the community for every sort of pathological condition, and all claim to be the depositaries of therapeutic secrets which have been denied to the intelligence of men who have made medicine and surgery the study of their lives, and who have stood the test of examination of their knowledge. Surely but very little thought bestowed upon this situation should enable the dullest to see that it is a highly ridiculous one, and one that reflects in no creditable manner upon public astuteness and good sense. Yet the ignorant and the product of the highest culture will alike seek the administrations of the quack, and of the two the latter appears sometimes to fall the easier victim."

Another useful book of reference is "Patent Foods and Patent Medicines," by Dr. Robert Hutchison. The "Australian Report" quotes largely from the work of Dr. William Murrell, Physician and Lecturer to the Westminster Hospital, who was one of the first to investigate the composition of patent medicines, and has given a long list of supposed active ingredients of popular "patent medicines," which will be found in his well-known book, "What to do in cases of poisoning."

(b) The presence of such a list in a practical guide to the treatment of poisoning cases needs no further comment.

Some valuable information is also to be found in a (c) report upon Patent Medicines and Headache Powders furnished by Mr. Thomas Macfarlane, Chief Analyst of the Laboratory of the Inland Revenue Department, Ottawa, Canada, to the head of that Department.

#### SECRET DRUGS.

No age and no class of disease are uncatered for by the quack and the quack medicine vendor. Perhaps the readiest plan of furnishing readers with a general idea of the nature and extent of a few of their trade will be to give an outline sketch of their wares under various headings, together with a running comment and any other details that may be necessary for the sake of clearness. As so much good work has been already done in this direction, this part of the subject will be dealt with in a brief and condensed manner.

#### CHILDREN'S "SOOTHING" MEDICINES.

The practice of dosing children with teething, soothing, and cooling powders or syrups, baby's friend, and so on, is extremely common. The main drugs contained in preparations of this kind are opium and its derivatives, and calomel, both of them deadly drugs when given to infants. Thus death has been known to follow the administration of one drop of laudanum to a child 7 days old (Taylor). Some of the soothing medicines sold for children contain morphia, which is obviously more dangerous than laudanum. Other dangerous drugs, such as acetanilide, sometimes enter into these patent medicines for infants. No medical man would dream of giving acetanilide to children, nor would he give opium or its preparations except upon

healed spontaneously. No decided conclusion could be drawn as to the character and further course of the affection from the quantity of tuberculin required to set up a manifest reaction when tuberculous disease was present at the time of inoculation. When the tuberculin was given subcutaneously a dose of 3 mg. was frequently necessary to set up evidence of a latent tuberculous disease.

The same paper contains an account of  
**THE TREATMENT OF TUBERCULOUS GROWTHS AND  
ULCERS OF THE NASAL SEPTUM,**

by Dr. Beese, Rostock. These affections are, he says, mostly localised in the cartilaginous part of the septum. They are frequently the only spot in the body in which tuberculous disease is present, and especially when the infection is brought about by picking the nose. The former usual and almost exclusive treatment of the disease by scraping and caustics is frequently ineffective, as experience shows that relapses are frequent after this anything but radical form of treatment.

It is much more proper to excise the whole of the diseased portion of the septum. Even then perforation of the septum often takes place in the end. Examination of the excised portion has shown why scraping and caustics are generally ineffectual; one frequently finds the cartilage already recrossed, and the tuberculous affection already pushed forward through to the other side, even when this is to all appearance sound.

Excision is easy to carry out. After the part has been anaesthetised and made bloodless, it is cut through with a narrow-bladed knife. A fine, blunt-pointed knife is then passed through the opening, and the diseased part excised under guidance of the eye. The principal point is not to fail to cut well round, so as not to leave any portion that is diseased behind. The hæmorrhage is only slight, so that tamponade is not necessary. Permanent recovery has followed this line of treatment in the Rostock Klinik in a short time, a fact that is so much the more important in that patients are at the same time freed from the whole of their tuberculosis.

### AUSTRIA.

#### HYPOPHYSIS CEREBRI.

At the Congress, Hochwart raised an interesting discussion in the Section of Neuropathology, on the diagnosis of disease in the hypophysis cerebri. In the first place, he found that acromegalia was not a constant associate with this disease, as he had observed in literature 155 necropsies where the hypophysis was diseased, but no acromegalia was present. His own cases bore out his contention that some difference existed in the nature of the disease present that should be diagnosed. These cases, he affirmed, had not the general psychical disturbance and tendency to sleep, but usually had the hæmianoptic defect, ocular paralysis, temperature anomaly, etc., while radiology confirms the enlargement of the sella turcica. The individual is usually small in person, if not dwarfish. Frequently impotence with consequent amenorrhæa is the result, though in the young there may be found a stunted genital development with a large amount of obesity in the part which assumes the form—degeneratio adiposo-genitals, coined by Fröhlich. The enlargement of the gland assumes every variety of form, but the most common is a compression of the chiasma, as well as the posterior part of the brain.

The duration of this disease varies from a few months to three years. The differential diagnosis is complicated with other diseases at the base of the brain, such as syphilis, tubercle, etc.

#### SCROFULA OR TUBERCLE.

In the section for Pediatrics, Prof. Escherich gave a long history of cause and effect in scrofula and tuberculosis, which might be summed up under a few headings, as follows:—The cause of tuberculosis in children depends very much upon the nature and virulence of the infection, site of entrance, and distribution in the body, as well as the age and constitution of the individual. The scrofulous subject presents a stubborn recurrent catarrh of the skin and mucous

membrane leaving the so-called scrofuloid in the juvenile form, which usually occurs between the first and fourth year. The scrofulous condition commonly arises in a lymphatic constitution. The subject may appear well nourished and over-developed, with fat, associated with a pasty condition of the skin, inclining to be eczematous, with indolent lymphatic swellings and hyperplasia of the lymph apparatus, as well as enlargement of the spleen and thyroid gland. This characteristic constitutional anomaly is the assumed cause, but how to explain the lymphatic constitution and extension is not to be easily demonstrated. One thing we do know—that it is often associated with other diseases, such as rachitis, etc., and that the highly sensitiveness of the integument to the tuberculin toxin convinces us that it is closely allied to that disease. Another proof is that these subjects may be immunised with increased doses of the old tuberculin, rising to 1 ctm. of the A.Y.O. toxin, which speedily reduces this hyper-sensitive condition; at the same time a rapid improvement takes place in the cutaneous surface and catarrh of the mucous membrane, while the bacilli in the glands and the osseous centres are finally affected. The treatment has always been rationally conducted in scrofula with iodide and cod-liver oil, but the recent immunising with the old tuberculin is an adjunct which has added largely to our curative agents in scrofula. Barbier said that tuberculosis in children was one of the greatest scourges we had to fight against. According to statistics, tubercular victims range from 30 to 60 deaths during every first year of 200 children born.

### FROM OUR SPECIAL CORRESPONDENTS AT HOME.

#### GLASGOW.

THE topics chiefly agitating the medical mind are the proposed

UNIVERSITY CHAIRS AT THE ROYAL INFIRMARY, AND  
THE SCHOOL BOARD'S SCHEME FOR THE MEDICAL  
INSPECTION OF SCHOOL CHILDREN.

As regards the latter, the board have passed over the claims of local practitioners, and have appointed a gentleman presently resident in England as chief medical inspector. The new inspector is a graduate of Edinburgh University. Whether this passing over of local men has been due to the, as some think, undignified attitude of the profession in reference to the subsidiary appointments, and their complaints as to the scale of pay for these, no one can say. The subsidiary posts will necessarily be filled by local men, and terms will have to be arranged. A jump from £560 for chief inspector to £40 for part-time assistants is, however, rather a record leap for School Board financiers. Govan School Board have appointed as their chief inspector a local—that is to say, a Glasgow—man.

Under the will of the late Dr. Henry Muirhead, who died some fifteen years ago, a scheme of medical education for women was to be established, which his trustees have never been able to carry out. For years their sole task has been to accumulate interest with principal. Hence they are now joining with St. Mungo's College in endeavouring to arrange with Glasgow University and the Carnegie Trust for the establishment of certain University chairs at the Royal Infirmary to take the place altogether of the present St. Mungo's College. The chairs are to be of four subjects—(1) Medicine, (2) Surgery, (3) Midwifery, and (4) Pathology. The endowment of two of these chairs with an income of £400 each from the Muirhead trust funds will absorb part of the revenue of these funds. Parliamentary powers to do this are to be sought.

It is hoped that by means of these chairs the dwindling classes of St. Mungo's College will be replaced by four well-attended University classes, the students of which will relieve the Western Infirmary from overcrowding, and benefit the Royal by their attendance.

**BELFAST.**

**QUEEN'S COLLEGE, BELFAST.**—PRESIDENT'S ANNUAL REPORT.—This report, which has just appeared, is of special interest at the present moment, when the College enters on its University career. Naturally the changes which are taking place are noted in the report, which thus deals with the future as well as with the past. The College was only endowed to the extent of £7,000 per annum: it will now, as the Queen's University of Belfast, enjoy an income of £28,000 per annum, to which private endowments will be added. Owing to this increased endowment it has already been arranged to add considerably to the teaching staff, and the prizes and scholarships will be increased in number and value by the amount of about £1,000 per annum. In addition to the increased annual endowment, the Treasury has granted a sum of £60,000 for providing necessary buildings, land, and equipment. Part of this will be spent at once in providing extra class-rooms, rooms for the lady students, professors' common-room, etc., and part will be held in reserve to meet any needs that may arise in the next few years, when the University is well started on its career.

Several new Chairs have been established in the Arts and Science Faculties, and in the Faculty of Medicine, though no new chairs are established, a number of appointments have been made. Professor Milroy is the first occupant of the new post of Dean of the Faculty of Medicine, and Demonstrators and Assistants have been appointed in all the more important subjects.

During the Session 1908-9 there were 456 students attending the College, of whom 224 were in the Medical Faculty. Of the 456 students no less than 410 came from the Province of Ulster, 4 from Munster, 12 from Leinster, and 5 from Connaught, while England supplied 11, Scotland 5, and the Colonies most of the remainder.

**LETTERS TO THE EDITOR.**

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

**THE PSYCHIC TREATMENT OF INTEMPERANCE.**

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—I have read with much interest your report (September 15th) of Dr. Quackenbos's address on the treatment of intemperance, and the comments thereon in the current issue.

"Medical Temperance Reformer" expresses regret that Dr. Quackenbos does not fully describe his method. This omission is probably due to the lecturer taking it for granted that his hearers were acquainted with the ordinary methods of inducing hypnosis. They are fully described in the text-books (a), and can be easily learnt by medical men.

I have been using hypnotic suggestion in the treatment of chronic alcoholism, drug habits, and abnormal nervous conditions for over twenty years, and some hundreds of such patients have passed through my hands. At first, fired by the enthusiasm of my venerated teacher, the late Dr. Liébeault, of Nancy, I expected to cure every drunkard who was brought to me. Experience, alas! has taught me otherwise, but I have had some surprising and brilliant successes, and have never seen any harmful results. I have rarely or never seen other systems succeed where hypnotism, properly applied, has failed. Alcoholics are eminently "suggestible," and the advertised methods of cure—Keely's, Oppenheimer's, etc., work largely on that principle.

To be successful one has to treat both the moral and physical causes underlying the condition, and hypnotism enables us to act on the latter, as well as the former, by suggestion.

In carrying out a system it is desirable to have a

(a) Vide books by Milne Bramwell, Albert Mole, Lloyd Tuckey, Bernheim, etc.

working hypothesis to explain it, and the theory of appealing to "the subconscious mind" of Myers or "the other fellow" within us of Wendell Holmes is the one adopted by Dr. Quackenbos and most hypnotists, it being presumed that this underlying self is better and wiser than the everyday personality.

I find my conclusions closely correspond with those of Professor Forel, the eminent psychologist and ardent temperance reformer of Zurich, who thinks hypnotic suggestion should be employed as an effective aid to cure in a very large proportion of alcoholic cases as a means of strengthening the patient's will, removing the craving, and developing his moral sense.

I am, Sir, yours truly,

CHAS. LLOYD TUCKEY, M.D.

London, W., September 24th, 1909.

**MEDICAL MEMBERS OF PARLIAMENT.**

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—In the course of your excellent article to-day, September 22nd, on the proposed Patent Medicine Committee, you express a regret "that it was left to a lay member of the House of Commons to call attention to the matter," and at the same time you declare your belief that when the call for action comes, medical members will not fail in their duty. The fact is that it would be difficult to name a single medical member who displays any sign that he holds his position in any respect as a representative of his profession. Nearly all the present medical members are politicians first, doctors afterwards. They are not to be blamed for this. It is, as a rule, impossible for an active medical practitioner of any rank to be a member of Parliament, impossible for him to give up from six to nine months of his year to public work. If the profession wishes to be represented in Parliament under present conditions it must subsidise selected men. It would no doubt be a great advantage if this could be done. The position of the profession in all its relations with the State and the public might be much improved if it had in the House even a single man endowed with the personal, intellectual and statesmanlike qualities that command attention in that assembly, and who would devote himself to the interests of his brethren. Such a man might easily destroy the prejudice which now affects the advocacy of professional interests by members of the profession. He could demonstrate the fact, which is so often dwelt upon in various places in the Medical Press—namely, that the profession seeks and asks nothing from Government which will not bring as great advantage to the people as to themselves. In the meantime, it is very fortunate that the quackery question has been taken up in earnest by an independent lay member, Captain Craig. He cannot, at any rate, be charged with selfish motives. The obligation under which he has placed the profession and the public by the initial steps he has made possible in one direction of medical law reform is already great. We need not doubt that the obligation will, in due course, be largely increased. As the addition of my name would add no weight to these remarks, I beg to be allowed to subscribe myself,

I am, Sir, yours truly,

MEDICAL POLITICIAN.

Birmingham, September 22nd, 1909.

**THE DECLINING BIRTH-RATE.**

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—Your correspondent, "A Yorkshire Practitioner," is quite right in his main statements. If the birth-rate throughout all the classes were controlled by prudence and directed by science, all would be well, but when due entirely to motives of narrow egoism, a falling birth-rate connotes moral decay and indicates the decline of the race. As I have over and over again pointed out, the question has been fully illustrated in the history of France during the past fifty years. She has lost, and can never regain, her dominant position in Europe, her numbers being now only half those of her mighty German neighbour. At present Germany has at home upwards of 68,000,000,

besides some millions who, although in foreign countries, have not severed their connection with the Fatherland, and she is increasing at the rate of nearly a million a year. France, on the other hand, remains stationary at 39,000,000, and has none abroad save a few thousands, mostly officials, in her vast oversea possessions. The birth-rate in Germany is falling, but, if it continue, it will take more than fifty years before she is in the same stationary position as France. The opinions of scientific Frenchmen are unanimous as to the significance of the facts. I quoted two—M. Bertillon and M. Leroy-Beaulieu—in my last. A minute examination of French social conventions, of French marriage customs, and of the moral qualities of the people, will convince the inquirer of the reality of the decadence of this gifted race, and, unfortunately, the British are now displaying the same symptoms. I cannot on this occasion occupy much more of your space, and I must not reiterate old statements; but I would point out to "A Yorkshire Practitioner" the danger of generalising from a single instance. No doubt it might have been better if his gardener's wife had brought forth a baby (he does not state how many there are) less frequently than every ten months; but it does not at all follow that she would be better without children, or without a fair-sized brood, and rickets is an easily preventable disease, and surely it might easily have been prevented in this case. He will find in all the manufacturing towns in his county vast numbers of mill hands who deliberately limit the number of their offspring, or have none at all, merely because children are no longer "pecuniary assets," being forbidden by the Factory Acts to work and earn wages. These mill-hands, man and wife, earn together two or three times the wages of "A Yorkshire Practitioner's" gardener, and yet rickets prevails to an enormous extent among their children. The mothers decline to suckle them; it prevents them from earning money, and the babies are bred up as rickety wasters, entirely from lack of proper food and feeding. In our own country, as in France, it is among the classes from above downwards, those best able to support and put out in the world the normal number of children, who are shirking the obligations of parenthood and ignoring their duties as citizens of the Empire. It is this unequivocal symptom of moral deterioration which is so disquieting; it is impossible for the most extreme optimist to ignore its sinister significance.

I am, Sir, yours truly,  
A STUDENT OF SOCIOLOGY.

September 24th, 1909.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—May I just point out to your correspondents that they are entirely on the wrong scent in attributing the declining birth-rate to selfishness or a craving for luxury and comfort?

The vast majority of this country nowadays, with unearned incomes, in trade or profession, live from hand to mouth. The competition for a livelihood during the last few decades has become greatly intensified, inasmuch that an indefinite number are, as a consequence, driven through actual necessity to limit their progeny. This explains the declining birth-rate, and not what your correspondents suppose.

I am, Sir, yours truly,  
CLEMENT H. SERS, M.R.C.S.

Brighton,

September 24th, 1909.

[Our correspondent, "A Yorkshire Practitioner," raised the question in our last issue that "the decline in the birth-rate is most manifest in countries where riches have increased," and as a fact this is so, as evidence of which we need only instance the United States, France, Germany, and England. In Australia, where, man per man, money is perhaps more evenly distributed than anywhere else, the decline in the birth-rate has become a scandal, being due entirely to selfish motives, and not to the need of economy. Mr. Sers' reply is scarcely in accordance with these facts, although in individual cases his theory is doubtless correct.—Ed.]

## OBITUARY.

HUBERT ELWYN J. BISS, M.A., M.D. Cantab.,  
M.R.C.S., L.R.C.P. Lond., D.P.H. Ed. and Glas.

WITH sincere regret we have to announce the death of Dr. Hubert Biss, at the early age of 37, after a painful illness. The son of a well-known London physician, Dr. C. Y. Biss, he was educated at Dulwich College, and afterwards at Cambridge, where he graduated B.A. in 1892 (2nd class Science Tripos); M.A. in 1896; M.B., B.C., 1896; M.D., 1901. He studied also at Middlesex Hospital and Neuchâtel, and took the M.R.C.S. Eng. and L.R.C.P. Lond. conjoint diploma in 1896; and the D.P.H. Edinburgh and Glasgow in 1899. After graduation he held various posts, among them being that of House Physician to the Brompton Consumption Hospital, and Assistant Demonstrator of Anatomy and Biology in the Cambridge University Laboratory. For some years he was Assistant Medical Officer at the Grove and the Park Fever Hospitals, under the Metropolitan Asylums Board, and it was there that some of his best professional work was undertaken. Dr. Biss acted as resident physician during the last illness of the late Mr. W. E. Gladstone, both at Bournemouth and at Hawarden Castle, and to him fell the melancholy duty of signing the death certificate of the great statesman. In 1903 Dr. Biss married and started practice at Eastbourne, whence he removed in 1906 to London. In the latter place he specialised in medico-legal work, especially as regards the Employers' Liability Act, and he became medical referee to several well-known insurance offices. During the few years that elapsed he was rapidly building up an extensive practice, when the symptoms of a gastric trouble, from which he had suffered for many years, took a serious turn, and he went to a nursing home at Eastbourne, in order to be under Dr. Harper. Hemorrhage set in from a duodenal ulcer, and he passed away on September 20th.

We write this notice with a deep sense of personal loss, as Dr. Biss had been for some years a valuable contributor to our columns, and on his coming to London in 1906 became Assistant Editor to THE MEDICAL PRESS AND CIRCULAR. His brilliant pen and his scholarly genius were ever at the service of the profession to which his life was devoted. His genial manner and sterling character secured him many friends, but by none will his loss be felt more deeply than by those who were brought into close contact with him in his journalistic work.

## SPECIAL ARTICLES.

### THE TYPHOID OUTBREAK AT CLONTARF.

IT will be remembered that in the autumn of last year a serious outbreak of typhoid fever, involving 142 patients, occurred at Clontarf. In the spring of this year the outbreak was the subject of a report by Sir Charles Cameron, Medical Superintendent Officer of Health of Dublin. This report we had occasion to comment on in our issue of 31st March last. We then found ourselves unable to agree in certain of Sir Charles Cameron's conclusions as to the causation of the outbreak, while, of course, accepting his statement of facts.

The outbreak, however, is now the subject of a report by Surgeon-Colonel Edgar Flinn, Medical Inspector for the Local Government Board (a), which presents many points of difference from that by Sir Charles Cameron. These points of difference occur not only in the statements of conclusions, but also in the relation of facts.

The two observers agree that the immediate cause of the outbreak was the infection of a dairy which supplied milk to a great many of the houses in Clontarf. There was no illness among any of the people employed at the dairy or in any of their

(a) "Annual Report of the Local Government Board for Ireland for the year ended March 31st, 1909."

families. The question for solution, therefore, was—How did the dairy become infected?

According to Surgeon-Colonel Flinn, there were five possible solutions of this question:—(1) Were any of the milking staff "typhoid carriers"? (2) Were the emanations from the refuse deposited at the Fairview sloblands responsible? (3) Were the germs of infection spread in the course of the main drainage operation? (4) Was defective drainage the medium of infection? (5) Was infection introduced from communication with infected households? Sir Charles Cameron inclined to adopt the first of these solutions as the correct one, mainly, it would appear, because "one" of the milkers was, after being examined by a bacteriologist, removed from the duty of milking. Surgeon-Colonel Flinn, on the other hand, adopts the fourth solution as most probably correct. He accepts as the cause of the epidemic an un-notified case of fever which occurred in St. Joseph's Square in the immediate vicinity of the infected dairy a few weeks before the first case of the outbreak was notified. Sir Charles Cameron stated as his positive opinion that "this case of fever, supposing it to have been typhoid fever, was not the cause of the epidemic." It is a matter of extreme difficulty to come to any opinion on the matter, the discrepancies between the accounts of the two reporters being both numerous and important. It is necessary to draw attention to some of these.

Sir Charles Cameron reports that *one* of the milkers, having been examined by a bacteriologist, was taken from the dairy work. Surgeon-Colonel Flinn reports that *three* were so taken, and transferred to other employment. It is possible that one of the men was a "typhoid carrier"; is it likely that there were three "typhoid carriers" together?

Sir Charles Cameron says (a):—"It is alleged that in the month of August, 1908, the sewer from St. Joseph's Square was opened, etc." Surgeon-Colonel Flinn fixes the date at a different time (p. 107):—"I have, however, ascertained that the work of laying the new sewer in the vicinity of the dairy premises was only commenced on the 15th September." Neither observer considers the opening of this sewer to be of importance, Surgeon Flinn regarding it as too close in date to the outbreak, Sir Charles Cameron as too far from it. As the work in question was being done for or by the Dublin Corporation, it ought to have been possible to fix the date.

Sir Charles Cameron states (p. 77) that "no cases occurred until late in September." Surgeon-Colonel Flinn mentions (p. 107) that "the earliest case in the series was first medically attended on the 15th September," and adds: "No doubt this case had been incubating the disease for a week or more. Thus the commencement of the outbreak must be dated from approximately the first week in September."

In the face of such contradictory statements as these it is difficult to come to a conclusion as to the real causes of the outbreak. We see no reason, however, to alter the opinion we expressed some months ago that the dairy was infected from the case in St. Joseph's Square. Whether the infection was carried by deficient drainage or by personal communication we cannot say. It seems to be the fact, however, that the drain was laid open by the Dublin Corporation in the immediate vicinity of the dairy at a time when infective material was present in it. This is so, whatever be the exact date at which the drain was opened.

Another fact which seems to have hampered both Sir Charles Cameron and Surgeon-Colonel Flinn was their failure to retain the general services of a bacteriologist to assist them in their investigations. It is true that early in the investigation Sir Charles Cameron submitted certain material to a bacteriologist for examination. At a later date, however, this gentleman's services were obtained by the proprietor of the dairy, and he made certain further investigations in the interests of the latter. Sir Charles Cameron appears to find it a grievance that the results of these investigations were not communicated to him (p. 57). The

same bacteriologist is Bacteriologist to the Local Government Board, but that body does not seem to have made any demand on his services during the investigation.

## REVIEWS OF BOOKS.

### THE BODY AT WORK. (a)

THE reason for the writing and publication of a treatise of this nature is not at once apparent to the average professional man—nay, even to the scientist and to those who dabble in smatterings of science the work can hardly commend itself as a necessity. This criticism does not in any sense intend to convey the impression that Dr. Hill's work is not of a high class—full of interesting and correct facts, for to one who is acquainted with physiology the book is interesting and replete with information as far as it goes. An author may generally be relied upon to state in the preface his object in producing such a work. Let us therefore examine the preface with the view of unearthing the author's reason for placing on the market a popular text-book on physiology which runs into close on 450 pages.

He considers that physiological text-books are plentiful, but doubts "whether the interests of the amateur of science have been adequately cared for."

He says that the physiologists who write for medical students assume that their readers have passed through two years of preliminary training in physics, chemistry, and biology, and can also have their studies supplemented by practical work in a laboratory; further, they treat all parts of the subject with equal thoroughness. "In this book," he says, "I have endeavoured to describe the phenomena of life and the principal conclusions which have been drawn as to their interdependence and as to their causes in language which will be understood by persons unacquainted with the sciences upon which physiology is based."

This last statement is, of course, the point at which we feel inclined to join issue with the author. For instance, to anyone unacquainted with chemistry, the information will scarcely be readily assimilated that the molecular formula for the blood of the horse is  $C_{712}H_{1130}N_{214}S_2FeO_{245}$ . Further, "the tendency of proteins to break up along these two lines—the fatty acid line and the aromatic acid line—is of considerable interest. The one line is represented by acetic acid  $CH_3COOH$ ; the other contains the hexone radicle,  $C_6H_5$ ." Such sentences as this must indeed give pause to the amateur scientist who is unfamiliar with chemistry.

As a final criticism on the purpose of this work, it occurs to one to suggest that the amateur scientist who has "scorned delights and lived laborious days" in order to make himself familiar with all the physiological information contained in this volume, will feel aggrieved that "such sections of the subject as are generally considered unsuitable for ordinary discussion" have been passed over. Surely the reader who incurs the labour of making his own the knowledge here set forth, including that on the brain and the organs of special sense, would consider himself badly treated to find that he is not to learn anything of the physiology of, say, reproduction.

Having said so much in the nature of querulous criticism, it is but just that the highest praise should be bestowed upon the work from the standpoint from which it has been written.

The book is got up in first-rate style, and the illustrations and printed matter are excellent. We wish the author as large a circle of readers as his industry and distinguished position as a physiologist merit.

THE resignation is announced from the London Cancer Hospital of Mr. N. W. Bourne, M.R.C.S., who has been connected with that institution in various capacities for the past thirty years.

(a) "The Body at Work: A Treatise on the Principles of Physiology." By Alex. Hill, M.A., M.D., F.R.C.S., sometime Master of Downing College, Cambridge. With 46 illustrations. London: Edwina Arnold, 1908.

(a) "Report on the State of Public Health in Dublin for the year 1908," p. 71.

## LITERARY NOTES.

VOLUME VI. of Sir Clifford Allbutt's "New System of Medicine" on "Diseases of the Heart and Blood-Vessels" is announced by Messrs. Macmillan to be ready shortly. Volumes VII. and VIII. on "Diseases of the Nervous System" are in active preparation, and will complete the work.

\*\*\*

MESSRS. LONGMANS, GREEN AND CO. announce a new edition of "Quain's Anatomy," which will appear in four volumes, edited by Professors Schäfer and Symington, and Dr. T. H. Bryce. Vol. I. is now ready, Vol. III., Part I., is also ready, and Part II. of the same volume is in the press.

\*\*\*

FROM Mr. H. K. Lewis we have the announcement of a re-issue of Dr. Frederick Roberts' "Theory and Practice of Medicine" (10th edition), with an appendix bringing it up to date. The merits of this manual are so well known and appreciated as to render further comment unnecessary. The same publisher has just issued a work on "Immunity and Specific Therapy," by Dr. D'Este Emery, Clinical Pathologist to King's College Hospital.

\*\*\*

DIABETES is not only a common disease in India, but has a large mortality in that country. In a booklet of forty pages, entitled "The Dietetic Treatment of Diabetes," by B. D. Basu, Major I.M.S. (Retired), The Panini Office, Allahabad, India, the author deals with dietary alone, and quotations from well-known authorities on this disease are freely interspersed throughout, which is intended for the general public as well as the medical practitioner.

\*\*\*

A NEW edition of Dr. Jellett's "Magnum Opus: A Manual of Midwifery," is announced in the "University Series" by Messrs. Bailliere, Tindall and Cox. Among the many works issued from the press of recent years, this manual has been a distinct success, and the new edition has been re-written and brought up to date, with new illustrations throughout the work. The same publishers have also put forth this week a new edition of Mr. Shillington Scales' "Practical Microscopy," and a new work on "Sanatorium Treatment," by Dr. Rufenacht Walters, one of the pioneers of the Open-Air Treatment of Disease.

\*\*\*

"AN Appeal on behalf of the Government and People of China," by H.E. T'ang K'ai Sun (Morgan and Scott, London, 3d.) is a pamphlet of 32 pages dealing with the opium question, on the wrongs and rights of which we have heard a good deal. The pamphlet, as a matter of fact, is the speech of His Excellency T'ang K'ai Sun, when submitting resolutions on behalf of the Chinese delegation at the International Conference on Opium in Shanghai. Of the debasing and degrading results of the opium habit in China there can be no doubt, and we welcome any measures that may set the Government and people of the Chinese Empire free from this terrible vice—scourge it may almost be called.

\*\*\*

THE Editor of the *Girl's Own Paper and Woman's Magazine*, in the number for October, offers the following very sensible advice to the readers of that excellent magazine:—"Is it not time our girls realised that it is no more menial for them to be doing what is legitimately woman's work—the care and beautifying of a home—than to be working under men employers in city offices, and in many cases doing the work of office boys? The pernicious habit of regarding household work as 'menial' is one of the unfortunate products of the present half-educated times. It has been a serious mistake to teach girls smatterings of every imaginable subject, excepting the one she most needs in her after-life—home-making and home-keeping."

THE important paper to be read on anaesthetics by Dr. Frederic Hewitt, on October 25th, will be before the Medical Society of London, and not at the Royal Society of Medicine, as inadvertently stated in our last issue.

## MEDICAL NEWS IN BRIEF.

### The Health of Belfast.

In his annual report to the Belfast Corporation, Dr. Bailie, Medical Superintendent Officer of Health, states:—The death-rate, which is 19.5 per 1,000 of the population, whilst still high, is the lowest ever recorded for the city, and is 0.7 below that of the 22 principal town districts of Ireland. The number of cases of zymotic diseases notified is also the lowest on record, and the death-rate is comparatively low. During the first quarter of the year the number of persons suffering from chest diseases was considerably above the average, those principally affected being infants and aged persons. The average annual death-rate for the quarter was also correspondingly high, being 11.3 per 1,000, whereas the rate recorded for the year was only 7.4 per 1,000. The population of the city is set down as 380,344, and the density of occupation 25.8 persons to an acre. The number of deaths registered as having been caused by phthisis (pulmonary tuberculosis) was 880, or 11.69 per cent. of the total deaths registered from all causes, which is equal to a rate of 2.3 per 1,000 of the population, or, in other words, 1 in every 432 of the population died from this disease during the year under review. In the year 1907 the number of deaths attributed to this cause was 926, being 1 in every 399 of the population. The average annual rate of mortality from tuberculosis during the 13 years 1893-1905 was 3.2 per 1,000, but has since steadily declined, the rate for the years 1906, 1907, and 1908 being 2.7, 2.5, and 2.3 per 1,000 respectively.

### Notification of Births—Confusion in Potteries Jurisdiction.

At the Stipendiary's Court at Burslem, on the 21st instant, Dr. William S. Allen, practising at Burslem and Tunstall, was charged under the Notification of Births Act, 1907, with failing to notify a birth to the Medical Officer of Health within thirty-six hours. For the defence it was admitted that the required notice had not been given, but it was through a misunderstanding. Dr. Allen took the Tunstall work, and his partner, Dr. Williams, the Burslem work. Dr. Williams had been in the habit of sending in the notices required by the Act as concerned Burslem, and so far as Dr. Allen was concerned the Act had not been adopted in Tunstall. The birth in question occurred in Pinnox Street, Tunstall, and the boundary of Burslem and Tunstall went through Pinnox Street. For all practical purposes Pinnox Street was in Tunstall, but it was partly under the jurisdiction of Burslem. Dr. Allen was not aware of the latter fact, or he would have given the usual notice. There was a second summons with regard to another birth in Pinnox Street, and the same defence was offered. The Stipendiary accepted the explanation offered, and merely made an order for the payment of costs in the two cases. Mrs. Eliza Shaw, nurse, was summoned for failing to notify a birth; and Mrs. Helen Porter, nurse, was charged with failing to notify two births. All three summonses were with respect to Pinnox Street and the immediate vicinity, and defendants urged that they thought they were in Tunstall, where no notification was required. Defendants were ordered to pay the costs in each case.

### Medical Sickness and Accident Society.

At the last monthly meeting of the Executive Committee of this Society it was stated that the business of the Society is still growing in a satisfactory manner. Every year shows an increase in the number of members and the amount of the invested reserves, while the amount paid away in sickness claims does not exceed what is expected and provided for in the tables of contributions. The Society has no agents and pays no commission, while the funds earn considerably more interest than is assumed in the valuation of the business. The substantial surplus thus produced allows of the payment of a handsome bonus to those members who reach the age of 65.

**Sudden Death of a Medical Man.**

MR. WALTER SCHRÖDER held an inquest at Marylebone, on the 23rd instant, on the body of Eustace Rhodes St. Clair Corbyn, M.B., M.R.C.S., late of Merivale, Beckenham Road, Beckenham, Kent.

On the previous Tuesday afternoon Dr. Corbyn, it appeared, came to town to meet Sir John Tweedy, of Harley Street, W., in consultation about a patient. Subsequently, accompanied by the patient, he went to the shop of Messrs. Curry and Paxton, opticians, Great Portland Street, W., where, within a minute or two of their arrival, Dr. Corbyn suddenly dropped on the floor. Life was found to be extinct by Dr. Florence E. Willy, of Devonshire Street, W., who was called in. Having made an autopsy, she ascribed death to syncope, consequent on advanced aortic disease of the heart. She was of opinion that death was instantaneous.

A verdict of death from natural causes was returned.

**Beri-beri at Shields.**

AN outbreak of beri-beri has been notified as having occurred on board the Brazilian cruiser *Barroso*, which recently arrived in Shields Harbour, after calling at several other English ports. Some men were removed to hospital at Shields after the vessel's arrival there, but were cured, with the exception of three, who are still detained. Sixteen others of the crew are now in hospital, where there are now in all 19 patients, all suffering from beri-beri.

**Coroner and Peculiar People.**

AT a recent inquest at Southend on Mrs. Rose Bundock, aged 52, a member of the Peculiar People, medical evidence showed that death was due to intestinal obstruction. Mrs. Bundock had declined to see a doctor. Dr. Silva Jones, who made a post-mortem examination, stated that, in his opinion, the deceased might have been relieved or cured by an operation which, however, would have been a dangerous one. The jury returned a verdict in accordance with the medical evidence. The Coroner (Mr. C. E. Lewis) said those who had attended the woman during her illness were morally responsible for her death. He was confident himself that if an operation had been performed the woman's life would have been prolonged, if not saved. He hoped they would bear in mind what he had said for the rest of their lives. But for the fact that the woman's complaint was a complicated one, he should have sent the depositions to the Director of Public Prosecutions.

**Death under Chloroform.**

AN inquest was held, at the Warrington Coroner's Court, on the 20th inst., into the death of Edward Howard, 2 years of age, who died whilst under an anæsthetic at the Infirmary. Dr. Johnson, Senior House Surgeon, said the child was admitted into the institution as an in-patient, suffering from adenoids. The child was prepared for the operation, and Dr. Green administered one drachm of chloroform, but before the operation was performed the child suddenly stopped breathing, and measures were at once used to resuscitate the child, but without success. The amount of chloroform used was, in his opinion, insufficient for the sudden stoppage of breathing. Death was due to respiratory failure caused by the obstruction in the air passages due to enlarged tonsils and an abscess. The jury returned a verdict of "Death from misadventure."

**A Midwife's Experience.**

AT an inquest on an infant recently, at Yarmouth, Mrs. M. Sutton, a midwife, asked by the coroner if she had had any experience, said that she had attended at the birth of 9,037 children in 55 years. She began, she said, when she was 20, and had never lost a single case. In one year she attended 500 cases, and had entered every one in a book. The coroner said this was a "record" in his experience, and he congratulated the witness.

**The London Medical Exhibition.**

THE Fifth London Medical Exhibition is announced to take place next month at the Vincent Square Hall. The great success of the previous exhibitions had been

due to the fact that the affair is restricted to medical men, a feature that will be fully maintained upon the present occasion. We understand that the intention is to make this a huge social function. Further details will appear in due course.

**Death Caused by Wasp Sting.**

AS the result of the sting of a wasp, Mary Jane Charteris, 26, who lived at Rosehall Johnstone, Dumfriesshire, has died. She was going into church on Sunday, when a wasp stung a finger of her left hand through the glove. She felt the pain during the service, and afterwards became faint, and had to be assisted to a doctor's house. Blood poisoning set in, and she expired after several days' serious illness.

**Royal College of Surgeons of England.**

THE next Primary and Final Examinations for the Diploma of Fellow of this College will commence on Thursday, November 4th, and Monday, November 22nd. Candidates are required to give not less than fourteen days' notice of their desire to present themselves for either of these examinations.

The Examinations for the Licence in Dental Surgery under the Old Regulations will commence on Friday, November 5th, and for those under the New Regulations on Friday, November 5th. Candidates intending to present themselves for this examination must address the Secretary (Mr. F. G. Hallett), Examination Hall, Victoria Embankment, W.C., from whom all particulars relating thereto may be obtained.

**The Royal University of Ireland.**

THE following have passed the Second Examination in Medicine (those marked with an asterisk may present themselves for the further examination for Honours):—

Upper Pass.—\*John H. Beverland, \*George H. Mahony, \*Thomas Marron, \*George R. Naylor, \*Patrick J. Walsh.

Pass.—Samuel Acheson, James P. Aiken, Thomas Black, Dominick J. Cannon, Francis L. Cleland, Thomas F. Colfer, Christopher Costello, Daniel J. Enright, Edward H. Fennessy, Llewellyn D. J. Graham, John E. Harford, Richard Hennessy, John R. Henry, John V. Holmes, William J. Hunter, B.A., Frederick Jefferson, James T. Kyle, Charles Lafferty, John McFadden, Edward McSorley, William M. Morris, Herbert V. O'Shea, John F. Rahilly, Walter N. Rishworth, John M. Sheridan, Thomas Smyth, B.A., Stanley P. Stoker, Harold V. Walsh, Samuel E. Watson.

The following have been exempted from further examination in the subjects set opposite their names:—Thomas M. Adamson, Chemistry; William Hickey, Anatomy and Physiology; Thomas F. O'Donoghue, Chemistry; John H. Pollock, Anatomy and Physiology; William Turner, Chemistry.

**St. Mary's Hospital Medical School.**

THE following gentlemen have been elected to Entrance Scholarships, subject to confirmation by the Governing Body of the Medical School:—

University Scholarships.—50 Guineas, Horatio Thomas, University Coll., Cardiff; 50 Guineas, T. H. Phillips, University Coll., Cardiff.

Open Scholarships in Natural Science.—£145, R. W. Davies, King Edward's School, Birmingham; £50, F. W. MacAlevey, Mount St. Mary's Coll., Chesterfield; £25, J. E. Cheesman, South-Western Polytechnic.

Epsom College Scholarship.—D. R. Alexander.

**Charing Cross Hospital Medical School.**

THE following Entrance Scholarships have been awarded:—The Epsom Scholarship (60 Guineas) to Mr. Duncan W. Pailthorpe; the Livingstone Scholarship (75 Guineas) to Mr. Francis J. Hallinan; the Huxley Scholarship (50 Guineas) to Mr. David B. S. Jones. An Entrance Scholarship has also been awarded to Mr. Harold W. Williamson (30 Guineas); an Universities Scholarship of 50 Guineas to Mr. J. Milton Davies; and an Universities Exhibition of 20 Guineas to Mr. Abel Evans, both of the London University.

## NOTICES TO CORRESPONDENTS, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

### SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs 15.12. Messrs. Dawson and Sons are our special agents for Canada.

### ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £3 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

"GALL-STONE" (J. H., Chelsea).—(1) By the Oaths Act, 1888, a person objecting to the ordinary form of taking the oath is permitted to swear, with uplifted right hand, in the Scotch fashion, at the same time declaring, "I swear by Almighty God (as I shall answer to God at the Great Day of Judgment) that I will tell the truth, the whole truth, and nothing but the truth." (2) "Billin," the composition according to Wright's Annual 1908 (p. 612), is an extract from folia helminthocorte, folia jaborandi, ranunculus albus, and folia tanacetii. Its action has been highly spoken of by various authorities.

A SURREY G. P.—The best way of treating nevus in infants is by multiple electrolytic puncture—carried out under a general anæsthetic.

### THE POSTMASTER-GENERAL AND THE POST OFFICE DIRECTORY.

A CORRESPONDENT informs us that recently he called the attention of the Postmaster-General to what appeared to be an arbitrary handling of medical qualifications in the London Post Office Directory. In answer the Postmaster-General denied any responsibility whatever for what appeared in that publication. Considering that the royal arms appear on the cover and that the work claims to be official, the sooner the Postmaster-General asserts his claim to control the book in question, the better for the public.

CHRISTIAN SCIENCE.—We have received another characteristic letter from Mr. F. Dixon. We have already said we cannot publish any more of these effusions. Mr. Dixon believes that every kind of disease can be cured by the ministrations and prayers of paid agents of Christian Science. No sane medical man will care to discuss this claim to miraculous powers that are purchasable at the price of 5s. and upwards for a seance. Mr. Dixon ends with this statement:—"That the fees received by Christian Scientists are, like those received by the doctors and the clergy, the natural adaptation of Jesus' words to the western habits of another age. If, he says, 'we have sown unto you spiritual things, is it a great thing if we shall reap your carnal things?'"

PATER.—The Army Medical Services, both British and Indian, now offer a very satisfactory career for men with a taste for military life, and afford certain roads to success in every sense of the word to those of superior capacity, and determined to work.

## Meetings of the Societies, Lectures, &c.

TUESDAY, OCTOBER 5TH.

ROYAL SOCIETY OF MEDICINE (THERAPEUTICAL AND PHARMACOLOGICAL SECTION) (20 Hanover Square, W.).—4.30 p.m.: A Discussion will be held on The Teaching of Therapeutics in the Hospital Wards. The Discussion will be opened by Sir Clifford Allbutt, Prof. Osler, Dr. Harrington Sainsbury, Dr. Calvert, Dr. Robert Hutchison, and Prof. Dixon will take part.

## Vacancies.

Hertford County Hospital.—Resident House Surgeon and Secretary. Salary £100 per annum, with board, washing, and apartments. Applications to the Chairman of the Board.  
City of Chester.—Assistant Medical Officer of Health. Salary £250 per annum. Applications to J. H. Dickson, Town Clerk, Town Hall, Chester.

The Hospital for Sick Children Great Ormond Street, London, W.C.—A House Surgeon. Appointment for six months. Remuneration £30, with board, washing, and residence in hospital; also Anæsthetist (honorary). For further particulars see advt.

County Asylum, Rainhill near Liverpool.—Assistant Medical Officer. Salary £150 per annum, together with furnished apartments, board, attendance, and washing. Applications to the Medical Superintendent.

Royal Buckinghamshire Hospital, Aylesbury.—House Surgeon. Salary £100 per annum, with board, washing, and lodging in the Hospital. Applications to Stanley E. Wilkins, Secretary, 25 Walton Street, Aylesbury.

Infirmity and Workhouse of the City of London Union.—Assistant Medical Officer. Salary £150 per annum, together with furnished apartments, rations, and washing. Applications to Edward R. Woodward, No. 61, Bartholomew Close.

## Appointments.

BROOMHEAD, C. H., M.B., Ch.B.Vict., M.B., B.S.Lond., House Surgeon at the Salford Royal Hospital.

BROWN, GEO. ABRUCKLE, M.B., C.M. (Hon.), B.Sc.Glasgow, Chief Medical Officer for the inspection of children under Govan School Board.

DESPREZ, HENRY SOULBIET, L.R.C.P. and S.Edin., L.F.P.S.Glasg., Medical Officer for the Northampton District by the Okehampton (Devon) Board of Guardians.

EVANS, RICHARD, M.R.C.S., L.R.C.P.Lond., Medical Officer to the No. 3 District of the Wrexham Board of Guardians.

GOUGH, WILLIAM, B.Sc., M.B., B.S.Lond., F.R.C.S.Eng., Honorary Assistant Surgeon to the Hospital for Women and Children at Leeds.

HOLDEN, WILLIAM, M.B.Edin., Resident Medical Officer to the Victoria Hospital, Burnley.

JONES, ARTHUR WILLIAM LLEWELYN, L.R.C.P.Lond., M.R.C.S., Medical Officer and Public Vaccinator for the Kingsteignton District by the Newton Abbot (Devon) Board of Guardians.

KERR, CHARLES, M.B., C.M.Edin., Clinical Medical Tutor in St. Andrew's University.

MACINTYRE, JOHN, M.B., C.M.Glasg., Inspector for the Medical Examination and Supervision of School Children for the County of Lanark.

MILNE, F. M., M.B., Ch.B., St. And., Lecturer in Clinical Pathology in St. Andrews University.

PARRY, T. WILFRED, M.B., Ch.B.Liverp., Assistant Medical Superintendent to St. Giles' Infirmary, Camberwell.

ROBERTS, ERNEST T., M.B., C.M., M.D.Edin., Chief Medical Officer for the inspection of children under the Glasgow School Board.

SHARPE, F. A., M.B., B.S.Lond., D.P.H., Senior Assistant Medical Officer of Health and School Medical Officer for the County Borough of Derby.

WALKER, E. A., M.B., Ch.B.Edin., Resident Surgical Officer at the Salford Royal Hospital.

WEATHERBE, PHILIP, M.B., Ch.B.Edin., Honorary Surgeon to the Children's Hospital, Halifax, Canada, and Associate Professor of Surgery to the Halifax Medical College, Canada.

Royal Isle of Wight County Hospital, Ryde.—Resident House Surgeon. Salary £125 a year. Applications to the Secretary.

Royal National Orthopaedic Hospital, 234, Great Portland Street, W.—Resident House Surgeon. Salary, £100 per annum, with board, residence, and washing. Applications to the Secretary.

Govan District Asylum, Hawkhead, Paisley.—Second Assistant Medical Officer. Salary £150 per annum, with rooms, board, laundry, and attendance. Applications to the Medical Superintendent.

## Births.

JACKSON.—On September 20th, at Bridlington, the wife of Dr. T. C. Jackson, of Hull, of a daughter.

LUND.—On September 25th, at 8 Collingham Road, London, the wife of Kenneth F. Lund, M.B.Lond., of a daughter.

MARTIN.—On September 20th, at Court, Cullompton, Devonshire, the wife of Captain J. F. Martin, R.A.M.C., of a daughter.

## Marriages.

CHIDELL—WESTALL.—On September 21st, at St. Matthias's Church, Richmond, Surrey, Claude Churchill Chidell, M.B., B.S.Lond., to Ethel Alicia Isabel, youngest daughter of the late William Westall, of Rydal, Worthing.

DINGLE—WHITELAW.—On Aug. 16th, at St. Michael's Sandakan, B.N. Borneo, Percival A. Dingle, M.R.C.S., L.R.C.P. (Lond.), son of W. A. Dingle, M.D., J.P. of London, to Norah, widow of Dr. T. Buchanan Whitelaw, Tyldesley.

DOUZY—WILLS.—On September 21st, at St. Paul's, Knightsbridge, Edward Henry Douzy, M.A., M.D., of Cannes, to Kathleen Mary Hamilton Wills, youngest daughter of the late Sir Frederick Wills, Bart., and Lady Wills, of 9 Kensington Palace Gardens, London.

GROGHEGAN—PICKTHORN.—On Sept. 23rd, at St. Mary's, Hammer-smith, Staff-Surgeon Herbert Lyne Groghegan, M.D., R.N., son of the late Stannus Groghegan, to Ella, only daughter of the late Inspector-General T. Russel Pickthorn, R.N.

WARE—MAUDE.—On Sept. 21st, at St. Mary's Church, Eastbourne, Arthur M. Ware, M.D., of 15, Launceston Place, De Vere Gardens, Kensington, to Edith Frances Maude, eldest daughter of Ashley H. Maude, J.P., Eastbourne.

## Deaths.

BISS.—On September 20th, at Eastbourne, Hubert Biss, M.A., M.D., D.F.H., aged 37, assistant Editor of THE MEDICAL PRESS AND CIRCULAR. Friends kindly accept this, the only intimation.

# THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIX.

WEDNESDAY, OCTOBER 6, 1909.

No. 14.

## NOTES AND COMMENTS.

**The Suffragettes and Forced Feeding.** THE fierce onsets of the Suffragettes have led to various variegated tactics in the ding-dong fight against law and order. When women take to throwing tiles from housetops on the heads of the crowd below most sober citizens will feel that it is time to interfere decisively, for they have, in such a case, forsaken the region of legitimate agitation for that of criminal lunacy. Indeed, it becomes a moot question whether many of these hysterical females are not mentally irresponsible for their actions. Can a sane woman, for instance, refuse food until she dies simply because the wisdom of the ages has so far refrained from granting her the Parliamentary franchise? It is open to doubt if a woman who starves herself on such a ground persistently and obstinately is one whit more responsible than the asylum lunatic who refuses food as a part of his madness and is promptly fed by means of a stomach-pump. One of the manoeuvres of the Suffragette in prison has been to refuse food, whereupon the authorities have hitherto been in the habit of granting them a discharge. But the move of starvation has been met by the countermove of hospital treatment and forced feeding by the agency of a stomach-pump. The usual question has been asked in the House as to the incident. It was answered by the Home Office explanation that "the treatment in such cases is the ordinary treatment which has frequently been applied both to men and women in the case of contumacious or weak-minded persons who refuse food."

**An Appeal to the Stomach.** THIS direct appeal to the stomach in reply to a bid for the crown of martyrdom suggests a sense of humour which one does not usually associate with the Home Office. Seriously speaking, however, there is no apparent reason why the Suffragette woman should be treated preferentially in prison because she is a political offender! When some unfortunate man has his face scratched and his coat torn by one of these infuriated women the question of politics does not enter into the case. Nor does the householder think unduly about the Parliamentary suffrage while contemplating his shattered dining-room windows. Nor would the friends of an unfortunate citizen whose skull had been cloven by a roof-tile hurled by way of political protest from a house-top be likely to try and stop criminal proceedings. There is no reason why criminal administration should be mitigated to meet the case of the Suffragette who commits an unprovoked and aggravated assault. As to forced feeding, if it is a plain and bounden duty of prison officials to resort to it in the case of ordinary

contumacious or feeble-minded prisoners, why not of the Suffragette who, by her absurd actions, places herself within either category? It seems to the writer, as a medical man not altogether unversed in the ways of mentally irresponsible persons, that a woman who deliberately starves herself under the circumstances in question can hardly be sane. Anyway, the Home Secretary has acted decisively and the outside public awaits the next move with not a little amusement.

**"Home Remedies."** ONE hopes that as the ages speed along the general spread of education may lead to an intelligent appreciation of some of the more important principles of medical science. After all, it may be not so much a matter of recognition as of application in practice, for our forefathers in earliest times framed the familiar proverb that "cleanliness is next to godliness." Some of the educated classes have profited by the surgical experiences of themselves and of their friends and apply the principles, for instance, of asepsis in the home circle. Not long ago the writer heard a medical man relate with glee how a certain learned barrister, having scalded himself by accident, dressed the wound with antiseptic dressings and cut away the blisters that formed later with scissors that had been boiled for ten minutes. Culture of that highly specialised degree, however, will probably take a long time to filter through to the man in the street. Meanwhile, a vast proportion of our fellow countrymen trust to home remedies applied to minor injuries without regard to the refinements of aseptic methods. At a recent inquest in Manchester upon a child who had died from erysipelas, which came on three weeks after vaccination, the mother admitted she had taken the dressing off and rubbed some cold cream into the pock with her fingers. This meddlesome use of a "home remedy" cost the life of the child and has furnished a case that will doubtless figure largely in future anti-vaccination literature.

**The Culture of Medicinal Plants.** At the opening ceremony of the Pharmaceutical Society's session on Wednesday last, an address on the above-named subject was delivered by Professor Tschirch, Rector of the University of Bern. The most interesting passage of the address was perhaps that devoted to discussion of the problem: "In what way is it possible by suitable cultivation to increase the amount of this or that constituent of a medicinal plant, and to diminish the quantity of any other constituent that may appear to be an undesirable ingredient, Professor Tschirch presented ample evidence in support of his belief that by variation of conditions of cultiva-

tion; by careful selection of suitable strains; by crossing, grafting and by other means brilliant results can be obtained. In most of such experiments the first sod has only just been turned. The experience gained in cultivation of cinchona has, however, already made the attainment of definite results seem very possible; so that the production of a cinchona bark rich in quinine, and containing only small quantities of other alkaloids, and of an opium poor in narcotine, appears well within the grasp of science. An increase in the amount of valuable constituents has been effected in the case of almost all cultivated plants, a fact which disposes of the popular error that wild ones are always—and without exception—the better for pharmaceutical purposes.

## LEADING ARTICLES.

### THE MEDICAL PROFESSION ON COLLECTIVE DEFENCE.

OF recent years the medical profession have on various occasions and in various ways exercised their power collectively, in other words, they have learnt to some extent the art of organisation. The friendly societies and the local Poor-law authorities, for instance, are no longer able to ride roughshod over the interests of a "disorganised rabble," but nowadays find themselves called upon to face a strong and powerful Association numbering upwards of 20,000 members. By means of a "black list" medical men are warned against applying for appointments in which either the salaries or the terms and conditions of the post are derogatory to the dignity and the deserts of the medical profession. That the "black list" is by no means a perfect weapon of defence is shown by its apparent failure in the Hampstead Hospital case, which two annual representative meetings of the British Medical Association have apparently failed to push to a conclusion. Then, again, there is no means of dealing effectively with medical men who apply for medical aid or Poor-law posts that have been publicly banned by the authoritative voice of the majority of their fellows. For all that, a vast deal has been achieved in the education of the public as to the facts of the Public Medical Service, which is an absolute and real necessity to the welfare of the community. The principle involved in collective self-defence is frankly that of trades unionism. However much the term may have been disliked by a former medical generation, it should be borne in mind that their refusal to look the business side of professional life frankly and squarely in the face has been, to a great extent, answerable for the present state of affairs, in which every social and political organisation appears to regard medical men as *par excellence* the natural agents for the exercise of vicarious charity. One of the meanest of all these impositions is that disclosed by the recent Report of the Poor-law Commission, which says, for example, "It is undeniable that the majority of medical officers, in- or out-door, are paid salaries miserably inadequate." And again, "There is a policy of sweating, both as to the amount of work required and as to the payment made for it." Possibly,

when the long-awaited Reform of the Poor-law is at hand we shall find the salaries of medical men fixed on a liberal scale by a strong central administrative authority instead of by parsimonious local boards. Fortunately, in this case it would be out of the question for the State to attempt to get the work done gratuitously, as was done in the recently imposed duty of the registration of births—because even a struggling profession must draw the line somewhere. The medical work of the voluntary hospitals is for the most part unpaid, but if the State were to ask gratuitous medical service for the Poor-law their various organisations would speedily be unstaffed. Yet the State is doing something of the kind indirectly by permitting school boards to apply to voluntary medical charities for the treatment of defective school children. It is devoutly to be hoped that the members of the staff of certain London hospitals—some of which have played into the hands of the enemy—will refuse to betray their professional brethren in the demand for proper remuneration for the discharge of this particular duty, namely, the skilled medical treatment of school children. The fact is that the medical profession as a whole has not yet learned the value of collective action. Their united strength is well nigh unbounded. Supposing a general medical strike were declared the business of the nation would be brought to a standstill. What would happen if there were no medical men—even for a single day—to attend to the accidents and the sickness that affect society? The suggestion of such a situation may appear remote and fanciful, but it is founded on a basis of solid fact, inasmuch as the life of the nation could not be conducted in a satisfactory manner, even for a single day, without the incessant ministrations, paid and unpaid, of the medical profession. The time appears to be now at hand when medical men are learning the vital necessity of combination for the purpose of collective defence. The art in question has long ago been acquired by the lawyers, who, in the course of many generations, have unobtrusively entrenched themselves in an unassailable position. One good thing to be learnt from the legal profession is the need of a strong body armed with full powers for the prosecution of false practitioners, and that is doubtless one of the first matters to which a popularly elected and representative General Medical Council will give their earnest attention.

### SANITATION AT GRAVESEND.

DR. R. J. REECE's report to the Local Government Board on the sanitary administration of Gravesend discloses a state of things to which the cant phrase, "truly appalling," seems for once quite applicable. In this matter Gravesend does not, however, stand alone. We are frequently pointing out, and quite lately we proved, with regard to some thirty urban and rural districts in Yorkshire, that the fundamental requirements of health laws are being more or less systematically neglected widely throughout the country. On occasion we have insisted that the fault lies almost

invariably with the public. Ratepayers refuse to take interest in local affairs, and, in consequence, men of capacity and independence decline to serve on the authorities. In many places the authorities are dominated by mean and ignorant men who seem incapable of understanding the importance of sanitary laws, whilst their sole preoccupation is to keep down the rates at any cost. Besides this, a contingent of such boards often consists of men who hold their positions with the set purpose of preventing the administration of laws which conflict with their own personal sordid interests. On a body so made up a minority of enlightened, earnest men are, of course, powerless. They are continually outvoted, whilst public opinion, to which they might appeal, is altogether lacking. It is not to be wondered at, under those circumstances, that the chief officials of the Local Government Board seem, as we lately suggested, more and more in favour of substituting the rule of the Board, a system, in fact, of bureaucracy, for the present so-called democratic rule—a rule in which the bulk of citizens decline to take part, and which, therefore, in the true sense of the word, is far from democratic. Beyond the fact that Gravesend is a borough with a Corporation, Mayor and Town Council, we know nothing about the constitution of the authority, and cannot judge upon whom, if upon any individuals, the blame for the present shocking conditions lies. In the first place, the medical officer is engaged to devote only a part of his time to duties which Dr. Reece declares are enough to occupy the officer fully; and an additional sanitary inspector is, moreover, needed. We have over and over again described the position of humiliation, and even degradation, in which medical officers of health find themselves under conditions that seem to prevail at Gravesend. They are the servants of the authority; it is as much as their place is worth to protest against abuses which their masters choose to tolerate; any public speech, or disclosure through the press, would mean dismissal; the most they can do is mildly to expostulate with the sanitary committee when sitting in private. The population of Gravesend is upwards of 30,000 living on an area of 1,253 acres. There are very few sewers, and these lack efficient flushing and ventilation. Nearly the whole sewage of the town is collected in cesspools. These vary in depth from a few feet to sixty feet or more. There exist no binding regulations as to the distance from houses the cesspools shall be sunk, or as to their situation, so that in many instances they are within a few feet of each other, quite close to dwellings, and in a few cases beneath them. In the last eight years 550 cesspools have been added to those previously in use, the total being now over 6,000. Only about 1,000 of these receptacles are emptied annually, but many have not been emptied for thirty years, and many have never been emptied at all. In some cases, when the cesspool has become full, the drains have been connected with the house wells—the water being no longer needed for domestic purposes, owing to the extension of the water company's service. Most of the wells are deeper than the cesspools, and,

penetrating the water-bearing strata of the chalk, form possible sources of contamination of the water company's wells, and perhaps of more distant sources. The fact that the Thames Conservancy recently took proceedings against the Town Council for polluting the Thames is suggestive; the case remitted from the local Bench is now to be tried in the High Court. This story of the cesspools alone forms a tolerably strong indictment of the Gravesend authorities. They seem to have prepared the ground for a virulent outburst of disease; the magazine is filled, the train laid, and it depends upon a chapter of accidents whether or not an explosion shall follow. If they do not make haste to put their house in order, the Gravesend authorities may find themselves, like their Maidstone neighbours, some years ago, in a situation from which they will not emerge without being made to witness much misery, to deplore the loss of many valuable lives, and to face an expenditure much greater than could have been needed to render such a calamity altogether impossible. Finally, the Town Council might well bear in mind the fact that in the event of an outbreak of typhoid fever arising from their negligence, they would be liable for damages to every inhabitant or visitor who should suffer from the disease.

---

## CURRENT TOPICS.

### Medical Referees.

THE provision for the appointment of medical referees to sit on the bench with judges and to give impartial advice was one of the good features of the Workmen's Compensation Act. There has been some delay on the part of the Home Secretary in filling up these appointments, for reasons that are not apparent to the outside world. The question has been recently revived, and it is to be hoped that Mr. Herbert Gladstone will now take some more decisive steps towards providing an adequate supply of medical referees. The experience of the working of the new Act has shown that most of the cases hinge on medical points, some of them of an obscure and highly technical nature. No layman can possibly arrive at a satisfactory conclusion with regard to these difficult investigations, especially when faced with conflicting evidence from medical witnesses on either side. The latest suggestion is that the medical referee should replace the medical witnesses, but that his examination of the plaintiff (or defendant) patient should be made in the presence of the medical men engaged on both sides. It would obviously tend towards raising the dignity of the medical profession if some such course were adopted, and it would probably assist in advancing the ends of justice. For our own part THE MEDICAL PRESS AND CIRCULAR has for a long time advocated the establishment of a medical board of referees for all courts of justice, from police courts upwards.

### Wage Deduction for Medical Attendance and the Truck Act.

AN important decision was recently given in the Dunfermline Sheriff Court. The pursuer sued the Fife Coal Company for 1s. 6d., being three fortnightly sums of 6d. deducted from his wages

on account of medical attendance. Sheriff Shennan said that "There is no doubt that, under Section 25 of the Truck Act, 1831, a deduction for medical attendance is legal, provided that the agreement for such deduction shall be in writing, and signed by the workman. It is admitted that on every payline signed by the pursuer his receipt embodied an authorisation to the defenders to deduct from my wages in future so long as I am in your employment the amount of my house rent, also the sums paid by you for medicine and medical attendance." Although the Sheriff said there were sufficient grounds for settling that particular case, it was nevertheless easy to see that difficult legal questions might be raised, but these he did not propose to raise and discuss. At the same time he expressed a hope that an earnest attempt would be made to avoid future misunderstandings, and concluded with the highly sensible and practical remark that in the medical sphere the interests of masters and men were identical. It seems a pity that the medical profession should be involved in an industrial wrangle of so narrow and paltry a nature as that involved in the above case.

#### Science and Tropical Disease.

THE rapidly increasing control of tropical disease by medical science has formed a permanent theme in these columns recently and during late years; it is strikingly illustrated once more in the report on the health of Sierra Leone just presented to the Colonial Office by the Governor, Mr. Leslie Probyn. Thanks to the discovery that the disease is due to the bites of infected mosquitoes, the scourge of malarial fever has been materially abated, and the sobriquet, once well justified, "the white man's grave," has become a libel on the Colony. The improvement is ascribed almost entirely to the untiring zeal and labours of the medical officers. Their teachings have made colonists and natives alike to realise the fact that by quite easy precautions—including temperance—disease once thought unpreventable may be almost entirely avoided. The new knowledge has become widespread. It is taught in the native schools; and the Protectorate natives of Free Town, about one-third of the population, enter seriously upon the task of keeping their compounds clean and free from stagnant water. The total statistics of Free Town demonstrate the efficacy of these measures. In 1907 the deaths from malarial fever numbered 202; last year they dropped to 150. The Municipality makes strenuous endeavours to keep the natives up to the sanitary mark, whilst the chiefs in native towns are stimulated to action by the presentation of prizes in the form of handsome swords—gifts which they are very anxious to acquire and to keep, and this they can only do by maintaining their towns in a good sanitary condition. It would be pleasant if it could be added that the labours of the medical officers in thus preventing the sacrifice of human life at the risk of their own had been rewarded by honours and gifts such as are usually lavished on other servants of the State whose achievements—like, for example, those of soldiers—strike more possibly the imagination, but are in no sense more valuable to humanity or to the Empire.

#### Socialism and the Profession.

THE *Anti-Socialist* prints the following questions and answers taken from one of the lessons in the "Red Catechism" compiled for the use of children in Socialistic Sunday Schools:—

"Have poor people objections to the present hospitals?—Yes. They are afraid that the students and the doctors will make experiments upon them. Why do doctors make experiments upon poor people? Because it gives them experience which they can sell to the rich. Are hospitals used as training schools for young doctors? Yes. Do students practice upon the rich?—No. The rich will not tolerate it."

The *Anti-Socialist* states that in the Socialistic press the medical profession has been the object of unscrupulous and malignant attacks more than any other section of the community except the capitalists. Seeing that the profession is the only one which constantly gives its services to humanity without fee or reward, our contemporary fails to understand these attacks on any rational grounds, and characterises them as one of the most extraordinary features of the Socialistic campaign. The feelings which these calumnies express are, we believe, to be accounted for, at least in some measure, by the anti-vivisectionist and anti-vaccinationist propaganda, which are directed mainly to the poorer and more ignorant classes. Persistently and, for many years, the anti-vivisectionists have virtually held up the profession to execration as the supporters of "anti-human wretches," who devote their lives to the infliction of torture upon dumb brutes, well knowing that the results must be of more than doubtful value. The anti-vaccinationists have in the same way constantly charged the whole profession—those whose duties do not include vaccination, as well as those who perform the operation—with carrying on for paltry gain a gigantic conspiracy by which a loathsome poison is disseminated among the people, including the doctors' own children, whom they sacrifice to cloak their hypocrisy. Fortunately the good faith of the medical profession is appreciated by the vast majority of our countrymen.

#### Public Health Administration in Ireland.

IN a special article last week we drew attention to the curious discrepancies between the reports of two public servants regarding the lamentable outbreak of typhoid fever which occurred in one of the residential suburbs of Dublin twelve months ago. The Clontarf outbreak was investigated by Sir Charles Cameron, for the local sanitary authority, the Corporation of Dublin, and by Surgeon-Colonel Flinn for the Local Government Board. Under such circumstances the public had a right to expect that there should be a thorough scientific investigation, that blame should be properly apportioned, and that steps should be taken to prevent further outbreaks from similar causes. None of these expectations have been fulfilled. The many discrepancies between the reports of Sir Charles Cameron and Surgeon-Colonel Flinn, the carelessness in neglecting to ascertain easily ascertained facts, and the contradictory conclusions reached,

leave us without any certainty that either report is to be regarded as accurate or thorough. Both cannot be accurate, and one of them must be seriously and culpably inaccurate. Differences in conclusions may be inevitable, since conclusions are to a great extent matters of individual judgment, but the public has a right to demand a strictly accurate account of the facts of such a grave outbreak of disease as that which occurred in Clontarf last year. Theories or hypotheses, without a foundation of uncontested facts, are of no value, and are merely trifling with the public intelligence. As regards the apportionment of blame, no conclusion is stated. Finally the failure of the Corporation to prevent the distribution of milk which they fully believed to be infectious shows how much was done to limit the outbreak or prevent its recurrence. We have had, on many occasions, to draw attention to serious flaws in Irish sanitary administration. The reports on the Clontarf outbreak go far to take away our last shreds of confidence.

### Forced Feeding.

THE knowledge that certain prisoners have been subjected to methods of forced feeding to prevent them injuring their health by voluntary starvation seems to have caused much disturbance to the public mind within the last few days. The sympathy expressed with those whose bodies have been thus "outraged," to quote Mrs. Pankhurst's term, is, of course, as far as physical suffering is concerned, quite wasted. The process of feeding by a nasal tube is, as every prison surgeon and asylum physician knows, quite simple, and entirely painless. The statement of one member of Parliament that "the last man treated that way died" is so grossly ignorant as to be ridiculous to those who know that every day of the year hundreds of "contumacious and weak-minded persons" are thus saved from the effects of their own folly. For our part, we have wondered why so old a prison dodge as refusing food should have been permitted to produce the desired effect in the case of a certain class of prisoners, while with others it was met by the usual safeguards, and we cannot regret that prison discipline is to be more equally administered in future.

### PERSONAL.

It is stated in a Reuter telegram that arrangements have been made by which King Edward will take part in the opening of the new Royal Edward Tuberculosis Institute in Montreal. His Majesty will press a button in Buckingham Palace in London, which, by electrical communication, will throw open the doors, turn on the lights, and hoist a flag on the building.

PROFESSOR SCHOLT, of Nauheim, will deliver the introductory address at the West London Post-Graduate College, on October 11th.

MR. CHARLES A. BALLANCE, M.V.O., yesterday delivered the inaugural address in the Arts Theatre of the University of Liverpool.

At Charing Cross Medical School, on Monday last, Viscount Ridley was unable to distribute the prizes, as had been arranged, and his place was taken by Sir T. Clifford Allbutt.

DR. THEODORE DAVIS, of Haslemere, Walton-in-Gordano, Clevedon, who died on August 11th, aged 75, left estate of the gross value of £17,213, with net personalty £16,178.

At the opening of the winter session at Guy's Hospital, on Friday last, of the medical school attached to that hospital, Sir Hector Cameron addressed the first autumn meeting of the Pupils' Physical Society on certain aspects of Lord Lister's antiseptic treatment as applied to abscesses.

SIR WILLIAM MACGREGOR, who sails on October 15th to take up his new duties as Governor of Queensland, was recently entertained at luncheon, with a distinguished company, by Sir Alfred Jones, K.C.M.G., Chairman of the Liverpool School of Tropical Medicine.

DR. THOMAS CRAWFORD HAYES, of Clarges Street, Mayfair, W., Emeritus Professor of Medicine at King's College, who died on April 5th, left estate of the gross value of £50,739 8s. 5d., of which the net personalty has been sworn at £48,765 7s. 3d. He left £100 to the King's College Hospital Building Fund.

INTERESTING presentations were made last week to Mr. Chas. Lakin, Mayor of Leicester, and to Dr. Robert W. W. Henry, from the blind people of the town, and the Council of the Wycliffe Society for Helping the Blind. They were in recognition of many years of honorary service to the institution mentioned, Mr. Lakin as physician, and Dr. Henry as ophthalmic surgeon.

MR. HENRY GORST, of Summerdale, Liverpool, surgeon, who died on June 19th, aged 54, left estate valued at £29,955 gross, with net personalty £28,177. He left £50 for distribution in the form of food, coal, and clothes amongst the poor of the district. He also stated:—"I forgive all debts due to me at the time of my death for professional services by persons whose net wages do not exceed 30s. per week."

ON the 1st October, Lord Justice Fletcher Moulton delivered an address at the opening of the winter session at the Leeds School of Medicine. The subject was "Some Thoughts on Causation in Health and Disease."

DR. G. A. GIBSON, of Edinburgh, has been offered, and has accepted, the honorary degree of D.Sc., Harvard University, and has sailed for America to receive it.

IN giving judgment in a recent case at Clerkenwell County Court, London, Judge Edge said that in cases where the question was purely one of medical evidence, it would be much better if, instead of bringing the matter before a judge in court, a rota of leading medical and surgical practitioners in London were formed by the authority of the Home Secretary. Then, in cases of that sort, the medical men on each side could agree upon some member of the rota who should examine the patient in the presence of the medical men on both sides, and whose report to the Court should be taken as conclusive.

# A CLINICAL LECTURE

## ON

### CANCER OF THE TONGUE. (a)

By R. ATKINSON STONEY, F.R.C.S.I.,

Visiting Surgeon to the Royal City of Dublin Hospital.

THE subject for consideration this morning is cancer of the tongue, with particular reference to those cases where the disease starts on the side of the tongue and involves the floor of the mouth at an early stage. Here is a case in point:—

CASE I.—The patient, a man, æt. 60, first noticed a sore under the tip of the tongue about six months ago; it was not very painful. After a short time he showed it to a doctor, who advised him to have it removed. However, he did not take his advice, and only came to hospital a few days ago. On looking into the mouth, it is seen that the tongue is bound down to the floor of the mouth and cannot be protruded, an ulcerated surface is seen between the tongue and the back of the symphysis, and on tilting back the tip of the tongue this ulcer is seen to cover the under surface of the tongue, the floor of the mouth, and the muco-periosteum on the back of the jaw right up to the level of the teeth; it extends from the left lateral incisor to the second right bicuspid; the edges are everted, thickened, and hard; the ulcer bleeds readily, and there is an offensive smell from it. Let us now examine for enlarged glands. These can be both seen and felt in the middle line under the symphysis, and in both submaxillary regions, those on the right side being very large and hard. None can be felt below the level of the hyoid bone on either side. When examining for enlarged glands, it is most important that the tissues of the neck should be relaxed. The best method is to seat the patient in a chair, and, standing behind him, make him bend the head slightly forward, and then palpate the neck with one hand on either side. Owing to the fixity of the tongue and pain, the patient has great difficulty in taking nourishment, and, as you notice, his speech is very indistinct. This is not a very suitable case for operation. First of all, though the patient says he is only sixty, he looks at least seventy, and is evidently in a feeble condition. Secondly, the extensive involvement of the floor of the mouth and the back of the jaw will necessitate an extensive operation, probably including a removal of a portion of the bone; it will certainly require a division of the bone in order to allow of free access to the disease. Thirdly, the glands are affected to a considerable extent on both sides, though the fact that none can be felt below the submaxillary triangles is a point in his favour. In spite of these objections, however, operation should be advised owing to the great pain and disability that the patient suffers, and the fact that, if not operated on, the difficulty in taking nourishment, and the constant swallowing of septic material from the mouth must lead to rapid wasting and an early fatal result.

I will now show you two other cases of a somewhat similar character that have been operated on.

CASE II.—J. L., a man, æt. 45, was admitted to this hospital in September, 1907. He had an ulcer on the right side of the tongue and floor of the mouth; he had noticed it first some three months before I saw him. The ulcer did not extend to the middle line, and did not involve the muco-periosteum of the jaw; glands were palpable in the right submaxillary triangle. The operation performed was one which I shall describe more fully presently; glands were

found crossing the middle line below the symphysis, and both submaxillary triangles were completely cleared; the jaw was divided just to the right of the symphysis, and about two-thirds of the anterior portion of the tongue and the right side of the floor of the mouth were removed. The patient recovered rapidly, and left the hospital in about three weeks, the wound in the neck healing by first intention. There was considerable delay, however, in the union of the jaw, which was wired at the close of the operation. In July, 1908, he was seen again, and showed a recurrence which involved the stump of the tongue, the back of the symphysis, and the intervening part of the floor of the mouth. This time, the central portion of the lower jaw from the second molar on the right side to the first molar on the left was removed in one piece with the floor of the mouth and the remains of the tongue. Again he healed up rapidly, and left hospital in less than three weeks. He returned in November last with a small hard ulcer on the mucous membrane covering the left side of the jaw. This was found to be adherent to the bone, so a third operation was performed, and the whole of the left half of the jaw was removed. At the same time, a gland which was felt close to the bifurcation of the left carotid was removed and examined, but it showed no trace of malignancy. The patient was out of bed on the fourth day and left hospital at the end of a fortnight. You can see for yourselves that now he shows no sign of disease in the mouth and there are no glands to be felt in the neck. He can take his food well, can do a good day's work, and can speak fairly distinctly.

CASE III.—J. C., a man, æt. 47, was admitted last December with a large malignant ulcer on the right side of the tongue and floor of the mouth, involving the muco-periosteum of the right side of the jaw, and extending back almost to the anterior pillar of the fauces and forwards to within about half an inch of the middle line. Enlarged glands could be felt in the right submaxillary space, but not in the left. The patient had noticed the sore for nearly four months. The right submaxillary triangle was cleared out, the jaw was divided at the symphysis, and the anterior part of the tongue on both sides and on the right side the posterior part to behind the anterior pillar of the fauces, was removed, with the right side of the floor of the mouth, and all the muco-periosteum from the inner aspect of the right side of the body of the mandible. When the jaw was divided and the two sides separated, this muco-periosteum on the right side stripped up off the bone leaving it quite bare. I was afraid that this would lead to necrosis of the bone, and, in order to try and prevent this, I stitched the mucous membrane of the remains of the tongue over the bone to the muco-periosteum on its outer surface. The wound in the neck healed rapidly except for a small sinus which discharged for some months till a spicule of bone came away; after this it healed, and the two halves of the jaw which had been wired became firmly united about four months after the operation. There is now no sign of disease, and the only complaint is that saliva runs from the mouth when the patient stoops; this is probably due to the fixation of the tongue, the result of stitching the mucous membrane to the muco-periosteum on the outside of the jaw, but is a trifling disadvantage compared to the gain of saving the right half of the

(a) Delivered to the Post-Graduate Class of the Royal College of Surgeons of Ireland, at the Royal City of Dublin Hospital, on June 25th, 1909.

jaw. The patient can speak well, and has returned to work.

The only operation which I consider suitable to these cases of extensive cancer involving the floor of the mouth, is one in which the jaw is divided and the two halves separated. It commonly goes by the name of Sédillot's operation. I perform it as follows:—An incision is made from the symphysis in a curved direction down to the greater cornu of the hyoid bone and then up to the angle of the jaw, the skin and platysma are reflected upwards in a flap and the whole of the contents of the submaxillary space are removed from below upwards in one mass, including the submaxillary gland. It is most important that this gland should always be removed, as it is so intimately associated with the lymphatic glands that it is impossible to be sure of having removed all the latter if the submaxillary salivary gland is left behind. The facial vessels are divided between ligatures at the commencement of the dissection and the lingual is usually tied at the same time. If glands are palpable on both sides or if the primary disease in the mouth encroaches on the middle line, this dissection must be carried out on both sides. After ligature of all bleeding points the wound in the neck is packed with iodoform gauze and the second stage of the operation is now commenced. The lower lip is divided in the middle line down to the commencement of the incision in the neck, and the lower jaw is sawn close to or through the symphysis, the two halves are separated and held apart, and the diseased portion of the tongue and the floor of the mouth are removed with a wide margin of healthy tissue, at least half an inch. In this way the primary disease in the mouth and the secondary disease in the neck and the intervening tissues are removed in one continuous mass without cutting into them, and the operation corresponds to that which is now recognised as the ordinary procedure for cancer of the breast, or, indeed, for cancer in any part of the body. As much of the tongue and floor of the mouth can be removed as is deemed advisable, even the base of the tongue down to the hyoid bone, if necessary. The mucous membrane of the remains of the tongue is now stitched to the muco-periosteum of the jaw so as to shut off the mouth cavity from the wound in the neck; the two halves of the jaw are drilled and united by wire, and the skin incisions closed after removal of the gauze packing from the neck. A small opening is left under the angle of the jaw on one or both sides with an untied suture, through this opening a small gauze drain passes into the submaxillary space; this drain is removed at the end of 24 or 48 hours, and the suture tied if there is not much discharge. In this way the wound in the neck will usually heal by first intention. If the glands in the neck below the submaxillary triangles are involved they must also be removed at the commencement of the operation, by an extension of the skin incision vertically downwards from the greater cornu of the hyoid bone. This is undoubtedly an extensive operation and takes a considerable time, especially if both sides of the neck require to be done, but it is accompanied by surprisingly little shock, as a rule, and there is very little blood lost if the dissection is carried out as described from below upwards. This is the operation which was performed on the two cases you saw this morning and which I intend performing on the first case you saw. Those of you who care to do so can see it done after this lecture. This is very similar to the operation described by Mr. C. P. Childe in the *British Medical Journal* for January 2nd, 1909, except that he, like many others, advises that it should be divided into two stages separated by an interval of days or weeks. The advantages claimed for doing the operation in two stages are that the shock is less and the danger of infecting the large wound in the neck is removed. The disadvantages are that it involves two major operations instead of one, and it is often difficult, if not impossible, to get patients to agree to this; also it prevents the primary and secondary disease, and the intermediate infected tissue being removed in one continuous mass,

and it necessitates the cutting into infected lymphatics, and therefore probably increases the dangers of recurrence. The shock, as I have already said, is not usually marked in these cases, and may be guarded against by saline infusion, either during or immediately after the operation. The danger of septic infection of the wound in the neck can be largely prevented by the precautions indicated above, i.e., packing the neck wound during the later stage of the operation and forming a new floor to the mouth.

There are numerous dangers in any operation performed for the removal of extensive malignant disease of the mouth. The following are the most important:—

1. *Suffocation from blood getting into the larynx and trouble with the anæsthetic.*—In order to obviate these dangers and difficulties it has been proposed to perform a preliminary tracheotomy, either at the commencement of the operation or a few days before, and then plug the pharynx and administer the anæsthetic through the tracheotomy tube. This necessitates an extra operation or adds to what is already a very extensive procedure; it has been said that the mortality with tracheotomy is greater than without it, but this is only natural, as it is reserved for the worst cases. Instead of this it has more recently been advised to commence the operation with a preliminary laryngotomy. This is much better than a tracheotomy as it only requires a minute or two to perform it, but it is unnecessary, I think, where the above described operation is done, for in the early stages of this operation there is no interference with the anæsthetist, and when the disease in the mouth is attacked, owing to the division and separation of the two halves of the jaw, any blood which is shed tends to escape forward, and by placing a small sponge far back in each side of the mouth and administering chloroform with a Junker's inhaler there is no trouble either with the anæsthetic or with blood getting into the pharynx.

2. *Shock.*—This has already been considered. If owing to the condition of the patient, it is thought that shock is likely to be excessive, then the operation must be done in two stages. The removal of the glands should be undertaken first, as by this means the lingual and facial arteries can be tied, greatly lessening the loss of blood in the final operation; and also on account of the fact that if the removal of the tongue is undertaken first the patient may refuse to have the glands removed afterwards.

3. *Hæmorrhage.*—This may be primary or secondary. The hæmorrhage during the operation is slight, as the main vessels are secured during the early stage of the operation, and in the later stages the access to the mouth is so free that there is no difficulty in clipping any vessel which may bleed. Secondary, hæmorrhage is mainly a matter of sepsis, and as healing, specially of the neck wound is usually rapid, there is little danger of its occurrence. It has been suggested that a preliminary course of calcium chloride or lactate should be given, but this is hardly necessary.

4. *Sepsis.*—This may be largely prevented by care in checking all hæmorrhage in the neck and plugging it with iodoform gauze before the mouth cavity is opened, and at the end of the operation shutting off the neck wound by forming a new floor to the mouth. If this is done, as in the two cases I showed you, the wound in the neck heals up almost, if not entirely, *per primam*. Much can be done also by careful cleansing of the mouth and teeth before operation, with antiseptic mouth washes, the free use of a toothbrush (specially in the case of hospital patients) and the frequent use of lozenges containing some preparation of formalin (formamint lozenges are excellent) for several days or a week before operation. The use of these lozenges is the best means of keeping the mouth clean after operation and they are most pleasing to the patient, who readily sucks them when the mouth is too sore to allow of its being rinsed out with any comfort. It has been recommended that the patient's resistance to the action of the pyogenic organisms should be increased by in-

jections of anti-streptococcic and anti-staphylococcic serum for some days before and after the operation.

5. *Septic or Inhalation Pneumonia*.—This is probably the most serious danger in these cases, and the most difficult to guard against. It is claimed by the advocates of a preliminary laryngotomy or tracheotomy that by this means the danger of septic pneumonia is prevented, but this is only so if the tube is worn for several days, and even this precaution will not necessarily prevent its onset. It may be caused by the entrance of septic matter, blood or food into the larynx, either during the operation or at a later date. I have already explained how that in the operation described above there is practically no danger of the entrance of any foreign substance into the larynx during the operation. The likelihood of its occurring afterwards increases in direct proportion to the amount of the tongue which has been removed, owing to the part which is left being too small to cover the entrance of the larynx during the act of swallowing. But even in cases where the removal of the tongue very far back is necessary, the danger may be largely overcome by careful preliminary cleansing of the mouth, by getting the patient to sit up in bed, and even to get out of bed as soon as possible after the operation. The patient may be propped up after twenty-four hours, and may, in many cases, be got out of bed on the third or fourth day. All food by the mouth should be withheld for the first twenty-four hours, the patient being fed by the rectum. After this the patient should sit up when taking nourishment, or if not able to do so, a feeder with a rubber tube passed to the back of the pharynx should be used. A stimulating expectorant may be given with advantage, and the patient encouraged to cough and spit out any discharges which may collect in the mouth.

6. Another danger which is described, and which sometimes causes a sudden fatality after a successful operation, is suffocation from the slipping back of the stump of the tongue over the entrance of the larynx. This, of course, cannot occur when the remains of the tongue is stitched to the muco-periosteum of the jaw as advised. In cases, however, where the stump is very small and this cannot be done, a thick silk ligature should be passed through it and brought out of the mouth and fastened either with a piece of strapping to the cheek or tied round the ear, this should be retained for the first four or five days at least till the tongue has formed adhesions which will prevent its sudden falling back.

The results of operation for the cure of cancer of the tongue are not good, the disease recurring either locally or in the glands of the neck in a large number of cases. Why is this? Chiefly because the cases are not operated on in a sufficiently early stage. Whose fault is this, is it the fault of the patient or the doctor? When one considers the inconvenience caused by such a little thing as a blister on the tongue, it is hard to imagine that a patient can have an ulcer on his tongue for any length of time without being fully aware of it, and though exceptionally a patient will continue to endure the unpleasantness, if not worse, that it causes for a long time before showing it to a doctor, yet in the majority of cases it is seen by a doctor in the early stages. Why then is its removal not advised at once? The usual excuse is, that the diagnosis is not certain, and much valuable time is lost in coming to a decision that the disease is cancer. If an ulcer appears on the tongue of an elderly patient, especially a man, even if there is an apparent cause for it, as the irritation of a ragged tooth, the probability is that it is cancer or will develop into cancer. Therefore the rule should be that if an ulcer of the tongue in such a patient does not rapidly heal (not merely get better) under ordinary or specific treatment, either a portion of it should be removed for microscopic examination (this can be done easily and painlessly with a local anæsthetic), or the disease should be considered malignant and freely removed. The teaching which students receive and what they read in their surgical text-books is largely responsible for the failure to diagnose these cases early, as the descriptions

usually given of cancer of the tongue and, indeed, of cancer elsewhere in the body is generally that of a case in an advanced stage, thick everted edges, fixation of the tongue, difficulty in speaking and swallowing, enlargement of glands, cachexia, etc. This is not the stage in which to diagnose cancer, anybody could do this. Your rule should be *never be satisfied unless you have made a definite diagnosis of the presence or absence of malignancy within three weeks of your first seeing the disease*, and if this is within three weeks of its first appearance, so much the better. If this rule were adhered to most cases of cancer of the tongue would be operated on while still small and confined to the tongue, and could be removed from within the mouth without any extensive operation, and one would not meet so many cases which had advanced to the truly appalling stage of the one I showed you this morning. A partial removal would in most cases suffice, the cut edges of the tongue could be stitched together and the inconvenience would be almost unnoticeable, the mortality of the operation would be infinitesimal and the chance of recurrence would be slight.

Lastly, is it advisable to operate in advanced cases where the glandular involvement is considerable? Yes. Some of these cases recover in a marvellous manner and live for many years free from any recurrence. Though the mortality of the operation is high, these patients, if left to themselves, suffer very severely and a fatal result must come, usually rapidly. Even where it is impossible to remove all the glands it is yet advisable to remove the disease in the mouth, as this relieves the patient of most of his pain and discomfort, and allows him to take his food and die at a later date in comparative comfort.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by J. Stewart Fowler, M.D.Ed., F.R.C.P., Physician to the Royal Hospital for Sick Children, Edinburgh. Subject: "Dechlorination in the Treatment of Chronic Bright's Disease."

## ORIGINAL PAPERS.

### QUACKS FALSE REMEDIES AND THE PUBLIC HEALTH.

By DAVID WALSH, M.D.ED.,

Senior Physician, Western Skin Hospital; Physician, Kensington and Fulham General Hospitals.

#### PART II.

#### BLOOD MIXTURES AND PURIFIERS.

THE stock active ingredient in the majority of these so-called purifiers is iodide of potassium, a valuable drug extensively used in medical practice. Its indiscriminate use, however, is attended by certain risks, especially in persons who are specially susceptible to its action. Thus it sometimes sets up a rash on the skin, which, if improperly treated, or if the action of the drug be continued, may lead to serious or even fatal results. Every physician of experience in skin practice knows of eruptions due to taking blood mixtures. In some instances the unhappy sufferer imagines that the medicine is "bringing out" the disease, and goes on increasing the dose. In any event, it is impossible to justify even remotely the extravagant claims of the vendors of these blood mixtures.

Thus, in a reproduction of Clarke's Blood Mixture in the "Australian Report" (p. 165), occur the specific statements:—"Blotches, spots, pimples, blackheads, and sores of all kinds can be cured by taking Clarke's Blood Mixture, the world-famed blood purifier. This famous medicine will also cure all skin and blood diseases, such as eczema, scrofula, scurvy, ulcerated sores, etc." So far as the curative effect of iodide of potassium upon skin diseases is concerned, it may be briefly stated that its curative effect on skin maladies is extremely limited, and that the vast majority of affections of that kind are either unaffected by potas-

sium iodide or are aggravated and made worse by it. From the appended analysis there is no other ingredient in Clarke's Blood Mixture that could conceivably exercise any therapeutic influence over the skin. Under these circumstances, any justification of the statements above quoted from the advertisement would be difficult, or altogether impossible. Indeed, in cases where the well-known "iodide rash" follows the use of a remedy shown to contain iodide of potassium, there should be little difficulty in substantiating a claim for damages on the part of the sufferer.

The composition of the active ingredients of Clarke's Blood Mixture is given by Dr. Robert Hutchison approximately as iodide of potassium (about 6 grains to the ounce) ("Australasian Report," p. 190).

The British Medical Association analysis is:—

Potassium iodide, 52.5 grains.  
Spirit of sal volatile, 10 minims.  
Spirit of chloroform, 67 minims.  
Simple syrup, 50 minims.  
Burnt sugar, q.s.  
Water to 8 fluid ounces.

"The estimated cost of the ingredients is 1½d." (The bottle is sold at 2s. 6d.)

Harvey's Blood Pills, according to the same authority (p. 45, "Secret Remedies") are made up approximately as follows:—

Quinine sulphate, 17 grains.  
Potassium iodide, 22 grains.  
Powdered rhubarb, 16 grains.  
Powdered liquorice, 8 grains.  
Ext. of sarsaparilla, 12 grains.  
Ext. of burdock, 12 grains.  
Ext. of taraxacum, 12 grains.

Divided into 36 pills.

The reproduction of the accompanying circular states:—

"Harvey's Blood Pills for Skin Diseases. An Unfailing Remedy for Scurvy Sores! Harvey's Blood Pills for Scrofulous Sores. A Certain Remedy for Ulcerated Legs! Harvey's Blood Pills for Sluggish Liver. The Surest Remedy for Ringworm! Harvey's Blood Pills for Erysipelas. The Quickest Remedy for Itch! Harvey's Blood Pills for Boils. An Effective Remedy for Eruptions! Harvey's Blood Pills for Rheumatism. The Safest Remedy for Piles."

Of this farrago of nonsense it may be stated that the ingredients shown in the analysis could, neither alone nor combined, exert any curative influence upon ringworm or itch. Any person, therefore, purchasing the pills for the cure of either complaint, and remaining uncured, would have a ground for action for failure of contract. As to the pills being an efficient remedy for eruptions, it need only be stated that the study of skin diseases embraces an immense variety of conditions that demand prolonged study and special training to grasp at all adequately. In many conditions the cure of skin diseases is tedious, and in some hopeless. Moreover, the use of two at least of the ingredients of the pills might create, and possibly aggravate and intensify certain skin eruptions.

It needs little beyond these simple statements to prove that the claims set forth in the above-quoted advertisement are preposterously false. Yet they are issued to the public under the cloak of a Government stamp, which to the ignorant purchaser is a sort of guarantee of the genuineness of the wares thus distinguished. Why should the trade in secret remedies alone be permitted to press and advertise claims that will not stand the test of ordinary commonsense examination as to their genuineness? If a man professes to cure diseases and to sell remedies for that purpose, should he not be called upon to justify his statements and forced to adhere to the terms of the contract entered into with his customer on the direct assertions of his advertisement? Lastly, what is to be said of the editor who admits such an advertisement to his columns?

Dr. Squire Sprigge, Editor of the *Lancet*, has spoken with no uncertain voice on the last mentioned point.

SQUIRE SPRIGGE ON NEWSPAPER AND QUACK ADVERTISEMENTS.

"A newspaper editor," he writes, "or manager may be

pardoned if he thinks that the use of his columns to make a nostrum known is a legitimate branch of newspaper business (a), especially when it is remembered that if he took the opposite view the proprietor of the newspaper might be willing to hear of his resignation. But while this is true with regard to some advertisements, it is not those of others, and the disgusting advertisements of many modern quacks ought to be tolerated by no self-respecting editor, manager, or proprietor. Yet no falsehood is too shameless, no promise too palpable a trap, to be refused currency in the advertisement columns of the best-known journals, and it is noteworthy that among the worst offenders in this respect are newspapers and magazines which enjoy with certain classes of the community a high reputation for accuracy and *bond fides*."

Munyon's Homœopathic Home Remedy Company, an American company with an office in London, sells a cure which claims to eradicate all impurities from the blood, and, amongst other things, "any form of unhealthy, blotchy, pimply, or scaly skin." The British Medical Association found a bottle to contain 200 pellets or pilules, consisting of sugar. No other medication was present. To sell sugar to cure impurities of the blood and scaly skin is a transaction which would, in any other branch of trade, be stigmatised by Anglo-Saxon terms of a simple and direct kind. Would the British Government, which permits America to dump this sort of rubbish on our shores, permit sugar to be sold for the cure of the ailments of sheep, cattle, or pigs? Any member who asked such a question in the House of Commons would become an object of ridicule. Yet sugar may be sold under the shield of a Government stamp for the cure of diseases in men, women, and children. A more absurd position it would puzzle the caustic wit of Swift or of Voltaire to devise.

A Blood Purifier sold by "Professor" O. Phelps Brown was found by the same authority to contain 15 per cent. of sugar, a good deal of mucilage, 25 per cent. of alcohol by volume, and of vegetable and other substances difficult to identify, but of little or no therapeutic value. Yet this secret remedy is advertised as "an infallible remedy for all diseases of the blood, be they constitutional, hereditary, or of recent contraction." It further states that "ulcers, tumours, scrofula bunches, fistula, piles, painful eruptions—indeed, all affections manifested upon the outer surface of the body are the consequences of diseased blood." From the medical point of view this is nonsense that is beneath contempt, but it becomes pernicious and harmful when it is advertised with the object of inducing the public to purchase a worthless nostrum. That the Government stamp should be affixed to claims of this kind is a standing disgrace to our nation.

#### CURE-ALLS.

The above heading was aptly framed by the British Medical Association to include proprietary medicines claiming to cure a wide range of maladies. Dr. Williams' Pink Pills for Pale People may be taken as an example. The following extract from an advertisement is quoted in the Association book (p. 174):—

"THE DR. WILLIAMS' WAY.

"When the muscles and nerves are tortured by poisons in the blood as the result of rheumatism, sciatica, or lumbago, the only way to a cure is to enrich and purify the blood. Dr. Williams' Pink Pills, in this way alone, have cured not only rheumatism, but anæmia, indigestion, palpitations, influenza's after-effects, eczema, sciatica, St. Vitus' dance, spinal weakness, the many forms of nervous disorders dreaded by men; also the special ailments of women."

The drug that effects these marvels is shown by the British Medical Association analysis to be "practically the ordinary iron-carbonate commonly called Bland's pill, which ought to be freshly made." The pills are sold at 2s. 6d. per box of 30, or a penny apiece, whereas Bland's can be bought wholesale for about 1s. or 1s. 3d. per gross, or in bulk at a much lower price.

(2) "Medicine and the Public," p. 71.

The Pink Pills were originally made by George Taylor Fulford, a small country chemist in Ontario, Canada. The "Australian Report" (p. 199) says that Charles Fulford, nephew and Australian representative, admitted upon oath in a Melbourne court, "There is no such person as Dr. Williams." Paragraph 741 states that Fulford became a Senator of Canada, died in the odour of sanctity, received a public funeral, and left five millions of dollars." "This fortune was amassed by selling a well-known cheap and ordinary drug under a fictitious name at scores of times its actual money value by means of claims absolutely unsupportable." The Pink Pills may be dismissed with the simple addition of the Australian official comment (§740):—"New blood can be made from foods only, and not from arsenic, potash, or sulphate or carbonate of iron. The business is plunder from first to last, mendacity, audacity, and altogether heartless exploitation of the poor and suffering, with the indispensable assistance of newspapers."

The genius of the Fulford family evolved two other patent medicines that have gained enormous publicity, namely, Zam-buk and Bile Beans.

In the Court of Session, Edinburgh, July 20th, 1906, an action was brought by the proprietors of Bile Beans to prevent a chemist from selling, under the name of "Bile Beans," any pills not supplied by the complainers.

"Lord Ardwell, in the Outer House, had refused the note, and found the respondent entitled to expenses, on the ground that the business of the petitioners was one founded entirely upon fraud, impudence, and advertisement" ("Australian Report," p. 195, § 725).

The Lord Justice Clerk, who delivered judgment, spoke in terms perhaps as deliberately scathing as any ever used in a British Court of Law. (a) "The evidence in this case," he said, "discloses the history of a gigantic and too successful fraud. The two complainers, who ask an interdict against others, do so to protect a business which they have brought to enormous proportions by a course of lying which has been persisted in for years. The scheme they formed was to delude the public into the belief that a valuable discovery had been made of a medical remedy hitherto known only to certain savage tribes in a distant part of the world, but known to them for ages, and that the medicine had been prepared by the aid of 'the implements of modern scientific research,' and that the best laboratories and the most modern plant had been requisitioned for compounding the wonderful Australian vegetable substance. The place of the discovery, the mode of discovery, the discovery itself, the instruments of research, the laboratories, were all deliberate inventions, without any foundation in fact. The story was that a certain Charles Forde, who was declared to be a skilled scientist, had, while in Australia, noted the fact that the Aborigines were markedly free from certain bodily ailments, and that, by patient research and exhaustive investigation, he had ascertained that this immunity was obtained by the use of a natural vegetable substance whose properties for cure of such ailments was extraordinary, and that, as the result of his research, this wonderful remedy was now given to the world. All this was in every particular undiluted falsehood. There was no such person as Charles Forde; no eminent scientist had been engaged in researches; no one had gone to Australia and learned of a time-proved native cure. The truth was that the complainers had formed a scheme to palm off upon the public a medicine obtained from drug manufacturers in America as being the embodiment of the imaginary Australian eminent scientist, Charles Forde. Accordingly, having got their supplies from the American drug dealer, they proceeded to create a public demand by flooding this country and other countries with advertisements in the Press, and by placards, and leaflets, and pamphlets, in which the lying tale was repeated, often embellished with pictorial advertisements of the healthy savage, and with pictures of the imaginary scientist, duly bearded and begoggled, having the precious root pointed out to him by the Australian native. It was of importance in exploiting a fraud of this kind to get a catching name, and the only trace of discovery in the whole proceed-

ings was that the complainer Fulford thought out the alliterative name of Bile Beans for Biliousness. . . . I agree with the Lord Ordinary in holding that the complainers being engaged in perpetrating a deliberate fraud upon the public in describing and selling an article as being what it is not, cannot be listened to when they apply to a Court of Justice for protection. It is their own case, as brought out in evidence, which stamps their whole business with falsity."

Zam-buk may be dismissed shortly. It is an ointment which claims to be "unequalled" in fifty or sixty widely different ailments. Amongst them are itch and ringworm, but if the composition of the ointment be that found by the analyst of the British Medical Association, it could not conceivably cure either affection. The British Medical Association publishes the following analysis (a):—

Oil of eucalyptine, 14 per cent. (approximately).

Pale resin (colophony), 20 per cent. (approximately).

Soft paraffin, 55 per cent. (approximately).

Hard paraffin, 11 per cent. (approximately).

Green colouring matter, a trace.

A vast number of secret remedies remain, but enough has been said to illustrate the main conclusions that the claims made for these preparations are in most cases extravagant, and directly opposed to medical knowledge and experience. Further facts regarding them can be found in profusion in the books which have been so frequently quoted. At the same time it may be useful to discuss briefly the outstanding features of certain groups of these secret remedies.

#### CONSUMPTION CURES.

There is no specific drug cure of consumption, a scientific fact that alone disposes of the many cures which are sold for the cure of that disease. Certainly none of the drugs contained in the various British Medical Association analyses could have any such effect. In the case of some of the emulsions sold by respectable firms under a proprietary name, some of them are undoubtedly useful in the treatment of consumption. If the proprietors were content with that statement, there could be little objection to the sale of their preparations without appended formula. When, however, they go beyond that, and claim to cure consumption by the use of their emulsion, their claim at once becomes unsupportable, and they are selling their wares under misrepresentations that are misleading to the public. Some of the "cures" for which high prices were charged have been shown to depend on ipecacuanha, opium, glycerine, krameria, bromide of potassium, and other substances that could not by any possibility bring about any such effect. Several of them contain 20 to 25 per cent. of alcohol—that is to say, the medicine consists of a stiff dose of spirits and water, which doubtless helps the unfortunate consumptive who takes it to feel a little better while under its stimulating influence. In discussing this class of remedies, the "Australian Report" (p. 157, § 586) quotes the following pithy comments from the *Sydney Bulletin*, February 28th, 1907, upon a contemporary trial, in which the defendant was acquitted upon the ground that "he probably believed—at least, there was no possibility of proving that he did not believe—the statements that he issued about" the secret remedy concerned. The *Bulletin*, brushing aside all legal cobwebs, says of this:—"Only an utterly heartless wretch would delude miserable and often impoverished consumptives into spending pounds on alleged remedies unless he knew, as a matter of expert personal knowledge, that the article he sold was specific. A plea that he had never received any medical training, and so was only taking the money of the consumptives at random, should be good in itself for a long term of gaol."

It has been known that the names and addresses of persons who apply to advertisers of unqualified treatment and of secret remedies are hawked about as a valuable stock-in-trade. That fact was alluded to several times in the "Australian Report," and in one case a chemist reported his indignant rejection of the suggestion by an advertising firm that he should disclose to them the names of any of his clients whom he knew to be suffering from diabetes.

(a) "Australian Report," §726.

(a) "Secret Remedies," p. 122.

## FEMALE COMPLAINTS.

Under pretence of providing remedies for female irregularities, all kinds of dangerous drugs are administered. There can be no doubt that an abortifacient action is suggested in many of these advertisements. Such a result is not obtainable by drugs except by chance action, and then only by the injury of the health of the unfortunate woman who takes them to such an extent that she runs a risk of death. When death follows, its cause is probably, as a rule, unsuspected. Women who apply to advertisers of this kind run the risk of subsequent blackmailing. In one case not many years ago in London, extensive blackmailing of that kind was discovered by the police. Although the more respectable newspapers have been purged of this particularly obnoxious class of advertisement, they are inserted to a disgraceful extent in smaller journals, perhaps more especially in a certain type of Sunday newspaper, and, sad to say, in the religious journals, which, for some reason or other, have always been a favourite medium for gross quackery of every description.

Whatever views the Home Office and the police may take with regard to the desirability of interference with ordinary trade in secret remedies, there can surely be little difficulty with regard to the veiled solicitation of the class of advertisement under notice. No man of the world with a fair general experience of affairs would be in a moment's doubt as to the inner meaning of an advertisement of the kind. As newspaper editors, police inspectors, and leading political administrators are necessarily men of the world, with large experience of social affairs, it follows they know the nature of such documents. What defence, then, can there be for editors who admit such matter to their columns, or for police or Home Office authorities that permit the public morality to be outraged by such publication?

## REMEDIES FOR EPILEPSY, FITS, AND NERVOUS DISORDERS.

A flourishing trade is done in the sale of bromide of potassium for the cure of epilepsy. As a matter of fact, the drug in question does not cure that malady, nor, indeed, is any specific cure known to scientific medicine. Bromide of potassium, however, is used by medical men generally to control the malady. There is no special virtue in the solutions sold by the proprietary medicine vendors, while they charge extravagant prices—say, as much as twenty or thirty times the cost of the ingredients. In the few cases in which bromides are not used, the substituted drugs revealed by analysis are not such as would exercise any beneficial effect upon epilepsy.

## CURES FOR INEBRIETY.

This class of cure furnishes a lucrative field to the adventurer. A favourite plan is to sell a powerful narcotic, whereby one craving is substituted for another—acetanilide, bromide of potassium, atropine, and other powerful alkaloids. Many persons addicted to drink can abstain for a time at will, and improve under the mere abstinence which is a feature in nearly all drink cures. It is impossible, therefore, to accept the assertion that persons have been cured thereby. Moreover, a prolonged period of time must elapse for the establishment of an actual "cure." In one case that came under the author's notice, a patient and his friends congratulated themselves upon the good results of a notorious American method of treatment. Their glowing thanks were no doubt carefully enrolled amongst the firm's testimonials. For all that, the unfortunate patient died a year or two later from the effects of drink.

## CANCER REMEDIES.

At the present moment the utmost resources of medical science are concentrated upon the investigation of cancer. In spite of the enormous mass of skilled labour that has been brought to bear upon this subject, the cause and the medicinal cure of cancer are alike unknown. The only hope to the sufferer lies in the early recognition of the disease by a skilled medical investigation, and its early and complete removal by the surgeon. In the face of this dispassionate statement, it is clear that secret remedies which delay

medical advice and surgical operation simply deprive the unfortunate sufferer from cancer of his only chance of recovery. More than that, analysis shows the remedies thus given internally to be inert or worthless. In the case of a famous foreign quack years ago, analysis showed his electrical fluids of various colours to be water, pure and simple. When the remedy is for external application, the case is infinitely worse, for the sufferer is often put to extreme and long-continued agony by the use of caustics that cannot cure. By the use of modern methods the last days of the unfortunate sufferer from malignant disease can be robbed of a great amount of suffering, but in the hands of the quack the elements of pain and of septic poisoning, with its harrowing accompaniments, run their dire course unchecked. Yet colliers, ploughmen, herbalists, and others are permitted by law to carry on the terrible trade of "cancer-curing" without let or hindrance. Of what standard is the collective wisdom of a State that permits cruelties of this kind to be inflicted upon her weak and credulous citizens that she would not for a moment allow to be practised upon her pigs or cattle? A man who pretends to treat dogs without a veterinary qualification is instantly prosecuted and fined by the authorities, but there is nothing to prevent him making a good thing by transferring his attention to his fellow-creatures. If he has a good address and can start in a fashionable quarter of a big town, his success would be assured.

## OTHER CURES.

The cures for deafness cover a large field of enterprise. They are usually obtained direct from the nostrum vendor, and consist of glycerine and other ingredients that could not exercise any beneficial influence upon nerve deafness. As a rule they are sold in connection with some mechanical appliance.

Another class of injurious remedies are those sold for eye diseases. Thus, Singleton's Eye Ointment (a) is advertised as "an absolute specific for all eye troubles and diseases." The same authority gives its chief ingredient to be red mercuric oxide, a drug recognised and used by ophthalmic surgeons, but absolutely unfitted for a vast number of the many maladies to which the human eye is subject. In some affections of the kind instant skilled treatment is necessary in order to prevent irreparable injury to the sight, and it is painful to reflect how much injury is inflicted upon the community who resort to the indiscriminate use of advertised remedies.

Remedies for blindness form another class of heartless and injurious secret remedies. Needless to say, blindness is the result of conditions that, in the vast majority of cases, cannot be benefited by drugs, whether internally or externally administered. When an unskilled person advertises his power to cure blindness, he should surely be held legally responsible for advancing that claim. The ignorance of the facts of the case involved in so preposterous a claim furnishes in itself damning proof of his incompetence.

(To be continued.)

## THE ADDENDUM PRANDII AND PROFESSIONAL EDUCATION. (b)

By J. SIM WALLACE, D.Sc., M.D., L.D.S.

MOST of us must often have wondered why it is that so many members of the medical profession seem to take so little interest in the hygiene of the mouth. For the mouth is admittedly the great entrance-portal of disease. The natural self-cleansing processes of the mouth are, as a rule, unknown to them, and, instead of aiding these self-cleansing processes, they very frequently advocate procedures which would really appear to have been deliberately invented to ruin the physiological perfection of the mouth at the earliest possible age. We, of course, as dentists, see what actually takes place, and are painfully aware of the havoc wrought in children's mouths and teeth at

(a) See "Secret Remedies," p. 142.

(b) Paper read before the Annual General Meeting of the British Dental Association at Birmingham, 1909.

or even before the age of six. It has been shown that in some towns in England where accurate statistics have been taken each child has on the average about nine carious teeth at this age. It is not possible to say that this results from disobeying the dictates of the medical profession, for it is common knowledge that children brought up most carefully according to the *régime* advocated by the highest authorities in the medical profession have their teeth equally carious, as a rule, at an even earlier age than those children who have but little care bestowed upon them and who are allowed to do and eat pretty much what they like. Is it not enough to recognise that the system currently advocated will eventuate in the destruction of the teeth, and then blame fate or the depravity of the human constitution? Nor is it sufficient to advocate that children should be taken to the dentist every six months. This latter is obviously necessary, and will always remain a wise precaution, however much things are improved; but it should be distinctly realised that teeth do not decay except when the dietetic *régime* has brought the mouth into an unhygienic state, and it should also be recognised that this unhygienic *régime* should be rectified immediately the dental surgeon has rendered the teeth functional and the mouth potentially self-cleansing, for an unhygienic *régime* is not only a menace to the teeth, but to the child's health in general.

There has of late been an enormous amount of investigation on the subject of the nutritive value of foods. This is, of course, an important subject, at least to those who are on the verge of starvation; but to those who have enough to eat the more important question is: is the food hygienic? is it such as is conducive to health? The nutritive value of a pound of putrid meat may be about as much as the nutritive value of a pound of fresh meat, from a chemical point of view; but from the hygienic point of view it may have a totally different value. So, too, the value of food which lodges and ferments in the mouth is quite different from food which is digested in the stomach. It is with regard to the hygienic value of certain articles of diet that I intend to speak, because the nutritive value of the food has practically nothing to do with caries of the teeth.

Now it is obvious that the hygienic state of the mouth, in so far as it depends upon foods, depends more especially on what is taken towards the end of the meal, for it is the food that remains or lodges in the mouth after the meal is over which ferments and causes the disastrous results to the teeth. It is not a matter of indifference, therefore, whether a meal be finished with food which leaves the mouth clean or leaves it dirty. And, overlooked though it may have been, some foods do leave the mouth clean and some leave the mouth dirty, or, rather, do not leave it at all until they have undergone fermentation or putrefaction in the mouth. This is a simple, obvious, and important point, and has helped to give rise to a characteristically civilised custom, the custom of having arrangement in the meal. Recent investigations in the physiology of digestion have shown the wisdom of arrangement of the meal as far as digestion is concerned, and it is my intention to show how the further arrangement of the meal which custom prescribes, but which is not yet countenanced by physiologists, is eminently the result of the hygienic requirements of the mouth. We may here refer to the present state of knowledge in the medical profession. In an article on "Post-Prandial Habits" in the *Lancet* (a) last year, the following observations were made:—"As a rule, post-prandial habits do not receive the approval of physiological teaching. Theoretically they are calculated to interfere, and often in practice their indulgence does interfere, with the healthy disposal of the meal. From a purely physiological point of view, at all events, the post-prandial habits are superfluous. . . . Post-prandial habits, in short, have their origin in the fact that they are a source of enjoyment, and enjoyment is the chief excuse for their indulgence. . . . To the man who thus, as it is said, 'does himself well,' these things are regarded as the crowning attraction of a good dinner. They are, of course, nothing

more than easily acquired habits which, though associated with the meal, have really nothing to do with it regarded as a nutritious mass."

Professor Pawlow, after showing how the ordinary arrangement of the meal is justified physiologically, says:—"The usual termination of the repast is also from a physiological standpoint easy to understand. The chief meal is generally ended with something sweet, and everybody knows that sweets are pleasant." (a)

These extracts indicate the views of medical men and physiologists at the present day; and it will be observed the hygiene of the mouth is completely overlooked. It is quite true that sweets are pleasant, but it is not true that in a well-regulated repast the chief meal ends with sweets. Dessert or fresh fruit always does or should follow sweets, because sweets leave the mouth sticking with fermentable carbohydrates, and, moreover, give the mouth a clammy feeling which anyone who is accustomed to having the mouth physiologically clean has a difficulty in tolerating. There are two customs which have arisen, no doubt on account of the dirty feeling which results from refined, civilised, and more especially sweet foods. They have both originated independent of scientific teaching. One is the brushing of the teeth after meals. This is frequently done by some savage tribes, and sometimes done by the civilised. The other custom which has arisen among the more highly civilised is what we may call the *addendum prandii*, or the eating and drinking of foods which clean the mouth at the end of the meal.

The question naturally arises how far this latter custom, which has arisen more or less instinctively, is in accord with the hygienic requirements of the mouth. We know that there are three important processes which in a natural way keep the mouth in a hygienic state. These may be referred to as—(1) the mechanical, (2) the chemico-physiological, and (3) the parasitic or saprophytic processes. We know that the mouth is left in an exceedingly unhygienic state after a meal, or rather after a "nutritious mass" ending with sweets has been consumed. We must now ask if the usual additions to the nutritious mass are useful in washing away such carbohydrates or sweets as are left in the crevices and inaccessible interspaces of the teeth, which even a toothbrush cannot be made to clean out properly. I have already said that a well-regulated or hygienic repast does not end with sweets, but that the sweets are properly followed by something of a detergent nature. Firstly, let us direct attention to fresh fruit, which customarily follows sweets. We need not refer to any nutrition which may be found in fruit. This is little in amount, and unimportant from the point of view of cleanliness. Fruits, however, invariably contain cellulose in its natural state—that is to say, it is of a somewhat fibrous consistency, which, when taken into the mouth, stimulates a pleasurable amount of mastication. This is, of course, an important stimulus to the mechanical self-cleansing of the mouth. Then the fibrillar meshwork of the fruit contains the vegetable acids, the sweet juices, and the aromatic essences which render the fruits so palatable. Now when by the act of mastication these various delectable liquids are expressed from the fibrillar mass, the gustatory nerves are stimulated, the mouth is flushed with saliva; in other words, the chemico-physiological self-cleansing processes are stimulated. This, coming at the end of the meal, when the appetite has ceased to be keen and the relish for a nutritious mass is at an end, is highly important. But this is not all. The sweet and aromatic flavours remain in the mouth even after the diluted sugars have been expressed and swallowed, and thus prolong the chemico-physiological self-cleansing processes. The fibrillar part of the fruit which is swallowed last is meanwhile mopping up the particles which have been left about the crevices of the teeth, to be expressed and swallowed after further mastication. Fortunately, too, the aromatic flavours, the vegetable acids and essential oils in the fruits, leave a taste in the mouth, giving it a clean and fresh feeling which is but moderately imitated by some of our best mouth

(a) *Lancet*, Nov. 7th, 1908.

(a) Pawlow. "The Work of the Digestive Glands," p. 140.

washes, so that after the mastication of fibrous foods which so dexterously clean the crevices of the teeth there is a flow of saliva which as a further precaution seems to perform the finishing touches of the dental toilet. So much for the mechanical and physiological processes. We must just note again quite briefly the effect of fruit on the bacterial or saprophytic process. All fruits are acid, and, as Dr. Miller has shown, "Acids and alkalies, especially the former, even in very dilute solution, retard the development of bacteria." (a) Furthermore, "the growth and ferment activity of bacteria are always more or less influenced by their own waste products." (b) "The bacteria themselves are often destroyed by the action of the acid which they have produced," it therefore follows that the acid forming bacteria more especially are retarded in their growth or destroyed by the acids in fruits, while the alkali-forming bacteria are not correspondingly affected. (c)

Now let us briefly refer to the liquids which sometimes form the whole or more generally part of the *addendum prandii*. The liquid most generally consumed after a meal is coffee. This is generally recognised as a pleasant way of terminating the meal. A cup of coffee after a meal is generally slowly consumed, each mouthful washes away some of the food particles which may be lodging about the teeth, and the aromatic flavour stimulates the salivary secretions, which help to clean the mouth. If the meal has not been of a particularly sticky character, and if the teeth are normally arranged a cup of coffee may be sufficient to make the mouth physiologically clean.

It may be said that post-prandial liquids such as I have referred to have certain disadvantages. We may be told that a cup of coffee impedes digestion. Perhaps it may. But what of that? Does it necessarily follow that those who swallow their food quickest digest it best? Does it necessarily follow that within limits there is any advantage in rapid digestion in the stomach? Should we always eschew roast beef and potatoes because they take longer to digest than boiled mutton and boiled rice? I scarcely think we should, and, like other men, we will have our cup of coffee after dinner, or after any other meal at which we fancy it. Perhaps we shall have more, we may also have a fairly good hygienic reason for having it. We may take up another line of argument and claim that though coffee does retard the digestion of proteids in the stomach, it promotes the digestion of the carbohydrates by allowing alkaline digestion of the carbohydrates to be prolonged, for inasmuch as coffee is taken last and stimulates the secretion of saliva, and in so far as it mixes with the carbohydrates taken at the end of the meal, it rather aids their digestion; while the proteid digestion at the pyloric end of the stomach is unimpeded. I presume you are all aware that the supposed churning motions of the stomach are now regarded as somewhat mythical, and that for an hour or two after a meal the stomach tends to keep the food in the position in which it was introduced, although it has the power of expelling water.

We do not need to pursue this subject further at present. Enough has been said to indicate either that we know nothing about the hygiene of the mouth, or that the medical profession knows nothing or cares nothing about it. Simple methods of dental hygiene, such as the toothbrush and mouth washes, seem now to be quite inadequate to prevent the ruinous results of a dietetic system such as is being forced upon the children of the present generation with the most dogmatic assurance. Hardly has a child cut its temporary teeth before it is *restricted* to soft, fermentable foods, which stultify the natural self-cleansing processes of the mouth. Young children are almost entirely limited to milk, bread soaked in milk, milk puddings and porridge, all fermentable

foods which are non-detergent in their effects, and by the time these children have their temporary dentition complete the teeth are so tender from lack of use they naturally refuse to nibble even a crust. What can we do? We are dentists, and as it is supposed that the dietetic *régime* should be left to the medical profession it does not seem likely that we shall be able to do much without the co-operation of medical men. And when we have the great authorities paying all their attention to the nutritive value of the food it is difficult to persuade anyone that lack of oral hygiene accounts for far more trouble among children than lack of nourishment. Children are supplied with ample nourishment, except when depravity has destroyed all parental instincts. The difficulty which parents sometimes find in getting their children to take enough food results, in most cases, from the insanitary state of the mouth and alimentary canal, and it cannot astonish us that children refuse the nourishment which has brought about this insanitary state. Unfortunately the medical student is generally devoid of elementary knowledge with regard to the teeth, oral hygiene or preventive dentistry. A medical student never learns anything about the diseases of the teeth, because he knows that medical students are never examined in these subjects at their examinations. Why should this be? A man should not be a general practitioner if he is grossly ignorant of any important part of the body, much less should he be regarded as duly qualified if he knows nothing about the hygiene of the entrance portal of disease. A State which recognises any such man as qualified to practise medicine does not recognise the value of preventive medicine much less of preventive dentistry. Universities which turn out such men are doing a serious injury to themselves and to the public.

## THE TREATMENT OF RHEUMATOID ARTHRITIS.

By ALBERT ROBIN, M.D.,

Professor of Clinical Therapeutics, Physician to the Beaujon Hospital, Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

POLYARTHRITIS DEFORMANS, or rheumatoid arthritis, is a disease of nutrition which comprises several pathological factors. In the majority of such patients there is a history of some previous infection and gastric fermentation with retention of toxins.

Of seven patients suffering from this disease in my wards all suffered from gastro-intestinal fermentation with a diminution of nitrogenous metabolism and an increase in the coefficient of urinary toxicity. The coefficient of urinary toxicity is based on the relationship between the incompletely oxidised nitrogen (toxic) to the total nitrogen. Normally the relationship is from 13 to 15, but in these patients it reached 17.

The phenomena of rheumatoid arthritis comprise a process of osteoporosis which culminates in rarefaction and ultimate decalcification of the bones. The urine contains an abnormal proportion of earthy phosphates, lime and magnesia. The urinary chlorine is in excess, and the indican and ethereal sulphates are increased, testifying to the existence of putrefactive fermentations in the intestine. Examination of the blood reveals a slight diminution in the proportion of hæmoglobin, in fact there is a state of toxin-æmia.

These data indicate the treatment. Hitherto this has been purely empirical, and therefore uncertain, in its results. Innumerable treatments have been tried, most of them without any measure of success.

An exception must be made in favour of tincture of iodine. Recommended by Lasègue and Trouseau, it affords marked relief of the pain, provided it be given in sufficiently large doses (m. x to xx.

(a) "Micro-organisms of the Human Mouth," p. 12.

(b) *Ibid.*, p. 14.

(c) When we recognise the nature of the self-cleansing processes of the mouth it is obvious that some fruits may not stimulate these processes so well as others. It is possible too, that there may be an exception or exceptions to the rule. Grapes, for example, contain a large amount of fermentable sugar—and presuming, of course, that the skin is not eaten—very little cellulose such as would stimulate mastication.

of the Codex tincture daily). Unfortunately, this treatment often gives rise to gastric disturbances which render its continuance impossible.

Arsenate of soda is sometimes given, and Guéneau de Mussy used to prescribe arsenical baths containing two drachms of arseniate of soda and five ounces of bicarbonate of soda, the latter being omitted in cases of rheumatism associated with much pain or accompanied by a rise of temperature. The bath is taken at a temperature of 95° F., and the patient remains therein three-quarters of an hour. When the patient complained of pain on leaving the bath he prescribed eight grains of Dover's powder.

Few drugs are of much benefit—salicylate of soda, aspirine, carbonate of guaiacol, iodide of potassium, trinitrine, etc. Iron, cod-liver oil and arsenic improve the general health, but do not influence the local lesions.

Local treatment is more efficacious. Hot baths, mud baths or hot sand baths assuage the pain far better than Bier's method, the effects of which have been much overrated.

We need only mention Shuller's treatment, which consists of injecting a mixture of iodoform, glycerine and guaiacol into the damaged joints. It is very painful, and yields very uncertain results.

The practitioner will be better advised in having recourse to various methods of treatment which fulfil the therapeutical indications when associated with a suitable regimen.

I have already called attention to the constant presence of gastro-intestinal fermentation in these cases. This may be checked by a rigid dietary and the administration of antiseptics which, while arresting the proliferation of the figured elements, do not interfere with the action of the soluble ferments. In presence of lactic fermentation we may order:—

Ammonii fluoridi, 3 gr.  
Aquæ dest., 10 fl. oz.

A tablespoonful to be taken during lunch and dinner.

For butyric fermentation:—

Bismuth et cinchonidin iodid (erythrol),  $\frac{1}{2}$  gr.

Calcii carbonatis, 4 gr.

For one cachet. One to be taken with meals.

Should there be hyperchlorhydria, the patient must be allowed no meat, and if farinaceous articles are ill-digested we may give maltine, with keratinised pancreatin pills. We may also reduce the secretion of hydrochloric acid by means of the phosphates:—

Sodii bicarb., 2 dr.  
Sodii phosph., 1 dr.  
Sodii sulph.,  $\frac{1}{2}$  dr.

For one powder. One to be dissolved in a quart of boiled water and a wineglassful taken on rising, at 11 a.m., 4.30 p.m. and 9.30 p.m.

The phosphate of soda contained in this preparation facilitates the assimilation of fats, and is a general stimulant of nutrition, in fact a nerve tonic.

The patient should take a neutralising powder (prepared chalk, hydrated magnesia and bicarbonate of soda) after the meals, at the same time reducing the proportion of salt taken with food. It is well to take a cupful of some hot vegetable infusion after each meal—weak tea, camomile, etc.

This regimen, which has for object to restore the digestive functions, should be persevered with for about three weeks, after which we may have recourse to stimulating medication.

Twice a week the flying cautery should be

applied down the vertebral column. The drugs most likely to prove beneficial are strychnine, the hypophosphites, phosphide of zinc, and the glycerophosphates. These may be combined or given alternately every week or two.

1. *Strychnine*.—From six to eight drops of the tincture of nux vomica in a little water, or a tablespoonful of the following mixture, ten minutes before meals:—

Strychninæ sulphatis,  $\frac{1}{2}$  gr.  
Aquæ, 10 fl. oz.

2. *Hypophosphites*.—These products exert a selective action on the nutrition of the bones:—

Calcii hypophosph.	} aa 1 gr.
Sodii hypophosph.	
Potassii hypophosph.	
Magnesii hypophosph.	
Quininæ ferri hypophosph., $\frac{1}{2}$ gr.	
Strychninæ hypophosph., 1-25 gr.	
Sodii arseniat., 1-50 gr.	
Tinct. rhei. co., 10 m.	
Aquæ dest., 4 dr.	

The draught to be taken with each meal. Multiply the doses by 12 for a six-ounce mixture.

3. *Phosphides*.—Phosphide of zinc is given in pill form, in sixth-of-a-grain doses.

4. *Glycerophosphates*.—These may be given hypodermically (4 gr. of the soda salt) or as a mixture:—

Calcii glycerophosphatis, 14 gr.	} aa 45 gr.
Sodii glycerophosphatis	
Magnesii glycerophosphatis	
Potassii glycerophosphatis	
Tinct. nucis. vom., 8 m.	
Pepsin porci, $\frac{1}{2}$ dr.	
Maltine, 15 gr.	
Extract kolæ, 55-85 gr.	
Syr. prun. virg., 3 dr.	
Aquæ dest., ad 8 oz.	

A tablespoonful three times a day, in the middle of lunch and dinner.

This may be taken for a month, when we may proceed to order iodide of potassium, with or without arsenic, in lieu of tincture of iodine, though without reckoning too much on its efficacy.

Potassii iodid, 75 gr.  
Sodii arseniat., 1 gr.  
Aquæ dest., ad 10 oz.

A tablespoonful twice a day.

*Local treatment*.—In order to stimulate the nutrition of the bones and combat the atrophy of the muscles, the patient should be massaged daily, light "effleurage," after a bath of sulphur water lasting half-an-hour. This bath may be prepared as follows:—

Sodii monosulph., 10 dr.  
Sodii chlorid., 4 oz.  
Sodii subcarb., 4 oz.  
Gelatini, 2 oz.

Or a bag of bran.

Mild, active and passive movements should be practised morning and evening. We may inject metallic ferments in the neighbourhood of the damaged joints in order to stimulate their nutrition.

Electricity is employed in various ways. The Faradic current to prevent muscular atrophy, the Galvanic current for the pain. The positive pole is applied over the diseased joint and the negative pole over the gluteal region. Each sitting should last from a quarter to half-an-hour.

Electro-ionisation has a future before it in this connection, and has already given very encouraging results. Local and general hot air baths afford great relief.

## ABSTRACTS OF PAPERS READ AT THE BUDAPEST INTERNATIONAL MEDICAL CONGRESS.

### A CONTRIBUTION TOWARDS THE DIAGNOSIS OF LARYNCEAL CANCER.

By SIR FELIX SEMON, K.C.V.O., M.D.,  
F.R.C.P. LOND.,

Physician Extraordinary to H.M. the King.

THE author related, and graphically illustrated, those cases of malignant disease from his own practice, in which exceptional diagnostic difficulties were encountered, and in a number of which diagnostic mistakes were made. They amount to 13 in a total number of 246 cases of malignant disease seen in 33 years' practice, and the author, after faithfully recording the salient features of each of them exhorted, in conclusion his younger *confères* not to consider the early diagnosis of malignant disease of the larynx as exceedingly difficult, but to keep in mind such unusual features as are present in the following series of cases now brought forward:—

1. Malignant disease of the larynx, appearing first in the form of a curious tumefaction of the left vocal cord, which remained stationary for nearly two years before showing its true nature.
2. Chronic infective inflammation, simulating malignant disease of the larynx.
3. Extravasation of blood into the right vocal cord and below it, simulating malignant disease of the larynx.
4. Laryngeal tuberculosis in which the laryngoscopic appearances left the diagnosis between malignant disease and tuberculosis quite undecided.
5. Laryngeal tuberculosis simulating malignant disease in an old gentleman, æt. 70.
6. Tuberculous tumour, simulating malignant disease, in the anterior commissure of the vocal cords.
7. Leucoma of a vocal cord, simulating malignant disease of the larynx.
8. Epithelioma of the left ventricle of Morgagni, at first mistaken for papilloma.
9. Epithelioma originating in the form of an angioma.
10. Papilloma, occupying the whole posterior part of the right vocal cord and the inner aspect of the right arytaenoid cartilage in a gentleman, æt. 60, mistaken for malignant disease of the larynx.
11. Epithelioma of the larynx appearing in the form of snow-white, sharply pointed meadow.
12. Granuloma originating in the scar due to removal of an epitheliomatous tumour of the right vocal cord.
13. Inflamed papilloma in a gentleman, æt. 60, closely simulating the appearance of an epithelioma of the larynx.

### CHRONIC FORMS OF PANCREATITIS.

By A. W. MAYO ROBSON, F.R.C.S.,

Emeritus Professor of Surgery, University of Leeds.

MR. MAYO ROBSON drew attention to chronic pancreatitis as a clinical entity apart from gall-stone trouble, and he also described how frequently inflammatory enlargement of the pancreas accompanies cholelithiasis, especially if the concretions are in the common duct. He pointed out that chronic pancreatitis may persist long after the original cause has disappeared, and may simulate cancer of the head of the pancreas, and so terminate fatally under the impression that it is incurable, when, as a matter of fact, suitable surgical treatment is capable of curing the condition. His observations were based on a large series of cases on which he had operated, the first operation having been performed by him in June, 1890 (this patient being in good health 14 years later); a second in 1891 and a third in 1892. In the latter case death occurred two days after operation, and

a microscopic examination of the pancreas showed it to be interstitial pancreatitis. In 1895 he operated on two cases which were in good health several years later, and in 1896 on another case which was well some time subsequently. In this year (1896) Professor Riedel published a paper on inflammatory enlargement of the head of the pancreas in which he described two cases of pancreatitis (the first of which was operated on in 1893) associated with malignant disease, and another paper on cases caused by gall-stones. Mr. Mayo Robson described the symptoms, the pathological condition, the causes and the treatment of chronic pancreatitis, and showed that the anatomical variations in the relations of the common bile duct to the pancreas and in the termination of the ducts had an important bearing on the ætiology of the condition. He urged the importance of preventive treatment, such as the removal of gall-stones before they had produced complications, and the treatment of duodenal ulceration by gastro-enterostomy. If after a fair trial of general treatment, not too long continued, the symptoms persist, and the signs of failure in pancreatic digestion and metabolism were manifesting themselves, the question of surgical treatment, he said, ought to be seriously considered, especially when the disease is associated with jaundice. He said that rational treatment should aim at the cause, whether that was gall-stones, pancreatic calculi, duodenal catarrh, duodenal ulcer, alcoholism or syphilis. Even in the absence of obvious removable causes he advocated efficient drainage of the infected bile and pancreatic ducts, either by cholecystotomy or choledochostenterostomy, preferably the latter. His experience had taught him that if the cause can be removed at an early stage an absolute cure is possible; and though complete restoration of the damaged gland, in more advanced cases, cannot always be promised, yet an arrest of the morbid process may be looked for and the remaining portion of the pancreas will be able to carry on the metabolic, even if incompletely, the digestive functions of the gland.

### THE TREATMENT OF PARALYTIC DEFORMITIES IN CHILDREN.

By ROBERT W. LOVETT, M.D.,

Surgeon to the Children's Hospital, Boston.

THE author remarked in opening his address, that the subject of tendon transference in paralytic deformity has been thoroughly discussed and that no routine discussion of the matter was needed. The varieties of paralytic deformity were first discussed. These are seven. 1. Deformity due to simple gravity distortion. 2. Deformity due to adaptive shortening and lengthening of soft parts. 3. Deformity due to the contraction of non-paralysed limbs. 4. Distortion from weight bearing on partly paralysed limbs. 5. Deformity of the trunk due to effort to secure equilibrium. 6. Bony deformity following persistent malposition. 7. Dislocation. The importance of preventing paralytic deformity was next discussed, recognising the fact that deformity is in nearly all cases preventable. The use of supporting apparatus was advocated from an early period for the purpose of preventing malpositions of the paralysed limb. The treatment of paralytic deformity was discussed first, under the head of mechanical treatment, and, secondly, the operative, both supplemented by a third therapeutic measure, the development of the muscles by muscle training, massage, and electricity. The possibilities of mechanical stretching are: (1) The stretching of contracted tissues; (2) the shortening

of lengthened tissues; (3) the influence of growth toward normal by properly-fitting apparatus. In discussing operative treatment, tendon transference was first discussed. The *technique* of the operation was not dwelt on, but conclusions were presented from the operative results at the Children's Hospital, Boston. Causes of operative failure were discussed with the measures by which the results have been improved. Conclusions favourable to the performance of the operation in suitably selected cases were presented. The results of a circular of inquiry sent out to the members of the American Orthopædic Association were then given, the conclusions from this being that the operation is, on the whole, useful, and that periosteal insertion is preferable to insertion of tendon into tendon. The causes of failure were also discussed from this point of view. The developmental treatment was next discussed, and the conclusions presented that the after-treatment is fully as important as the operative. The summary of the paper calls attention to the fact that the treatment of paralytic deformity should consist of a combination of the three methods, and that the operative should not overshadow the others, and that the operation of tendon transplantation in properly-selected cases is to be regarded as a useful and satisfactory one.

## OPERATING THEATRES.

### ST. THOMAS'S HOSPITAL.

**OPERATION FOR VARICOCELE.**—MR. EDRED CORNER operated on a man, æt. 20, who was suffering from a left-sided varicocele. Mr. Corner said that the result of the operation for varicocele, which most commonly leads to disappointment and disability on the part of the patient, was a hydrocele. He then referred to the statistics given on page 208 of his book, "The Diseases of the Male Generative Organs." This distressing complication, he said, occurred in no less than 23 per cent. of the cases examined, causing the patient, if a candidate for any of the Services, to be rejected, he having thus undergone an operation which left him with as great a disability as that for which surgical measures had been resorted to. In order to meet this difficulty, Mr. Corner suggested, and was going to show how to perform, a simple modification of the operation for varicocele, by which the complication he had mentioned could be avoided. The modification, he remarked, consists in the eversion of the tunica vaginalis. This, as he has pointed out in his book, "Operations of General Practice," is the so-called Indian method, first advocated by Lt.-Col. Pratt, I.M.S., and has much to recommend it, particularly for its simplicity and excellent results. Mr. Corner made an incision, one inch and a half long, on the lower part of the abdomen over the left external abdominal ring. The skin and fat were divided, the external pudic vessels ligatured and cut through. The spermatic cord was then drawn up into the wound; the dilated varicose veins of the pampiniform plexus were separated from the vas deferens and from the deferential vessels for a distance of two or three inches. The ends were then clamped and the varicocele excised. By traction on the lower end of the spermatic cord, the testicle was next drawn from the scrotum into the wound. An incision was made into the upper part of the tunica vaginalis just large enough for the testicle to be delivered and the tunica vaginalis everted. The incision was then held open with retractors, and the testicle replaced in the scrotum. The wound was finally closed and dressed with gauze and collodion. Mr. Corner pointed out that formerly it was thought necessary to use a stitch to retain the tunica vaginalis in its everted position; but if care is taken that the hydrocele (if it exists) when dislocated is freed com-

pletely, and that the incision in the upper part of the tunica vaginalis is a little larger than the horizontal diameter of the testicle, the stitch is not necessary. He thought the gauze and collodion dressing had many advantages: the collodion dries and fastens the gauze firmly to the skin; it prevents the patient fouling the wound or exploring it with his fingers; it allows the surgeon to examine the patient freely without fear of infecting the wound; it cannot shift, and it was a very economical dressing.

## CORRESPONDENCE.

### FROM OUR SPECIAL CORRESPONDENTS ABROAD.

#### FRANCE.

Paris, Oct. 3rd, 1909.

#### INFANTILE PARALYSIS.

INFANTILE paralysis, as is well known, if abandoned to itself, terminates in complete atrophy of the affected limb, and deformities such as club-foot, genu valgum, scoliosis, etc., are frequently the result. On the contrary, when treated, although the atrophy may more or less persist, functional troubles are at least reduced to a minimum; the healthy fibres develop and restore to the muscle some of its primary vigour.

This result is particularly well marked where the treatment has been applied at an early date; but even at a later period considerable improvement may be obtained.

Three periods, says Dr. Weil, mark the development of infantile paralysis: acute, stationary, and the period of irreducible deformities.

The treatment of the acute period consists in warm baths to calm the agitation and lower the temperature, and revulsion over the spinal column.

As soon as the acute stage is over, energetic treatment having in view, on the one hand, to raise the tone of the general condition, and on the other to cure the local lesions, should be instituted. This treatment should combine several therapeutic methods, but a large place should be reserved to one or other forms of electricity (galvanic or faradic).

The general treatment comprises tonics (iron, phosphates), salt water baths, stimulating frictions, sea or mountain air. The local treatment consists in an association of electro-therapy, massage, passive movements, and re-education of the limb.

Each *stance* of electricity, which may be renewed daily, should be followed by a general massage of the whole limb, while passive movements of the articulations should be ordered as soon as they are possible.

During the day-time, the child should be encouraged to use its paralysed limbs, to walk, if its lower limbs are affected, to move his shoulders or his arms, in the case of the upper extremities.

The electric treatment should be continued for months and years, with intervals of rest.

A year or a year-and-a-half after the *début* of the paralysis, especially in the case of the lower extremities, an attempt should be made to correct the vicious attitudes by orthopædic appliances.

At the end of two or three years, if irreducible deformities exist, surgical treatment should be applied (section or suture of tendons, arthrotomy, etc.), and followed for some months by massage and electricity.

#### TREATMENT OF TUBERCULOUS ADENTITIS.

General treatment, including sea air, hygiene, appropriate nourishment, is of primary importance, but medical treatment should not be neglected. Cod-liver oil in winter, if tolerated by the patient, otherwise, it may be replaced by phosphated iodotannic syrup:—

Phosphate of soda,  $\frac{1}{2}$  dr.

Tannin, 30 gr.

Iodine, 12 gr.

Syrup, 10 oz.

Two table-spoonsful a day.

At the same time arsenical preparations should be prescribed, either by the mouth (Fowler's solution) or

by hypodermic injections (cacodylate of soda, 1 gr.). An injection daily for eight days, with suspension eight days, and so on until twenty-four injections are given, after which a rest of two months before recommencing the series.

Where the patient supports the administration of arsenic by the mouth, the following pills may be ordered:—

Arsenious acid, 1/64 gr.  
Hydrochl. of quinine, 1 gr.  
Powder of nux vomica, 1/5 gr.  
Ext. of cinchona, 2 gr.

For one pill; from 2 to 4 daily at meal time during 15 days per month.

To replace the loss of minerals in the organism, one of the following wafers should be taken after each meal:—

Carbonate of magnesia, 2 gr.  
Carbonate of lime, 5 gr.  
Phosphate of lime, 5 gr.  
Fluoride of calcium, 1/5 gr.  
Sugar, 15 gr.

### GERMANY.

Berlin, Oct. 3rd, 1909.

#### THE RELATION BETWEEN DISEASE OF THE STOMACH AND DISEASES OF WOMEN.

A PAPER on this subject appears in the *Ber. Klin. Wochensh.*, 24/09, by Dr. L. Lewisohn, of the Universitätspoliklinik, f. innere Krankheiten, Berlin. The writer thoroughly examined the gastric function, both as regards secretion and motility in a number of women suffering from diseases peculiar to females. His observations extended over 100 cases. 66 cases had to be excluded, as their gastric disturbances were quite independent of the affection of the genital organs from which they were suffering. It was only in a comparatively small proportion of the cases that in patients who were suffering simultaneously from both classes of disease, the one form of disease stood in a causal relationship to the other. The writer makes observations on 36 such cases. Some of his conclusions were:—

1. That examination of the contents of the stomach during the menstrual period, gravidity, and the puerperium did not give any clear conclusion as to the secretory function.

2. It was only in a comparatively small number of women who were suffering simultaneously from both gastric disorder and affections of the genital organs that the pathological process in the latter had any relation as to cause with the former.

3. Examinations of the contents of the stomach of women living in various districts, who were suffering at the same time from genital disorders, did not give a uniform result. Sommer, of Gratz, found hyperacidity, Kehrer, of Heidelberg, found a normal secretion, Winkle, of Berlin, and the writer found sub-acidity.

4. Affections of the stomach might be associated with the most varied disorders of the genital system.

5. When there was a causal relationship between the two any special nervous disorder was preceded by an alteration of the general nervous system. Disorders of the genital system might be looked upon as the starters of or deciding cause of the general nerve disease.

6. Before anything else general treatment must be taken up, if called for after careful examination of the secretory condition of the stomach. Finally, he gives a note of warning against a gynaecological polypragmasia.

#### NUCLEIN IN PROGRESSIVE PARALYSIS.

The action of this highly praised substance in progressive paralysis is discussed in a recent number of the *Prager Med. Wochensh.*, by Dr. Oskar Fischer. He first of all alludes to the fact that cases that had been diagnosed as progressive paralysis repeatedly ended in recovery. Even if the diagnosis was not quite free from objection in some of the cases, similar ones were recorded in recent literature (reckoning from about 1870), in which complete recovery took place.

In all these cases that recovered the fortunate result always followed some febrile affection, and especially long-continued fever after grave suppurations. In arriving at a determination as to the way in which the febrile affection acted, two factors especially came into consideration. First, the toxins circulating in the blood or the heightened temperature as such, might act on the body, and especially on the brain, in such a way as to assist the organism to a successful struggle against an otherwise incurable disease. One might well imagine, however, that the long-continued hyperleucocytosis of the blood was a powerful curative factor in chronic disease of the brain.

In the year 1907 the writer made repeated injections of nuclein in some cases of progressive paralysis, with a view of setting up a leucocytosis, and the course of the disease in these cases was so interesting that the investigations were continued in 1908. Hyperleucocytosis was set up by regular injections of sodium nucleinate (Böhringer), at first in large doses, later in doses of 1/2 gm. in a 10 per cent. solution 3 to 5 times a day. The injections were given subcutaneously. Soon after the injection a heightened leucocytosis set in of 16 to 25,000, and lasted three days. The first injections generally caused considerable swelling of the limb into which the injection was made, but this did not appear after the later injections. As many as 32 injections were made in one case, without any appearance of mischief.

The treatment was tried in 22 cases in which there could not be any doubt in regard to diagnosis. The cases were selected in such a way that the injections were made in every other case whilst the intervening cases were observed as controls.

Of the 22 cases treated general remissions took place in four, two of them—they were of the expansive form of the disease—became perfectly quiet, and went home sound in mind; the one two years at home is in a mildly maniacal condition, the other has been at home nine months, and has been able to resume his business, only—as his wife reports—he cannot reckon as well as he used to do. The other two cases from the first progressed as cases of simple dementia; the first came under observation in an advanced state of imbecility, and changed so far in the course of three months that he was sent home well; he returned, however, in four months bad again; the fourth improved in the clinic, both mentally and bodily, but still remains in the institution in a condition of simple paralytic dementia. Of the cases treated four are already dead, the remainder continuing without any essential change in their condition.

In the 22 control cases, on the other hand, there were no remissions whatever, and four were already dead.

The number of cases treated is too small for definite conclusions to be drawn from them, but, as the writer says, the results obtained could scarcely be accidental, and they were so interesting that they were an invitation to a trial on a larger scale, and especially so as the treatment was so simple and perfectly free from any objectionable features.

### AUSTRIA.

Vienna, Oct. 3rd, 1909.

#### DISEASE OF THE ALIMENTARY CANAL.

KIENBÖCK, in his clinical lecture at the Poliklinik, gave a long history of the various methods of diagnosis and treatment of the oesophagus and stomach. The oesophagus was peculiarly afflicted with stenosis and dilations running on to diverticular sacs, which were often difficult to diagnose without the assistance of radiography. Kienböck divides these lesions into "high pulsion diverticals," "low pulsion diverticals," and "idiopathic dilatation." Stenosis and dilatation are frequently associated, the one often depending on the other. There may be difficulty in swallowing food, but deglutition, sounding, emesis, or the oesophagoscope will not confirm the nature of the lesion. Percussion and auscultation of the thorax should never be overlooked, as this will give the location of a divertical

or dilatation from its spindle shape or irregular position. Some clinicians advocate filling the spaces or diverticula with a coloured fluid, but this is never satisfactory. The most reliable diagnosis is the radiograph, which can be clearly defined with a solution of bismuth, or it may be done with a bolus and its movement observed till it reaches the stomach, while peristaltic action, movement of heart and lungs can be noted. The radioscope may and has been of advantage in some cases, but the radiograph gives the most general satisfaction.

The high-seated pulsion divertical is sometimes called Zenker's sac, from the author, who first described the lesion in 1877 by recording 34 cases, while Starck, in 1900, published 93 of the same class. Many more have been added to our literature since that time, yet the affection is not a common one, and rarely to be met with in common practice.

Zenker believed in a congenital weakness of the pharynx as the proximate cause, and therefore a congenital condition easily accomplished by slight pressure outwards by the food, hence the origin of pulsion. Paltauf since that time records a high divertical due to poliomyelitis that would favour the origin being a spinal cause. According to Zenker's observation, the divertical commenced immediately below the pharynx, either in the median line laterally or posteriorly, but in his own cases more commonly on the left side of the œsophagus, where it followed the sheath of a muscle commencing in a space the size of a pea till it reached a size as large as a child's head, bifurcating sometimes, and holding a litre of water.

The symptoms are usually those of stenosis, irritation, pain, retching or vomiting during or after food, if pressure be applied later to the divertical vomiting or regurgitation with great quantities of mucus, but no free hydrochloric acid. There is, not infrequently, difficulty in breathing, hoarseness and laryngitis, with recurrent paralysis from pressure on the trachea, etc. The lesion is more common in advanced years, and the incidence is greater in the male than the female, and may be borne from ten to forty years till perforation, ulceration, or mediastinitis closes the scene in pneumonia or pulmonary gangrene.

Here he gave an example:—A merchant, æt. 45, had suffered for five years with difficulty in swallowing and regurgitation. The sound sometimes passed into the stomach, sometimes not. By pressing on the left side of the neck food could be brought back. With the radiograph the shadow of the heart and vessels was normal, the lungs clear, except a small margin in the left resembling a gland; diaphragm normal, but the medium shadows wider in the upper part about the second rib uniting the sternum. The patient was then given a solution of sodium carbonate and tartaric acid to drink, which greatly expanded the shadows laterally. Bismuth powder was next given, which passed to the bottom of the sac. An angular radiogram gave a recess, with the bismuth lying in front of the spine, which rose and fell with every effort at deglutition. A tube was then directed from the mouth backwards into the sac, which was found to be of a considerable size lying between the spine and mediastinum, causing a good deal of bulging of the trachea.

Eiselberg operated and removed the sac, carefully closing the œsophagus, and now the patient is perfectly healthy and strong.

The pathogenesis of this lesion is not very clear. Vetter and Rosenheim think it is due to an atony of the œsophagus in the first place, and probably induced by catarrh or other anatomical changes of the mucous membrane that may finally produce cramp and destruction. Mikulicz was a firm believer in a cardio spasm of the œsophagus as the principal cause of the lesion. Meltzer attempted to prove this by physiological experiments by irritating the cardia which acted on the terminal of the vagus and produced the morbid conditions usually present. Paltauf, on the other hand, supports a theory that the disease is an idiopathic dilatation, and that atrophy takes place in a circular band of the œsophagus, as he had found this in some of his own cases, where the vagus nerve was found embedded in a band of atrophic tissue.

THE INTERNATIONAL MEDICAL CONGRESS, BUDAPEST.—In another part of our present issue will be found abstracts of some of the important papers read at the Congress. Among the excursions, a popular one was that of a visit to the "Apenta" springs, where the process of raising the bitter waters was shown, together with the ingenious machinery employed. Everything, in fact, connected with the raising, bottling, and dispatching of this popular aperient water is done severally by English, American, or German machines, and the scrupulous cleanliness that prevails throughout, so that the water does not come into contact with the hands of the workers, was fully explained and exemplified to the visitors. Nevertheless, medical surveillance is exercised over the employees, so that there shall be only healthy persons on the premises. During three or four days parties consisting of several hundred members of the Congress went to see these wells.

## FROM OUR SPECIAL CORRESPONDENTS AT HOME.

### EDINBURGH.

INTRODUCTION OF PROFESSOR ARTHUR ROBINSON.—Professor Robinson, who has succeeded the late Professor Cunningham in the Chair of Anatomy at Edinburgh, delivered his opening lecture in the Mac-ewan Hall, on October 1st. Principal Sir William Turner, in introducing the new Professor, said that it was not an easy thing to follow a man like Cunningham, and cordially welcomed Professor Robinson to his new chair. Professor Robinson's subject was "A Glance at Anatomy from 1705 to 1909," and in his lecture he drew the attention of his hearers to some of the broader features of the history of anatomy and the history of the chair of anatomy in Edinburgh. Having sketched the history of the chair down to the occupancy of Sir William Turner, Professor Robinson said that the influence of that gentleman as a teacher of anatomy might be gauged to some extent by the fact that his pupils held, or had held, the chairs of anatomy in Edinburgh, Glasgow, St. Andrews, Newcastle, Manchester, Liverpool, Cardiff, Oxford, King's College (London), Dublin, Belfast, Melbourne, Sydney, Montreal and Toronto. He knew of no other such record. In the past hundred years the science of anatomy had made more progress than in any previous time. The results got from improved methods and improved instruments, in the hands of an army of investigators, would amaze the anatomists of the latter part of the eighteenth century could they return among us. A knowledge of the true form of the heart had only been gained comparatively recently, and a proper conception of the shape and size of the stomach was a still more recent acquisition which had been provided by the observations of Cunningham and Waterston. Our knowledge of the anatomy of the nervous system had been revolutionised during late years by skilful experiments and observations. Nature, as revealed by anatomy, showed plainly that she had no beliefs in any general equality. She produced her children in myriads, cast them into the sea of circumstance, approved and helped only those who could swim, and rewarded them according to their performances. The riddle of life was not yet solved, but numbers had sought and would seek, and in the search some would find, in the future as in the past, knowledge useful to mankind.

MEDICAL INSPECTION OF SCHOOL CHILDREN.—The Aberdeen County Committee on Secondary Education laid before a representative meeting of the School Boards interested a proposal that for the purposes of medical examination the whole county, including burghs, should be treated as one area. It is proposed to appoint a principal Medical Officer at £300 per annum, and an assistant at £200, with increment and travelling expenses, and to utilise the services of the district nurses in the work. The estimated cost during the first year, including salaries, administration, and apparatus, is £2,050, which will be divided among the various boards in the event of the scheme being adopted. In Dumbarton the first report on the medical

examination of children is now published. It deals with 634 scholars, and one of the salient features is that the children are considerably under the average weight, though equal in height to the figures of the Anthropometric Commission of the British Association. Dr. Little suggests that an experiment should be made in the way of feeding a selected group of children.

### GLASGOW.

THE procedure in the appointment of a CHIEF MEDICAL OFFICER FOR THE INSPECTION OF SCHOOL CHILDREN,

under the care of the School Board, of the very important parish of Govan, gave rise to protests on the part of several members of the Board. As mentioned last week, a Glasgow man was appointed, who was, in fact, the assistant to the occupant of the chair of Forensic Medicine in the University. It appears that his appointment was carried only by the casting vote of the chairman. Now the appointment was made by the Board sitting as such, and is quite legal. But, further, the procedure followed was reasonable and not "absolutely dishonourable and contemptible," as has been stated. What happened was this: Out of 74 applicants for the post, the Board in committee of the whole Board made a short list of nine. Subsequently the committee reduced the list to five, whom we will call Drs. A., B., C., D., and E., and, by subsequent voting, Dr. E. (Dr. Brown) was dropped from the list, and by a final vote Dr. D. The committee agreed to recommend that the appointment should be made from among Drs. A., B., and C. When the Board met to receive the recommendation and make the appointment, Dr. C. had been appointed for Glasgow, and was therefore no longer a candidate. A motion was made to reinstate Dr. E.'s name among those to be voted on. This was done, and he was appointed. The complaint is that Dr. D. had a preferable right to have his name voted on, Dr. E. having been dropped before him. But for the reason already stated he obviously had no such right.

### THE MEDICAL PRELIMINARY EXAMINATION.

The pass lists of the Medical Preliminary Examination at Glasgow University show that while 25 passed in Latin, only 1 passed in Greek. This is scarcely fair to Greek, to which medical nomenclature owes so much. Greek is optional in the examination, and French or German can be taken instead. A considerable number passed in French, but none in German.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—The opening meeting of the session took place on Friday last, October 1st, when the President, Robert Muir, M.A., M.D., Professor of Pathology in Glasgow University, delivered his Presidential Address on "The Doctrine of Inflammation," in which he remarked that the want of a generally accepted definition of inflammation led to confusion and needless discussion in the consideration of clinical phenomena. After a brief historical survey of the nature of pathological processes and the compound character of inflammation, he arrived at the general conclusion that it is impossible to define inflammation as a pathological process and at the same time to maintain its relation to the recognised cardinal signs. It should only be used as a convenient, though somewhat indefinite, clinical term.

### BELFAST.

THE QUEEN'S UNIVERSITY OF BELFAST.—The Senate of the new University met at the College on the 28th ult. and proceeded to nominate a secretary. Mr. J. M. Finnegan, B.Sc., B.A., was nominated, and subsequently appointed by the Commission. Mr. Finnegan has had many years experience in teaching work, preparing students for examinations with great success, and his popularity with the students will no doubt smooth his way in the performance of his new duties.

A GOLD MACE FOR BELFAST UNIVERSITY.—The Vice-Chancellor submitted a letter from Mr. William Gibson, of Donegall Place, Belfast and Regent Street, London, offering to present to the University a gold mace of the finest quality of gold, and of the same

size as the Royal sceptre. Needless to say, the offer was accepted with much gratitude.

THE POLLUTION OF BELFAST LOUGH.—The question of the pollution of the shores of the Lough by the city sewage always assumes a more acute form at this time of year, when the smell from the decaying matter becomes more than usually offensive. Consequently, the Belfast Foreshore Committee, a body composed of residents in the districts specially affected by the nuisance, has hit on an appropriate time for the publication of a special report, giving the history of the Corporation's dealings with the problem, and their proposals for future schemes. It is impossible even to summarise the matter here, the question is so complicated; but it may be said that while the Corporation has been most dilatory in fulfilling the duties imposed upon it by Act of Parliament, it can shelter itself to some extent behind the various experts who have examined and reported, their reports and recommendations being mutually destructive. In Belfast Lough we have to deal with a large area of slob land exposed at low water, on to which the sewage from some 380,000 inhabitants is discharged. On this the soft green seaweed known as *ulva latissima* flourishes in enormous quantities, and as it withers and decays it fills the air with sulphuretted hydrogen derived from the sulphur in its composition. The latest proposal of the Corporation is one for the sedimentation treatment of the sewage, but the Local Government Board do not consider this efficient, and even if it be accepted as a preliminary treatment to some more thorough method, the tanks will have to be larger than those proposed by the Corporation. The latter were designed to store the sewage for 8½ hours, but the Board say that 12 to 14 hours will be necessary. It is now proposed to ask the Royal Commission on Sewage Purification to nominate six persons competent to determine what further purification, if any, is necessary to comply with the Act of 1899.

## LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

### BONE-SETTERS AND INFANTILE PARALYSIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—As your journal is at the present moment engaged in a campaign against quacks and quackery, I venture to bring before your readers some of my personal experiences of the ways of the bone-setter. During the current year I have had under my care seven cases of chronic infantile palsy: of these no less than five had previously consulted one of the above-mentioned class of impostors. In every instance a diagnosis was vouchsafed of "joints out" or "leaders off," and a cure promised in a few weeks. I will quote briefly two examples:—

(1) Girl (14), paralysis of left lower limb, together with weakness of back muscles at same side, causing some degree of scoliosis. The lesion had occurred at the age of four. The parents—well-to-do people—had consulted the family physician, and the child was subsequently taken to a specialist. After about a year's treatment by massage—without, however, any attempt having been made at electrical stimulation—her parents were informed that nothing more could be done. Not satisfied with this verdict, they presently took the patient to a bone-setter. This gentleman announced that "the leaders of the spine were off," and that he would soon make everything right. He proceeded to carry out daily manipulation for a period of six weeks, charging a fee of five shillings per sitting. The net result of these proceedings was to throw the child into general ill-health, and the "leaders" remained "off," as before.

(2) Girl (4½), suffered from weakness of right leg from age of six months: attributed by parents to a fall. The medical attendant diagnosed infantile paralysis, and after six months' treatment (here, again, without electricity) gave an unfavourable prognosis. As the child grew, walking became possible to some

extent, but the knee-joint on the affected side was seen to stick out backwards to an abnormal extent. The parents—people, it may be noted, in fairly good circumstances—now consulted a bone-setter, who stated that the child was suffering from a dislocated knee, the result of an injury. Then followed a period of two months' distress for parents and child, at the end of which time they lost faith in the man's promises of cure, and abandoned his so-called treatment. This was a year ago. At the present date, although the hip and thigh muscles are but slightly paralysed, the knee-joint is "wobbly" to a degree, and there is complete paralysis of the calf-muscles and peronei. Possibly this may all be due to the original attack; but it is at least reasonable to assume that brutal handling for a period of eight or nine weeks did something to increase the existing lesion.

For an ignorant man to pose as a setter of fractures and reducer of dislocations is bad enough in all conscience; but that such a person should be allowed to torture helpless children, and delude parents into anticipating a speedy cure of what is, after all, to a greater or less extent, an incurable disease, is purely a monstrous state of affairs. Such an expression of opinion in a medical paper is, however, a mere preaching to the converted. It is more to the point to ask can we, as individual members of the medical profession, do anything to lessen this evil? In both the above cases the orthodox practitioner had had, so to speak, first innings. I am convinced that it is a great mistake ever to tell the parents of such children that nothing more can be done. If it were even approximately true, it would be injudicious—for treatment of some sort they will have. But it is never true until the patient has reached full growth, and often not then. No case should be pronounced incapable of further improvement until a course of Faradism has been tried, and all muscles not hopelessly paralytic should be stimulated from time to time until the period of development is over. The effect of interrupted currents on the trophic function of the spinal cells should never be forgotten, for, apart from their effect on individual muscles, their frequent application will, to a great extent, obviate the increase of "relative shortening" so common in this disease. Such treatment, together with the prevention of deformities, the provision, and supervision if need be, of suitable apparatus, will furnish ample justification for keeping in touch with these cases; and, incidentally, by showing the parents that the doctor is not merely folding his hands and muttering *Kismet*, render it unlikely that they will wander from the true fold to seek the aid of rogues and charlatans.

I am, Sir, yours truly,

FRANCIS HERNAMAN-JOHNSON,  
M.B., Ch.B., R.N. (Ret.)

Bishop Auckland,  
September 30th, 1909.

#### SOLDIERS' TEETH.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—With reference to your editorial on the dismissal from the Service of a batch of trained soldiers otherwise physically fit, merely because of defective teeth, one would like to know whether the cases were seen and reported on by a dental surgeon besides the medical officers. In the days of the "Brown Bess" musket it was necessary that the men should have sound front teeth to enable them to bite the cartridges, but nowadays, a soldier's teeth are required for no other purpose than mastication. Nature provides sixteen teeth in each jaw; but, if sound, half of this number are quite enough for chewing purposes. It is absurd to attempt to provide soldiers with artificial teeth; they are mostly of very little use in mastication, and in the majority of cases need frequent repairs and attention. It is probable that the teeth of the men dismissed could have been made efficient by filling or capping—covering in decayed crowns with complete metal caps. Caps can be made of gold of a low standard; that of 9 carat, silver being mainly used as the alloy, is comparatively inexpensive, and

very hard and durable. Teeth of which the nerve has not been exposed treated in this way will last a lifetime; and a few molars so strengthened would suffice to do the chewing work of the soldier for much longer than the usual term of service.

I am, Sir, yours truly,

HOSPITAL DENTIST.

London, W., October 4th.

#### THE DECLINING BIRTH-RATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—If your readers wish to study a most able statement of the case against reckless use of artificial checks on the number of children as a remedy for social evils, I would refer them to the classical work of Arnold Toynbee, "The Industrial Revolution," 7th ed., 1906, p. 112, *et seq.* If you will allow me I will briefly summarise the statement. The problem is a vital one, and must be faced in spite of the suggestion that it should only be discussed "under the decent veil of a dead language." He examines the question in the light of French social history. He shows that in Departments of France where the population is on the decline owing to the widespread adoption of artificial checks, although the districts are the best cultivated in France, and enjoy great material prosperity, the general happiness promised is not found. These Departments show most crime, one-third being indecent outrages; and infanticide is rife. There is the evidence of experience against the idea that a stationary and materially prosperous population will be necessarily free from vice. A stationary population is not a healthy condition of things in regard to national life; it means the removal of a great stimulus to progress. The incentive to invention and enterprise is removed; it is certainly true that the struggle for existence is essential to progress. Such practices, moreover, prove injurious to the children themselves. French parents strive to leave to each child a comfortable maintenance; it would be better for them to be brought up decently, and then left to the battle of life. Much genius and inventive power has come from men belonging to large families, obliged to win their own way. The question cannot properly be considered from the point of view of wealth alone; the family life is the source of all that is best in national life. The necessity of supporting and educating a large family is a training and refining influence in the lives of the parents—the one thing that can turn them into good citizens. French practices are unnecessary in England. Prudence in marriage in every class is alone called for. The willing emigration (there is limitless space and scope in our vast colonies) of some of the children meets all difficulty. The question whether there is room in the world for more need not be considered, for there is room, and in the interests of civilisation it is desirable that a nation with a great history and great qualities should advance in numbers. The improvement of the quality of the lower strata of the people can be brought about by social reforms, improvement of their dwellings, better education, better amusements. The true solution is to be found in a high ideal of spiritual life, a growth towards a purer and higher condition of society.

I am, Sir, yours truly,

ANOTHER STUDENT OF SOCIOLOGY.

October 2nd, 1909.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—For the life of me I fail to see how the national wealth of any country touches the question of a declining birth-rate, seeing that such a small minority participate in the wealth. No civilised community has ever yet existed, neither ever will (nature not permitting) that can supply a sufficient number of wealthy and luxurious persons who deliberately suppress their families for social enjoyments, and upon whom the stigma of a declining birth-rate can be brought home. Socialists, with whom I have no sympathy, tell us that "every year about 700,000 people die in the United Kingdom, 600,000 of these

do not leave any property worth mentioning," and I have no doubt these figures would apply approximately to other countries. It seems clear, therefore, we must look to the vast majority to account for the decline. Here ease and luxury are out of the question. What evidence have your correspondents in support of their extraordinary ideas?

I take it as one of the defects of civilisation that there has existed from time immemorial the outgrowth of town at the expense and diminution of agricultural populations. This readily explains unemployment and the increased tensivity of competition, hence the declining birth-rate. Without this explanation it would be impossible to account for excessive competition in countries like Australia, Canada and New Zealand, which at present are neither cultivated nor populated.

I am, Sir, yours truly,

CLEMENT H. SERS, M.R.C.S.

Brighton, September 30th, 1909.

## OBITUARY.

SIR THOMAS SMITH, Bt., K.C.V.O., F.R.C.S.

WITH much regret we announce the death of Sir Thomas Smith, Bt., K.C.V.O., at the age of 76 years. Sir Thomas was educated at Tonbridge School and at St. Bartholomew's Hospital. He was closely connected with the hospital during the whole of his professional life, and was a Consulting Surgeon and Lecturer at the institution, whilst his capabilities as a teacher and adviser to the students were such as to make him revered and admired by the whole of the medical staff. Besides his appointment as Honorary Serjeant Surgeon to the King, Sir Thomas was also a Consulting Surgeon to the King Edward VII. Hospital. Formerly he had been a member of the Council and a Vice-President of the Royal College of Surgeons. Many members of the Royal Family were numbered among his patients, and he also attended the late Mr. Gladstone. He was of a most genial and kindly disposition, and his loss will be lamented by many friends and former pupils. His death has removed a well-known and distinguished personality from the professional world.

## SPECIAL REPORTS.

### THE OPENING OF THE MEDICAL SCHOOLS.

#### MIDDLESEX HOSPITAL.

THE London Medical Schools commenced their new year on Friday last, and in some of them the opening took the shape of a formal address.

At Middlesex Hospital Mr. Shackleton, who was accompanied by Mrs. Shackleton, spoke on medical work within the Antarctic circle. He said explorers did not go in much for theory. They found things had happened, and they left people whose job it was to find out what these things meant. In medical science there had been some very interesting things in the Antarctic regions. On his expedition they had three doctors and surgeons. The expedition came through without any deaths, due to the fact that they had these men with them. One man lost an eye down there, and one of the principal London doctors who looked after that sort of thing saw the place where the eye had been, and said that the operation was done as well as it could have been done in a London hospital. That was very satisfactory, considering that the operation was performed when the man was lying on a board in a very low temperature. The only other serious operation was due to frost-bite. One man lost his big toe. He still carried his toe about with him in a bottle as a trophy.

There was some very strange things in the Antarctic. For instance, it had been discovered that the rotifers brought back on the *Nimrod* which could live in a temperature 50 to 60 degrees below zero, could be heated

up to 230 degrees Fahrenheit, and then frozen again and come out smiling. He believed that was all the more strange because these little animals had to take the actual temperature of the surrounding atmosphere. That was not the case with human beings, but their temperature in the Antarctic suffered some great reverses, if he could put it that way. On the plateau the temperature went down many degrees below zero, and he believed that usually a white sheet was put on a man when he got down to that. But after meal times their temperature went up to normal. People often said that it was remarkable that they never caught colds in the Antarctic or Polar regions. The members of his expedition never caught a cold until they opened a bale of clothing that had been bottled up in England. Then they all caught colds. Those who went out directly into the cold winter's night lost their cold at once, but those who remained in the hut kept theirs for two or three days. Those were small points, but they were of interest as practically touching things which perhaps could not always be discovered in the laboratory.

Mr. Shackleton distributed the prizes to the students, and Mrs. Shackleton presented gold, silver, and bronze medals to the most distinguished nurses of the year. Prince Francis of Teck, Lord Cheylesmore, the members of the board of governors, and the honorary staff of the hospital, received the visitors, and the famous explorer and Mrs. Shackleton inspected the hospital's cadet company of the University of London Officers' Training Corps.

In a marquee erected in the grounds there was a large assembly of the friends of the students, and here Dr. J. Strickland Goodall delivered an Introductory Address on "Walking the Hospital."

#### ST. MARY'S HOSPITAL.

At St. Mary's, the Principal of London University, Dr. Miers, delivered an Inaugural Address.

"It has been," he said, "too much the fashion to decry youthful efforts, and to endeavour to persuade ourselves that knowledge and experience are required before anything good comes out of a man unless he be a Heaven-born genius.

"For my part, I believe this to be really the productive period of an ordinary man's life, and that he who takes the trouble to search the history of his own mental development will find that anything which is the unaided product of his own intellect dates from this period; that the germ of any original thought which finds its expression in his more mature life is to be traced to late boyhood or early manhood."

Dr. Miers continued by entering a protest against the present tendency to insist more and more upon the necessity of preparation. "Before you can begin one subject you are told that you must master another, and a great part of our life is occupied in preparation for something else; indeed, there are people who, not only in their student days, but through their whole life, are so much overwhelmed by the necessity of preparation that they spend it in preparing for things that are never done, endeavouring to master the ideas of others before daring to have ideas of their own, and pass an existence of promise without ever attaining to performance. It is quite clear that if you never undertake anything until you are fully and completely prepared, you will not get very far."

He paid a tribute to enthusiasm, and welcomed the more liberal view of education. He went on to emphasise the value of enthusiasm and to protest against the view of the old school that it is sound policy to teach the distasteful because of the greater effort needed for the assimilation of such matter. He welcomed the more liberal, saner view that has come into modern education, as shown by the contrast between the time-honoured "crib" and such translations as those of Gilbert Murray.

"I would assert," he continued, "that we, in our active life, need the inspiration of a theory, the illumination of an idea, which can glorify the drudgery of preliminary studies and the details of ordinary practice.

"That is the spirit of modern scientific work; the

restless desire to prove or to demolish the theory on which we are working for the moment, and to discover the principles which underlie all that we can observe or do. It is this faith in a principle, this hope that we shall discover it, this certainty that our theory is leading us on the way to its discovery, that gives to even the drudgery of scientific routine work such a fascination for those who have once tasted the delight of scientific research.

"Work illuminated by a theory, or carried on with a general principle in view, cannot fail to be interesting, even though it be only work required for preliminary examinations.

"The moral that I wish to draw for my present purpose is this: In all your work have a theory and believe in it, let it be your own, if possible, now in the creative and inventive period of your life; test it, not by the opinions of others or by their knowledge, but by your own observation and your own experience. No matter if you have later to reject it. Work uninspired by an idea is as aimless as a life uninspired by principles. The idea, especially if it is one's own idea, lends an interest and an excitement to scientific work, and, indeed, to all work, and, like the wishing cap of Fortunatus, transports its owner to a new world."

Dr. Miers illustrated his contentions by reference to the work of Pasteur and Darwin, and continued:—

"I wish that teachers would remember that to the medical student subjects should be taught as the physics, chemistry, etc., of medicine, illustrated by examples drawn from the art of medicine, illustrating the general principles and current theories of the science of medicine. It would, no doubt, be very satisfactory if every medical man would have been first a mathematician, then a physicist, then a chemist, and so on through the different stages until he finally became a doctor. But life is not long enough for this process, and the minds of ordinary men are not able to contain so much knowledge.

"As regards the learning of these subjects, if the medical student will regard them with the eye of a doctor, and never lose sight of their medical significance, they can, I think, never fail to have an interest for him. And if he wishes to do this he must keep a firm hold upon the general principles and the wide theories of his own science which embrace those of all other sciences, because they are, in fact, all manifestations of the same general principles.

"If you read the history of the great discoverers, or of those who have made any successful advance in science, you will find that this is the spirit by which they were animated in their student days; the determination to understand what they learned by getting a grasp of general principles, to put an idea of their own into it, and so to get something new out of it."

He concluded:—

"Herein is the great charm of scientific work; in every observation or experiment, time-worn exercise though it may be, there is something new to be seen, some discovery to be made by those who have eyes to see it and an idea to guide them. To such a person they can never be mere exercises, they are a field of unknown possibilities. I suppose there is no science in which these possibilities are more rife than in yours; so, in spite of my ignorance of the principles of medicine, I have no hesitation in asserting again that the student who can work, however humbly, in the spirit which animated Darwin in his young days, is certain to find an intellectual interest that cannot otherwise be acquired, and is certain to be rewarded by some advance or discovery, some new fact, or some new thought, that will be a full compensation for any labour that he may have incurred in the process."

#### UNIVERSITY COLLEGE HOSPITAL.

University College Hospital has been for some time under its own management. Sir John Tweedy delivered the Opening Address there, at 3 p.m., in the library of the school. Contending that character, with all that the term connoted—thoughtfulness, sympathy, courtesy, and culture—was essential to ensure success in practical affairs, he said that knowledge was one of the elements and conditions of power, but to be

effective it had to be protected by wisdom. Conspicuous inaptitude for practical art was nowadays scarcely possible owing to the present examination system. But this, as he showed, had not always been so, for Arnold of Villanova had recorded in the thirteenth century that he knew an excellent professor of natural science, learned in medical theory, who could not treat the simplest ailment.

Sir John estimated the quack as a man who was able to appreciate arguments and similarities, but who failed to appreciate differences. He proceeded to show how a change had come over medical education. "Heretofore the education of the student has been chiefly literary, based upon pedagogic authority and the dictatorship of books. Henceforth both the character and method of study will be altered. The knowledge taught must be knowledge capable of verification."

Discussing the difference between observation and experiment on the lines laid down by Mill, Sir John Tweedy illustrated his remarks by references to medical discovery. "The science of medicine," he said, "has been advanced mainly by the researches of those who have not been directly engaged in the treatment of disease. When new knowledge has been discovered by these means, it has been received by competent judges, and, by the influence of their authority, it has been accredited and diffused.

"Failure to appreciate the difference between the dissemination of knowledge and the advance of knowledge has given rise to much confusion of thought and not a little waste of endeavour. Perhaps the crudest manifestation of this confusion is the belief, real or feigned, by some persons, that inquisitorial experiments are performed in hospitals on men or on animals, or both. Less crude—nay, even creditable in a sense—is the notion that, by establishing sanatoria or endowing special hospitals for the treatment of particular classes of general diseases, it is possible to solve the problem of the nature and origin of these diseases and to hasten the discovery of the means of prevention and cure. Logically, this assumption is false; economically, it is wasteful. It is based on a misapprehension of the function of hospitals and of the methods by which scientific discoveries are made. Far be it from me to discourage the most generous pecuniary support of hospitals. Money is greatly needed for their maintenance, and will be needed in increasing proportions if hospitals are to avail themselves of the resources which scientific research is continually placing at their disposal. The great desideratum of our day is adequate endowment of biological and pathological research as the surest and most humane way of discovering the nature and cause of disease and the means of its prevention. Clinical observation only deals with disease when and as it manifests itself in man and animals; it throws but little light upon the causes of disease or upon the intimate processes which constitute the pathological state.

"Supremely useful as hospitals are for the purpose of treating the sick by the help of the best skill and knowledge of the time, and as schools for the training of successive generations of medical practitioners for the service of the community, it is nevertheless true that most of the capital discoveries of scientific medicine have been made outside hospitals and very often apart from clinical observation altogether. Among the most remarkable of these discoveries I may mention those relating to malaria, Malta fever, yellow fever, and, I might add, other diseases, which have baffled the best clinicians for centuries. In surgery, too, it may be said that the scientific basis of the modern aseptic method has been established not by clinical observation, but by experimental research. Another simple but striking instance supporting my thesis is afforded by the history of the use of the ligature for the arrest of hæmorrhage from wounded arteries. Nothing, it might seem, can be more obvious than to tie a bleeding artery. The records of surgery inform us that the ligature has been so employed, more or less systematically, by surgeons for over 2,000 years; but, simple as the procedure may seem, the true method of tying an artery was not established until the beginning of the last century."

Sir John went on to say:—

"Dr. J. F. D. Jones, at the beginning of last century, by a series of ingenious experiments, mostly on horses, proved that the endeavour of surgeons to apply the ligature without injuring the arterial tunics was precisely the cause of the failure of the ligature permanently to arrest bleeding. Jones demonstrated that the true method was to employ a small, firm ligature drawn sufficiently tight to cut through the inner and middle coats without rupturing the tougher and external coat. Every practical surgeon will bear testimony that, as the result of Jones's experiments, tens of thousands of lives have been saved.

"I have lingered about this question because you, as future practitioners of medicine, will have to form an opinion on the justifiability of experiments upon living animals for the purposes of scientific research, and if you are satisfied that these experiments are justifiable, with proper safeguards, you will be called upon to defend the practice and to justify your opinion. To do this intelligently it is necessary not only that you should be acquainted with the arguments for the defence, but that you should also make yourself master of the arguments on the other side. It is not enough to ascribe the opposition of the public to ignorance or fanaticism. There may be either or both, but objection can only be overcome and acquiescence gained by enlightening and educating the public mind. It should be remembered that the mass of a nation must be convinced of the value of a general principle which is being carried out, else what we might judge the most salutary change will be ineffectual. Ritchie, in discussing the Rights of Minorities, has remarked that on matters of public health only the scientific expert can, in the first instance, form a sound judgment. In democratic societies there is often a distrust of scientific opinion. The remedy is not despotism, but public enlightenment, and the scientific specialist is bound, therefore, by patriotism, as well as in the interests of his own science, to lend what aid he can to the popularisation of science, from which he is too apt to recoil. It is the sole antidote to ignorance or pseudo-science. Those whom science neglects, fanaticism and quackery will claim for their own."

At King's the Act for incorporation with the University received the Royal Assent in August of last year, but, unfortunately, for formal reasons, the Act is not to take effect until next January.

At St. George's, Dr. H. D. Rolleston, Senior Physician to St. George's Hospital, in his Introductory Address at the opening of the session of the Medical School attached to the hospital, reviewed the influence of St. George's men on the advance of medical knowledge.

Other hospitals have prepared for the winter. St. Thomas's has now plenty of accommodation since the building additions have been completed, including arrangements for a maternity ward. The Old Students' Dinner took place on the evening of the 1st inst. at the Hotel Cecil, Mr. Lawford in the chair.

Guy's has also completed building arrangements.

Charing Cross and Westminster are proceeding "as before."

The London School of Tropical Medicine is continuing its prosperous career. The school oration will be delivered on the 26th inst. by Professor Osler.

#### HEALTH RESORTS—VERNET LES BAINS.

VERNET LES BAINS is situated in the Eastern Pyrenees (Pyrenées Orientales), and undoubtedly deserves the name of "Paradise of the Pyrenees." Independently of the value of its mineral waters, one can hardly imagine a spot with more peaceful surroundings, more perfect atmospheric conditions, and more admirable hotel accommodation.

Vernet is reached from Paris by the Orleans Railway to Toulouse, then by the Midi line to Villefranche.

The journey from Paris to Toulouse takes about 11½ hours, and from Toulouse to Villefranche more than 5 hours, on account of the horseshoe curve running through Carcassonne, Narbonne and Perpignan. Two delightful breaks can be made, one at Toulouse—a very interesting town on the Garonne, with a superb museum—another at Carcassonne, the "Cité" of which to the south-west of the town is an ancient fortress of the 11th and 13th centuries, containing a town of 1,200 inhabitants and a magnificent cathedral church, part of which is 11th century and part 13th century, with a tomb of Simon de Montfort. After Perpignan the line, now single, passes very close to the Mediterranean, winding amongst lagoons, called here "étangs"; here, too, it has an upward incline for 52 kilometres to Villefranche. From various points the traveller can observe not only many frontier chateaux in ruins, but also the majestic Canigou which so effectually shelters Vernet. With reference to this mountain, it is whispered at Vernet with bated breath that when an English patient, gazing at its summit, softly murmurs, "*Can I go*," there? his cure is nearly an accomplished fact.

From Villefranche station a drive of about two miles gradually ascends through a picturesque valley, flanked by a semi-circle of frowning, cloud-tipped mountains. Here the pure air, scented by the pines, revives the tired traveller, and makes him forget the fatigues incident on his railway journey. The strange assortment of vehicles is a source of wonder, very obsolete motor char-à-bancs, three-horsed (unicorn) wagonettes with the inside turned the wrong way, and with a box-seat of a coach back and front, even an ancient diligence, coupé and all—with five horses—every vehicle, however, perfectly safe and driven with skill. The old village of Vernet, with chalets peeping out here and there is passed, a fleeting glimpse being caught of the distant mountain of St. Martin du Canigou, where the delicious Liqueur du Canigou is made; the robust visitor at once feels eager for the climb to the monastery, whilst the invalid hopes that with such atmospheric and climatic surroundings his pains and aches may disappear and he, too, may soon be in a fit condition for the ascent. At the end of the village, after passing the Hotel des Bains Mercader and crossing the Cady (called a river, but really a torrent), one is greeted with a vista of hotels, casino, villas, etc., framed in a delicious park and having for background a comparatively small mountain covered with trees, the Alsina (the property of the establishment), on which may be noticed a few paths winding amongst pine and olive trees, Japanese medlars, mimosas, etc.; all these flora, common enough round Vernet les Bains, bearing silent but indisputable witness to the temperate climate enjoyed at this station, at an altitude of 2,000 feet. The English visitor on entering his hotel is at once struck, not only with the French coquetterie in all the apartments, but also by the admirable ventilation as shown by the purity of the air in all the rooms and the complete absence of that stuffiness not altogether unknown in many caravansaries; after a few days he will realise also that the hygienic arrangements leave nothing to be desired, the drainage being perfect and the No. 100's kept as in England.

It may be noted that Vernet possesses one great advantage over the other sulphur springs of the Pyrenees, namely, that being at the eastern end of the mountain range, and therefore at the extreme south of France, it is really situated in a more southern latitude than Nice, and, indeed than the whole "Côte d'Azur"; therefore, owing to the mildness of its climate, it is available all through the year, even in the depth of winter. There is no cold, no dampness, no wind, no fog. A very picturesque, and from a hygienic point of view, a very important sight is the dairy which supplies the milk to the establishment. A stroll of about ten minutes from the hotel on the left bank of the Cady brings the explorer to a model stable, the large door of which opens on to a green pasture sloping down to the torrential stream. In this shed nine milch

cows can be seen in perfect health and condition; these are twice milked in the twenty-four hours. The cleanliness of everything, from the straw in the stalls to the dress and hands of the keeper of the animals, is irreproachable. The man is evidently proud of the cows and their surroundings.

The waters of Vernet les Bains are all of the sodium sulphate class, and the thermality of the springs ranges from 45 to 165° F. There are twelve natural springs yielding an immense quantity of water. The analysis of two of them is as follows:—

#### THE VAPORARIUM SPRING:

Temperature, 127° (53° Centigrade).

Analysis (per litre-unity):—

Alkalines ... ..	0.0726 (SO <sub>2</sub> H <sub>2</sub> )
Sulphide of sodium ... ..	0.0189
Hyposulphide of sodium ... ..	0.0032
Silicate of sodium ... ..	0.0286
Free silica ... ..	0.0422
Bicarbonate of sodium ... ..	0.0621
Bicarbonate of calcium ... ..	0.0073
Bicarbonate of iron ... ..	Traces
Sulphate of sodium ... ..	0.0327
Sulphate of potassium ... ..	0.0083
Sulphate of magnesium ... ..	Traces
Chloride of sodium ... ..	0.0151
Organic matter ... ..	0.0127
Dry sediments ... ..	0.235

#### THE URSULE SPRING.

Temperature, 108° (42° Centigrade).

Analysis (per litre-unity).

Alkalines ... ..	0.0727 (SO <sub>2</sub> H <sub>2</sub> )
Sulphide of sodium ... ..	0.0156
Hyposulphide of sodium ... ..	0.0048
Silicate of sodium ... ..	0.0280
Free silica ... ..	0.0418
Bicarbonate of sodium ... ..	0.0008
Bicarbonate of calcium ... ..	0.0076
Bicarbonate of iron ... ..	Traces
Sulphate of sodium ... ..	0.0306
Sulphate of potassium ... ..	0.0053
Sulphate of magnesium ... ..	Traces
Chloride of sodium ... ..	0.0136
Organic matter ... ..	0.0124
Dry sediments ... ..	0.229

The Mercader baths communicate directly with the hotel of the same name, and are fitted up with all modern hygienic and curative desiderata. All the most perfect types of apparatus for hydrotherapeutic medication are employed. Here we find a douche room, a douche massage room, "Aix-Douche," where the marvellous effects of under-water massage can be enjoyed; an inhalation room, a pulverisation room, a room specially devoted to vaginal and rectal douches; a douche Tivoli room (wave bathing), foot baths, etc.

The Commandants Baths contain apparatus for douches, inhalations, pulverisations, etc., of the latest kind, also vapour baths; but their great charm is undoubtedly the magnificent swimming-bath, which shows a large expanse of warm, running, sulphurous water, in which a swim can be enjoyed in the winter as well as in the summer.

The maladies successfully treated at Vernet during all seasons are rheumatism, arthritis, gout, neuralgia (sciatica), neurasthenia, chronic bronchitis, bronchial catarrh, nose, throat, and ear affections, sprains, dislocations, old fractures, dyspepsia, anæmia; but, above all, convalescents and those who desire to regain their lost strength and to repair their digestive organs are absolutely certain to derive immense benefit from a visit to Vernet. In the words of Prof. Landouzy, "Vernet may be regarded as a hydrotherapeutic station with a double aspect—sulphurous and climatic."

## LITERARY NOTES.

MESSRS. J. AND A. CHURCHILL inform us that the *Medical Directory* for 1910 will contain a descriptive list of all the most important British spas and health resorts. It has been compiled by Dr. Norman Hay Forbes, ex-Vice-President of the British Balneological

and Climatological Society. We believe it will be a great help to medical men in deciding where to send their patients for balneological and climatological treatment. We may add that the *Medical Directory* for next year is now being compiled, but the editors can still receive information.

\*\*\*

IN addition to the list of new editions of standard medical works referred to in our last issue, we may mention that Messrs. Churchill have just published another revised edition of Dr. Hale White's "Manual of Materia Medica." This work was first published in 1892. Its great popularity is evidenced by the fact that an eleventh edition is now called for. Messrs. Longmans have issued a new edition of "Gray's Anatomy" (the seventeenth), revised and edited by Dr. Robert Howden, Professor of Anatomy in the University of Durham. The notes on "Applied Anatomy" have been revised by Dr. A. J. Jex-Blake and Mr. W. F. Fedden, F.R.C.S. Messrs Longmans also announce for publication in a few days a new work on "The Relation of Medicine to Philosophy," by Dr. R. D. Moon.

## LABORATORY NOTES.

### "P.G.B." LIQUEUR BRANDY.

WE have examined a sample of this brandy, and we find it to contain 46.96 per cent. of alcohol by volume (equal to 82.30 per cent. of proof spirit) and 1.02 per cent. of extractives. The fixed acid amounts to 0.04 per cent. (calculated as tartaric acid) and the volatile acid to 0.03 per cent. (calculated as acetic acid). The volatile ethers (calculated as ethylic acetate) amount to 130.6 parts per 100,000 parts of absolute alcohol in sample. The specific gravity is 0.9416. The evidence afforded by the taste and smell of the sample examined are in accordance with the claim of this brandy to be a genuine old spirit prepared from the alcoholic fermentation of grape juice. The flavour is exceptionally agreeable, and quite free from the rough taste that characterises an unmaturing brandy. The spirit is sold with a guarantee of its origin and of its being fourteen years old. We consider that it is eminently suitable for medicinal purposes and as a beverage. The brandy is introduced into Great Britain by Messrs. Wilson and Valdespino, Limited, of New London Street.

## NEW PREPARATIONS.

### FERRO-GLIDINE.

MESSRS. MENLEY AND JAMES, of Farringdon Street, London, have sent us samples of some new products. The first one, "ferro-glidine," is a preparation of iron in organic combination with pure vegetable protein. The recognition of the superior therapeutic value of iron in this kind of combination marks a distinct onward step in the pharmacology of that indispensable drug. The remedy is put up in the form of a large tablet packed in tubes of 20 and sold in boxes containing three tubes. Arsan is a further organic combination which presents arsenic with glidine, a non-irritant vegetable albumen obtained wholly from wheat and free from extractives. It has been found of value in syphilis and sleeping sickness. Lusan presents mercury in pure organic combination with pure wheat albumen. It is sold in tubes containing 25 tablets, and offers an excellent method of administering that drug to private patients. Bromoglidine is a similar preparation with bromine, and put up in the same form; its administration has been found most useful in epilepsy, especially in incipient cases of the malady, reducing the frequency of attacks, and in certain cases subduing them entirely.

## MEDICAL NEWS IN BRIEF.

### King's College Hospital Medical School Dinner.

THE annual dinner of the past and present students of King's College Hospital Medical School was held at the Waldorf Hotel on Friday, October 1st, 1909,

T. Hugh Smith, Esq., F.R.C.S., of Farningham, being in the chair. Of the hospital consulting and active staff, the following were present:—Dr. Burney Yeo, Dr. Ferrier, Prof. W. Rose, Sir W. Cheyne, Mr. Barrow, Dr. Dalton, Mr. Carless, Dr. Pritchard, Drs. Silk, Phillips, Whitfield, Playfair, Flux, Steen and Briscoe, Mr. Burghard and Mr. Cargill. Amongst the others present were Drs. Walters, Allfrey, Short, Lewis, Shuttleworth, Child, Essery, E. Wood, Val. Matthews, Davidson, E. Thurston, C.I.E., and the Secretaries, Dr. St. Clair Thomson, Mr. Peyton Beale, Dean of the School, and Dr. Wiltshire. There were 106 present. Mr. Hugh Smith proposed the toast of the evening, and in his remarks pointed out the immense amount of work which the student of the present day had to carry out in comparison with the student of past times, and also how much more strenuous his career had become. He also alluded to the fact that this was the first year of the school's existence as the Medical School of King's College Hospital. Previously it had been part of the Medical Faculty of King's College, London, but owing to the incorporation of that body with the University of London, the Medical School of the hospital, though still a school of the University, became independent. This was also necessary in view of the impending removal of the hospital to South London. He also alluded to the excellent examination results of the last few years. Dr. Walters, in replying, said that he was student in the year 1853, and he gave some idea of the work of the hospital and its staff at that time, mentioning the names of Farre, Todd and Partridge as great teachers. He said that he had no doubt whatever, when the hospital was rebuilt at Camberwell, and was able to expand its special departments, which were at present hopelessly cramped, its work would be better than it had ever been, and he felt sure that it would occupy the premier position amongst London hospitals and medical schools. Thanks were returned to the committee and secretaries of the dinner, which was pronounced to be most excellent both in kind and arrangement, and was voted a very great success by all present.

#### Royal College of Surgeons in Ireland—Students' Guide.

A GUIDE for Medical Students has just been issued by the Royal College of Surgeons in Ireland for the Session 1909-10. It gives full information for students studying for the conjoint diplomas of the Royal Colleges of Physicians and Surgeons, Dublin. The preliminary entrance examination will be held on Wednesday and Thursday, October 6th and 7th. The lectures and practical courses will commence on Friday, October 15th. The College accepts in lieu of the preliminary entrance examination the certificates of all examinations in general education recognised by the General Medical Council. During the summer recess the College of Surgeons School has been completely overhauled, and a considerable sum has been expended on improvements. The Guide, which is useful to intending students, will be sent post free on written application to the Registrar, Royal College of Surgeons, Stephen's Green, West, Dublin.

#### Death under Ether.

An inquest was held by Mr. Walter Schröder at Paddington, on September 25th, concerning the death of James Cross, aged 38, a farm labourer, of no fixed abode, who suddenly expired at St. Mary's Hospital after an administration of ether, and before a necessary surgical operation had been commenced. The jury found that the anæsthetic was duly and properly administered, and that death was due to misadventure.

#### Asiatic Cholera at West Hartlepool.

It is announced by the *Newcastle Chronicle* that, as the result of the bacteriological and post-mortem examinations, it has now been definitely ascertained that the death of the Swedish fireman removed to the Hartlepool Isolation Hospital from the Danish steamer *Sikkeborg*, was due to Asiatic cholera. The vessel having been disinfected in conformity with the Local Government Board's regulations under the supervision of the port medical officer, Dr. Biggart, and the inspector, and no further cases of

sickness having occurred on board, she has been released from quarantine.

#### The London Hospital Medical College (University of London).

THE following Entrance Scholarships have been awarded:—Price Entrance Scholarship in Science, value £120, Mr. J. Bostock. Entrance Science Scholarship, value £60, Mr. A. G. Winter. Entrance Science Scholarship, value £35, Mr. R. J. M. Love. Epsom Scholarship, value £126, Mr. H. G. Winter. Price Scholarship in Anatomy and Physiology (University Scholarship), value £60, Mr. J. R. Marrack (St. John's College, Cambridge).

#### The Royal University of Ireland.

THE following candidates have passed the First Examination in Medicine:—

Henry Alcock, Charles Bannigan, William W. Blair, Maud S. Budd, Patrick Cagney, Edward P. Carey, David M. Clements, William Deely, John J. Dowdall, Francis W. Doyle, B.A., Joseph Doyle, Sch., Owen J. R. Forde, Edward T. Freeman, Walter F. Hare, Herbert M. Jackson, Thomas Kennedy, Maurice B. King, Marie R. Lynch, William McElroy, Henry McGlaughlin, Mary C. McKenna, B.A., Edward U. MacWilliam, Edward A. M. Magennis, John Moonan, William A. Murphy, Gerald P. O'Donnell, Henry T. O'Neill, Samuel E. Picken, John E. Power, Robert L. Rea, Augustine K. Roche, John A. Sellars, Edward Tempamy, Catherine J. Timony.

The following may present themselves for the further examination for Honours in the subjects set opposite their names. Those qualified in two or more subjects may present themselves for the further examination for Honours in all:—

Patrick Cagney, Chemistry; David M. Clements, Physics; John J. Dowdall, Zoology; Joseph Doyle, Sch., Botany, Zoology, Chemistry, Physics; Thomas Kennedy, Chemistry; Maurice B. King, Physics; Edward U. MacWilliam, Botany and Physics; Edward A. M. Magennis, Zoology; John Moonan, Physics; Gerald P. O'Donnell, Zoology; Samuel E. Picken, Botany, Zoology; Robert L. Rea, Botany, Zoology, Chemistry, Physics; Augustine K. Roche, Chemistry; Catherine J. Timony, Zoology and Chemistry.

The following candidates have passed the Third Examination in Medicine. Those marked with an asterisk may present themselves for the further Examination for Honours:—

Upper Pass:—\*Crooks, Frederick, \*Hodnett, Joseph O., \*Johnson, John C., B.A., \*McConnell, Robert I., \*Mullane, Henry J. V., \*O'Hammon, Oriel J. O.

Pass:—Cogen, Maurice J., Cummins, Robert C., Davy, Thomas P., Fitzgerald, Gerald, Foley, David J., Lynch, Homer H. C., Lyons, John, Maguire, Thomas J. R., Millar, William M., Moren, Alfred J., Murphy, Mary A., O'Brien, William, O'Flynn, Joseph A., O'Keefe, Eileen M., Osburne, John C., Patrick, Joseph, Prendiville, Joseph, Rishworth, Walter N., Rothwell, Thomas G., Smyth, William J., Twigg, Francis J. D., White, Patrick W., Wilson, William.

#### Apothecaries' Hall of Ireland.

At the meeting of the Apothecaries' Hall of Ireland the following were elected Examiners for the ensuing year:—

Surgery—Professor Conway Dwyer, Sir Thomas Myles.

Medicine—J. M. Day, J. O'Donnell.

Midwifery—R. H. Fleming, R. J. White.

Ophthalmology—E. Magennis, R. J. Montgomery.

Pathology—J. L. Keegan, R. J. Rowlette.

Materia Medica—J. D. Crinion, W. Fottrell.

Hygiene—Sir Charles Cameron, H. F. Powell.

Materia Medica—J. D. Crinion, Seymour Stritch.

Pharmacy—F. G. Adye-Curran, E. F. Hanrahan.

Anatomy—Professor E. P. M'Loughlin, P. J. Fagan.

Physiology and Biology—Professor D. J. Coffey,

William O'Kelly, J. Knott.

Chemistry—Professor Hugh Ryan, J. J. O'Sullivan.

Physics—Professor Hugh Ryan, B. Burke Kennedy.

## NOTICES TO CORRESPONDENTS, &c.

Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

### SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs 15.12. Messrs. Dawson and Sons are our special agents for Canada.

### ADVERTISEMENTS.

For ONE INSERTION:—Whole Page, £5; Half Page, £3 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

**SUBURBAN PRACTITIONER.**—The publication of a change of address in a medical journal by a medical man, whatever his position, seems to us an undignified proceeding. In the case quoted the gentleman referred to is an official of the Royal College of Physicians of London, which renders the incident still more surprising. We quite agree that were an ordinary practitioner to do a corresponding thing in a lay newspaper he would in all probability be promptly "hauled over the coals."

**H. J. PARSONS.**—Your general impression is right, but we must remind you that the Medical Defence Union, at any rate, puts at the head of its description "Established to promote honourable practice." It is, of course, less easy to advance the right than to attack the wrong; but, at the same time, it is reassuring to find an association of medical men making a formal avowal of a set policy of the kind.

A CORRESPONDENT writes complaining that he is much troubled by patients who ask questions over the telephone, and that he finds many of them in that way reduce the number of consultations and visits. If a medical man gives substantial advice over the telephone, he is entitled to charge for it. It would be well to let patients know that such would be the case. Some medical men leave the answering of telephone to some responsible person in the household, with instructions as to answering special calls.

### PURE MILK.

A FARMER close to a town near Glasgow recommends his milk thus. He says: "I send a sample of my milk to be analysed every six months, and the chemist never has any fault to find with it."

**MR. SANDOW AND THE "TIMES."**—A correspondent asks whether an article which occupied half a page in the *Times* of September 29th, which it states was "prepared in the interests of readers of the *Times*," is to be taken as an editorial, or as an advertisement? We can only refer our correspondent to the manager of the *Times* and Mr. Sandow.

**HEALTH IN INDIA.**—"Civil Servant" would do well to follow the example of sensible Europeans, who may form the society of the station to which he is ordered. There can be no doubt that into an Indian dietary alcohol in any form should be very sparingly admitted, if admitted at all.

**MATER.**—The deformity is usually curable by operation. Consult your family doctor, and he will if necessary call in a specialist.

## Meetings of the Societies, Lectures, &c.

### WEDNESDAY, OCTOBER 6TH.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.)—4 p.m.: Mr. M. White: Clinique (Surgical). 5.15 p.m.: Lecture: Mr. M. Yearsley: The Nose and Ear in School Medical Inspection.

### THURSDAY, OCTOBER 7TH.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.)—4 p.m.: Sir Jonathan Hutchinson: Clinique (Surgical). 5.15 p.m.: Lecture: Mr. J. Clarke: A Series of Abdominal Cases.

**NORTH-EAST LONDON POST-GRADUATE COLLEGE**, (Prince of Wales's General Hospital, Tottenham, N.)—4 p.m.: Mr. J. Bland-Sutton: Hernia of the Uterus in Men and Women. (Opening Lecture.)

### FRIDAY, OCTOBER 8TH.

**ROYAL SOCIETY OF MEDICINE** (20 Hanover Square, W.)—Clinical Section: 8 p.m. Cases by Dr. Rolleston, Mr. Albert Carless, Mr. James Sherren, Dr. Finzi and Dr. Ernest Shaw. Demonstration: Dr. Bayley: Demonstration of the Treponema Pallidum in Syphilitic Lesions; of the Spirocheta Dentium in Carious Dentine; and of the Spirocheta Refringens in Balanitis. Papers by Sir Dyce Duckworth: (1) A Case of Gout with Tophaceous Deposits in Mahomedan, with photographs; (2) A Case of Gout with Uric Tophi in a Boy, aged 14. Dr. Herringham: Two Cases of Pneumonia with considerable Displacement of the Heart simulating Pleural Effusion.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.)—4 p.m.: Mr. S. Stephenson: Clinique (Eye).

### MONDAY, OCTOBER 11TH.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.)—4 p.m.: Dr. S. E. Dore: Clinique (Skin). 5.15 p.m.: Dr. Harry Campbell: "Treatment of Neuralgia."

**MEDICAL SOCIETY OF LONDON**—8 p.m.: General meeting. 8.30 p.m.: Incoming President's address; Paper on "Two Cases of Perforation of the Small Intestine," by Mr. Hugh Lett.

### TUESDAY, OCTOBER 12TH.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.)—4 p.m.: Dr. Essex Wynter: Clinique (Med.). 5.15 p.m.: Dr. E. C. Hort: "Rational Immunisation from a Practical Standpoint."

## Appointments.

**BRUCE, T. H., M.D., C.M.Glasg., F.F.P.S.Glasg.**, Regius Professor of Anatomy in the University of Glasgow.

**CARSON, J. T., M.B., Ch.B.Edin.**, Junior House Surgeon at the Bolton Infirmary.

**EDWARDS, A. H., M.B., F.R.C.S.**, Dispensary Surgeon, Western Infirmary, Glasgow.

**EMMERSON, HERBERT, M.R.C.S., L.R.C.P.Lond.**, Honorary Ophthalmic Surgeon to the Chesterfield and North Derbyshire Hospital.

**GORDON, A. BRUCE, M.B., Ch.B.Edin.**, Resident Medical Officer at the London Temperance Hotel.

**HOARE, E. F., M.D., Ch.B.Liverp., L.S.A.**, Deputy Medical Officer and Vaccinator to Daisybrook Schools by the West Derby Board of Guardians.

**MARNOCK, J., M.B., C.M.Aberd.**, Professor of Surgery in the University of Aberdeen.

**ROBERTS, ERNEST T., M.D., C.M. Edin.**, Principal Medical Officer for the Inspection of Children in the Glasgow School Board.

**SHEPHERD, H. F., L.R.C.P. and S.Edin., L.F.P.S.Glasg.**, Certifying Surgeon under the Factory and Workshop Act for the works of the South Shields Gas Company, at South Shields, in the county of Durham.

**THIRNE, W., M.D.Edin.**, Medical Officer for the Workhouse and the First District, and Public Vaccinator for the First District, of the Barnet Union.

**NICOL, JOHN WILLIE, M.B., C.M.**, Physician to the Wards for Skin Diseases, Western Infirmary, Glasgow.

**TOMKINSON, I. GOODWIN, M.D.**, Physician to the Skin Dispensary, Western Infirmary, Glasgow.

**YOUNG, DR. ROY F.**, Extra Dispensary Surgeon, Western Infirmary, Glasgow.

## Vacancies.

**Sussex County Hospital, Brighton.**—House Surgeon. Salary £120 per annum, with board and residence in the Hospital with washing. Applications the 5th day of October next, addressed to the Secretary. The election will take place on the 20th October, 1909.

**The Hospital for Sick Children, Great Ormond Street, London, W.C.**—A House Surgeon. Appointment for six months. Remuneration £30, with board, washing, and residence in hospital; also Anaesthetist (honorary). For further particulars see advt.

**Brighton, Hove, and Preston Dispensary (Northern Branch).**—Resident Medical Officer. Salary £160 per annum, with furnished rooms, coals, gas, and attendance. Applications to the Assistant Secretary, 113, Queen's Road, Brighton.

**Nottingham General Dispensary.**—Two Assistant Resident Surgeons. Salary £160 each per annum, with apartments, attendance, light, and fuel. Applications to C. Cheesman, Secretary, 12, Low avement, Nottingham.

**Birmingham General Dispensary.**—Resident Surgeon. Salary £200 per annum, including cab allowance. Applications to Ernest W. Forrest, Secretary, 32, Union Street, Birmingham.

## Births.

**HARMAN.**—On September 30th, at 108 Harley Street, London, W., the wife of N. Bishop Harman, F.R.C.S., of a daughter.

**MEAGHER.**—On September 25th, at Haulbowline, the wife of Fleet-Surgeon Edward Meagher, R.N., of a daughter.

**VARVILL.**—On September 29th, at 1, Sussex Place, Southsea, the wife of Bernard Varvill, B.A.M.C., of a son.

## Marriages.

**DICKSON—RHODES.**—On September 29th, at St. Leonard's, Bridgnorth, Louis Edington Dickson, M.D., B.S., son of S. J. E. Dickson, solicitor, of Chester, to Margaret Helen, only daughter of the late William Rhodes, M.R.C.S. and L.R.C.P., and Mrs. Rhodes, of Bridgnorth.

**DOUGLAS—MARTIN.**—On September 30th, at St. Peter's Church, Jersey, Archibald C. B. Douglas to Hilda, daughter of J. H. Martin, M.D., of Thornhill, Jersey.

**GIBBS—HARPER.**—On September 28th, at Heanton-Punchardon, North Devon, Stanley Rider Gibbs, M.R.C.S., L.R.C.P., younger son of the late Joseph Huoks Gibbs, to Margaret Ellen, daughter of the late Dr. Joseph Harper, of Barnstaple.

## Deaths.

**ROBINSON.**—On October 2nd, at Bellevue Cottages, Whitehead, co. Antrim, Ireland, Dr. William Robinson, late of Falcon Road, Battersea, London aged 49 years.

**SMITH.**—On October 1st, at 5 Stratford Place, London, W., Sir Thomas Smith, Bart., K.C.V.O., F.R.C.S., Honorary Surgeon to H.M. King, aged 76. No flowers, by request.

## NOTES AND COMMENTS.

### **The Passing of Honorary Staffs.**

IF we read aright the signs of the times, the day is at hand when there will be no more honorary medical attendance at the hospitals. If medical residents and nurses and secretaries and other officials and servants are to be paid for their services, why should not the medical men also be compensated for the skill, time, and labour which is required of them? In some institutions a fee of £50 or £100 is actually paid to members of the honorary staff, but the fact is usually carefully kept in the background, and the payment entered as a lecturing fee or travelling expenses. Indeed, it is not easy to imagine any logical scheme of philanthropic medical relief which does not provide adequate payment to the medical men upon whose skilled work the existence of the hospitals depends. Nowadays the stress of professional competition falls heavily on the younger men, who are more handicapped than ever in the struggle to obtain an adequate income. Before another generation is past the reaction will probably have set in, and the honorary hospital appointment will have vanished into the limbo of forgetfulness, along with other gratuitous services that have been foisted upon a humane and easy-going profession. In point of fact, the change is even now taking place.

### **Barry Pays its Hospital Staff.**

THE hospital problem has been worked out at the Welsh town of Barry in more ways than one. Some time ago the townsfolk determined that they would have their own rate-supported Accident and Surgical Hospital, a scheme that was duly carried out. The medical staff was purely honorary and selected from local medical men. Some time later the remainder of the local practitioners requested to be put on the rota, and the whole question was referred to the British Medical Association. In the upshot the hospital committee has recommended the Town Council to agree to the employment of the whole of the doctors of the town, in batches of four, each to be paid £20 per annum. This will involve an additional expenditure of about £350 from the rates for the maintenance of the hospital. It is to be hoped that the Barry Council will maintain its high standard of wisdom and independence by resolving to pay its medical men for their services. To furnish a full hospital organisation out of the rates for the benefit of its citizens and then to tax the medical profession for its maintenance would be to revert to the bad old traditions whereby the unfortunate medical man is the instrument of all kinds of vicarious charity. Of late, however, the spirit of collective defence has somewhat stimulated

the wisdom of the dove, and medical men are beginning to realise the truth of the old maxim that the labourer is worthy of his hire.

### **Death of a Medical M.P.**

THE sudden death of Dr. George J. Cooper, Member of Parliament for a London constituency, deprives the medical profession of an active representative in the Commons. His end was due to a stroke of apoplexy, and while actually in the lobby of the House the attention of Sir Walter Foster was drawn to him by the peculiar flush upon his face. There can be little doubt that the untoward result was due in great measure to the strain put upon members of Parliament by a protracted and arduous session. Dr. Cooper carried on a large private practice, but his attendance in the House was punctual and practically unflinching. He was one of the few medical men in the Commons who really represented the interests of his profession. The record of his public work includes service on the London County Council, of which body he was a member from 1899 to 1906, and retired only upon his election to the House of Commons. His death has left a gap in medical representation that we can ill afford. His work has been well done, and it may be said of him that his life was sacrificed to duty, and he died like a soldier, fighting in the forefront of the battle.

### **The Need of Medical M.P's.**

THE record of self-sacrifice and of achievement left by Dr. Cooper will not be lost if it draws general attention to the need of medical men in Parliament. Apart from purely professional interests, there are many ways in which an enlightened medical member may do yeoman service to the public weal. Think for a moment of the many social conditions and circumstances, such as housing, water-supply, drainage, emigration, education, the purity of food, air and water, and the thousand-and-one things in which modern scientific medicine is more or less directly concerned. In all these matters the advice of the medical member may be absolutely indispensable to keep his lay brethren on the right track. As regards the profession, it is clear that more medical men are wanted in the House, and they should go there charged authoritatively with the defence of professional interests. As a suggestion pure and simple, why should not the British Medical Association maintain a medical member, regardless of his party politics? Would it be possible for the Medical Defence Union to send a representative to the Commons? Or, failing that, would it be feasible for a combination of protective organisations conjointly to pay the expenses of a member of Parliament?

### Why Help is Needed.

THERE are various reasons why active monetary support is needed for anything like adequate representation of medical men in Parliament. In the first place, as a rule, the medical man has to make his living by the practice of an exacting and laborious profession. If he lives in the country, it is only possible for him to attend to his duties in the House by practically abandoning his medical work. If in town, he can attend only by an expenditure of personal energy that lays an undue tax upon his constitution. For these and other reasons, it is fairly self-evident that if the medical profession resolves upon the necessity of parliamentary representation in its collective capacity, that end can be attained only by the subsidy of men in the profession. Under present conditions the medical man in Parliament is apt to become so swallowed up in politics that purely professional matters have little interest for him. Fortunately there are exceptions, such as the late Dr. Cooper and the late Dr. Hutchinson, and the present Sir W. J. Collins. In the Upper House Lord Lister has upon occasion exerted decisive influence, and some day we hope the counsels of the non-elective chamber may be strengthened by a further accession of medical peers.

### The Press and Quackery.

At Shoreham, last week, an inquest was held into the circumstances attending the death of an elderly man from blood-poisoning, which it was alleged had supervened upon the application of a "corn cure" to one of his toes. The medical attendant stated that he found ulceration which had extended into a joint. The toe was amputated, but gangrene of the foot followed, with acute and fatal septicæmia. The man was in bad health, and the "corn cure"—a preparation containing salicylic acid—was strongly corrosive, and capable of extensively damaging tissues in an elderly and unhealthy subject. This case would barely deserve notice but for the fact that in the reports in the local papers the name of the "corn cure" is suppressed. It would be interesting to know whether it is advertised without any warning of its dangers in any of these newspapers.

## LEADING ARTICLES.

### THE DAY OF THE PROVINCIAL MEDICAL SCHOOLS.

THE curious chaos of conflicting interests whereby the candidate for medical qualification is faced with many portals of admission, has resulted in various tides of popularity, now in this and now in that direction. The General Medical Council, in the half-century of its existence, has ensured a fair general standard of examination knowledge in all cases. There is reason to believe, however, that in some instances the requirements of the examiners are abnormally high, and the extent and technical nature of their questions such as it would be impossible to answer, except by students crammed for the occasion with undigested masses of other men's knowledge. The University of London not only sets an abnormally high standard, but also imposes a matriculation with conditions that must infallibly frighten off the timid and exclude many sound candidates. So far as the London medical schools are concerned, the lack of a university

degree on reasonable terms has given a great advantage to the universities in other parts of the Kingdom. Parents and students have recognised more and more generally the fact that, with an equal expenditure of time, labour and money, it is possible to get a medical degree in a local university which equips the possessor for the battle of professional life more efficiently than the mere diploma of any College or Hall, no matter how ancient or distinguished. Moreover, a graduate of a university has a voice in the management of his own affairs, whereas the diplomate of the lower station is absolutely excluded from taking any part in the government of the corporation to which he belongs. The college takes the money, gives him a diploma, and thenceforth has no further concern with his welfare or with the protection of his interests. The result of so selfish and antiquated a policy of class government must sooner or later be the abandonment of the qualifying bodies which cling to mediæval traditions for the healthier and more practical organisation of the modern provincial university. Comment of this kind may seem harsh, but fair words will not fill depleted class-rooms, and it is in the interests of the diploma-granting corporations themselves that candid criticism is demanded. The key to the present situation is probably to be found in the medical degree granted on reasonable terms, and the best chance of survival of the ancient Colleges and Halls will be in co-operating with the universities in a conjoint degree. In other words, the stress of evolution in medical education is inevitably tending towards the only rational solution of its complex problems—namely, a one-portal qualification. The popularity of the provincial universities has not been lessened by the indifference shown by the colleges to the interests of their *alumni*. The fellows of the Royal College of Surgeons of England have steadily refused the members any voice in the government of the corporation. The Royal College of Surgeons of Edinburgh similarly excludes its licentiates, while it refuses to institute a membership diploma which would place those licentiates on a footing of equality with the diplomates of other colleges who are their competitors in professional life. All the diploma-granting corporations nominate their representatives on the General Medical Council, where they form the majority. It may be safely said that during the fifty-one years of the Council's existence the voice of these corporation nominees has only on rare occasions been raised in the interests of the profession generally. If the Colleges and Halls wish to regain their waning popularity, one of the most promising steps in that direction would probably be to hand the election of the college representatives on the General Medical Council to the general body of their diplomates, regardless of rank. Another vital point would be co-operation with local universities in the granting of degrees and the alteration of constitution so as to make their government democratic instead of oligarchic. If some such reforms were effected the various medical schools would be relieved of the handicap of accidental and extraneous attractions, and the competition of the

many corporations would be narrowed to a basis of pure academic merit, a result that would be hailed with delight by many to whom these ancient bodies are endeared by personal affection, no less than they are revered for the traditions of their noble and time-honoured history.

### CURRENT TOPICS.

#### Christian Science at the Church Congress.

IN its relation with disease and suffering, the first function of religion is to bring into the sick room fortitude, patience and consolation. No enlightened Christian sect attempts nowadays to go beyond this, and, least of all, to undertake the treatment of disease in imitation of the thaumaturgy of the Middle Ages. Certain small parties of clerics of various denominations, including the Church of England, have, however, latterly displayed an inclination to emulate the example of the Christian Scientists in attempting, by spiritual means, the cure of diseases of the nature of which they confess their complete ignorance. In view of this fact, Mr. Stephen Paget has put the Church under an obligation by his trenchant exposure of Christian Science, in his paper at the Congress on Thursday last. In preparing his book on Christian Science, Mr. Paget inquired into the alleged healings of grave organic diseases, and he found not one authenticated case. He pointed out that Christian Science does not publish her failures. He had in his possession a long list of her killed and wounded; he wished that it could be nailed to the doors of all her churches. Seeing the gross and shameful malpractices of Christian Science, the long trail of pain and of death that she left behind her, her impudent concealment of all her failures and worse than failures, and her mad resolve never to acknowledge any difference between backache and spinal caries, between functional paralysis and organic paralysis, between indigestion and cancer of the stomach, between pain in the breast and cancer of the breast, and her frequent cruelty, especially to small children—seeing all these abominations, they ought to prevent even the faintest shadow of them from falling across the Church. It is satisfactory to note that not one voice was raised from among the large audience to combat or protest against Mr. Paget's scathing indictment.

#### Tuberculosis in Army, Navy, and Post-Office.

IN answer to a question in the House, last week, it was stated, on behalf of the Postmaster-General, that in the year 1908 90 men and 20 women were discharged from the Post Office suffering from tuberculosis. At the same time it was admitted there was no official arrangement to provide them with treatment, but every established official retiring on account of ill-health was entitled either to a pension or a gratuity. The same lamentable want of special provision for discharged consumptives prevails in the military and naval services. Now, if the State be serious in its endeavours to solve the great national problem of how to extirpate tuberculosis, surely here is an opening which appeals to the moral as well as the economic con-

science. Why should not the Government accept the responsibility of caring for those who have contracted consumption during their term of service, just as it would for disability, due to some stray bullet or accidents arising from occupation? To turn out into the streets, as it were, a regiment of consumptive soldiers, sailors and post office employees is to flout Providence and to run counter to modern medical teaching. By the very circumstances of the case many of these unfortunate sufferers will be unable to make a living, and so will be under the conditions of poverty most favourable to the spread of their malady. Surely it is the bounden duty of the State, in view of our present scientific medical knowledge of tuberculosis, to provide special treatment for all her servants disabled by that universal and preventable scourge.

#### The Mummified Remains at Stamford.

FURTHER developments have arisen in connection with the recent discovery at Stamford, on the site of the Black Friars' Monastery, of a leaden coffin containing embalmed human remains. Some weeks ago we noted the unearthing of an ancient coffin at Stamford, on the site of an old Priory, and the subsequent burial of the body in a field. The sequel shows a more reverent treatment of the remains, for it is announced, on the authority of the *Times*, that the Home Secretary has ordered the re-interment of the remains in consecrated ground, and permission has been granted for a medical man to examine the body. Dr. G. Boyd, the Medical Officer of Health for Stamford, has ascertained that the remains were those of a man. The flesh was in an almost perfect state after having been buried for over 500 years, and the features were easily distinguishable as those of an elderly priest. It was decided that the body is that of John Staunford, who was prior of the Black Friars at Stamford in the latter part of the fourteenth century. The remains were afterwards replaced in the leaden shell, which was enclosed in a wooden coffin, and removed to St. Augustine's Roman Catholic Church at Stamford, where a *requiem* service was held. Later the body was reinterred in a grave specially purchased in the portion of the local cemetery reserved for Roman Catholics. A paper was placed inside the coffin recording the incidents of the discovery and re-interment of the remains.

#### Health Visitors in Aberdeen.

CERTAIN allegations made by Trades Unions as to defective qualifications of health visitors in Aberdeen have served to elicit an official statement demonstrative of the admirable work that has been carried out by these ladies since the first was appointed in 1903. They have all been carefully selected, not only with regard to training and certificates, but also with regard to possession of tact, sympathy and address. A good general education has been deemed desirable, and it has been recognised that a woman of refinement is needed to win the confidence and respect of the poor mothers she strives to influence. Although there has been difficulty in obtaining visitors with previous experience—the sphere of work being so

new, and Aberdeen being one of the first towns in Scotland to enter upon this work—there has been no difficulty in securing the services of women with the highest personal and technical qualifications—trained nurses, mostly with maternity hospital experience. In Aberdeen, as throughout the whole Kingdom, there has been within recent years a remarkable reduction in the mortality at every period except the infant period of life; but this latter has steadily decreased since the appointment of health visitors. Here, as everywhere, the fact is made plain that the waste of infant life is mainly due to the ignorance—often the perfectly innocent ignorance—of the mothers. They have never been taught, they have no means of learning the simple rules for maintaining their own health and that of their babies; they destroy their infants, in most cases, by bad feeding alone. In Aberdeen there now exists a "Mothers' and Babies' Club," where instruction and help is provided in the care and feeding of infants, the health visitors and the Health Department co-operating with the Committee in carrying on this good work. Infantile mortality is, of course, a measure of the injury inflicted upon the constitutions of many of those that survive after going through an ordeal of malnutrition and disease. To diminish waste of infant life is thus, at the same time, to ensure improvement in the national physique.

#### 'Athletics and Health.

EARLY in the present year some debate arose as to the effect of athletics, in particular, long-distance running, on health, certain rather hasty members of the medical profession having thought fit to pronounce public condemnation. The discussion, therefore, at the Belfast meeting of the British Medical Association is of special interest, since the men taking part therein—such as Dr. Tyrrell Brooks, of Oxford, and Dr. Clement Dukes, of Rugby—unlike many of those who signed the famous condemnation, are specially qualified by experience to speak with authority. While, therefore, as Dr. Dukes shows, there are certain easily avoided risks in long-distance running, on the whole the dangers arising from athletic exercises of all kinds are far more than counterbalanced by the advantages. As regards the risks, they are, after all, slight, and seldom, if ever, is there any permanent injury left. We are glad to note that some of the speakers criticised the attempt to substitute physical exercises for games and competitions. "The more hazardous the game," says Sir James Barr, "the better for the development of the character of the individual." We are not sure that this dictum is entirely true, since it seems to justify a substitution of brutality for skill and combination, such as has taken place in the American development of football. The debate as a whole is a triumph for the existing vogue of athletics, and we must express our satisfaction that grandmotherly persons with fads have not succeeded in depriving our youth of one of its most valuable institutions.

#### Water and Sewage of Dublin.

It was only last week that we had to comment on the extraordinary muddle in the investigation

of the Clontarf outbreak of typhoid fever. At the present time the city of Dublin is subjected to two grave dangers—the breakdown of the drainage system and a shortage in the water supply. It is only a few years since a very large sum of money was spent in establishing a new main drainage system, designed to obviate the necessity of using the Liffey as an open sewer. A week or two ago it was discovered that one of the main drains of the south side of the city was quite blocked with a deposit of several thousand tons. As a result, while the process of cleansing is going on, the sewage is discharged into the Liffey in its course through the city, and the odours during the recent dry weather have been all but intolerable. Whether this failure was due to an essential flaw in the original plans of the main drainage system, or to culpable neglect on the part of those responsible for the supervision of the system in work, we are at present unable to state. While the citizens are smarting under this head, they are threatened with another, even more grave. It is stated that the water supply is running dangerously low, considerably more than half the normal reserve having been exhausted. At present, at the normal rate of consumption, there is barely water to last two months. Of course, it may be pointed out that we are not likely to have another month's dry weather, but it takes a considerable time for rainfall to make itself felt in the Roundwood reservoir, and the margin of time is becoming narrow.

#### Uncleanly Heads in School Children.

THE Medical Officer of Barnsley, Dr. Sadler, has recently submitted to the Education Committee a report in which he deals with the subject of "Uncleanly Heads in School Children." Out of 3,794 children examined he found 3,297 had decayed teeth, 2,238 had something wrong with their nose and throat, and 1,170—of whom 974 were girls, had dirty heads and skin diseases, and of the whole number only 117 were badly nourished. 1,106, nearly one-third, had defective vision, 243 some form of ear disease and 419 defective hearing; the heart was defective in 188 cases and the lungs in 252 cases, 181 were suffering from some form or other of tuberculosis, 168 showed signs of rickets. One child had scarlet fever, one mumps, twelve ringworm, one chicken-pox and 27 scabies. Amongst the girls dirty heads, that is to say, heads infected with pediculi, were the exception rather than the rule. Dr. Sadler remarked that the proportion of girls with dirty heads was so large that it seemed to him that possibly the simplest plan would be to institute separate desks for all girls with clean heads. In the percentage figures, it is probable that in any given class there will be found enough girls with clean heads to fill at least one form, and he thought it might be better to make it an honour to sit on the clean form, rather than make it a disgrace to be separated in class-rooms as dirty. The question of cloakroom accommodation is a difficult one, but Dr. Sadler entertains no doubt that children going to the elementary schools from careful homes, and with clean heads, do actually acquire vermin by putting their caps or hats on the pegs which had been used for the

caps or hats of dirty children. It is, perhaps, inadvisable to suggest a system of lockers for so large a number of children as are congregated at any given school, but it does seem feasible that each child should have a separate peg labelled with its name, and that it should be a punishable offence for a child to put its hat or cloak on the peg of another. This observation coincides with the experience of many hospital physicians who have to deal with out-patient children from the slums. Few heads indeed, if examined carefully under such conditions would be found free from ova pediculi. Under the Children Act the medical officer of health is invested with compulsory powers in the treatment of that class of case.

## PERSONAL.

THE PRINCESS OF WALES visited on Saturday afternoon the National Hospital for the Paralysed and Epileptic, Queen Square, Bloomsbury, and received a number of purses containing money given to and collected for the Jubilee Fund.

DR. MEACHEN, at the Institute of Hygiene last Thursday, spoke on the question, "What Shall we Eat?"

MR. E. C. ROBINSON, in his book, "In an Unknown Land," describes how he met Peary when the *Roosevelt* put in for whale meat.

SIR JOHN BYERS, M.D., has been elected President of the Natural History and Philosophical Society of Belfast for a second term of office.

LORD BRASSEY, Lord Warden of the Cinque Ports, opened the newly-erected General Hospital and Seamen's Infirmary at Ramsgate on last Thursday afternoon.

PROFESSOR ALEXIS THOMSON, recently appointed to the chair of Surgery in Edinburgh University, delivered his Introductory Lecture to his students in the M'Ewan Hall.

AT the annual meeting of the British Dairy Farmers' Association Lord Belper occupied the chair, and moved the adoption of its exceedingly brief and businesslike report.

LADY ADELA MOUAT, widow of Surgeon-General Sir James Mouat, Honorary Surgeon to Queen Victoria, and head of the General Field Hospital at Sebastopol, died on October 7th.

PROFESSOR HENRY KENWOOD will deliver a public introductory lecture at the Chadwick Training Course in School Hygiene, University of London, on "What Hygiene Demands of School Teachers."

LORD JUSTICE FLETCHER MOULTON was recently entertained at dinner by the medical profession of Leeds, where he had delivered the Opening Address of the University School of Medicine in the morning.

We regret to learn that Sir William Thomson, C.B., Surgeon-in-Ordinary to the King and a past President of the Royal College of Surgeons in Ireland, is lying seriously ill at his residence, St. Stephen's Green, Dublin.

ON October 6th the Lord-Lieutenant of Norfolk (the Earl of Leicester) presided at St. Andrew's Hall, Norwich, over a large and influentially attended county meeting, called in support of the extension fund of the Norfolk County Hospital.

It is announced that Dr. Shiwopiszev, of the Russian Government Lymph Institution at Orel, last week laid a wreath on the tomb of Jenner, the discoverer of vaccination, in Bristol parish church. His journey from Russia was made for the purpose.

AFTER many experiments, Dr. Goodall, of the Middlesex Hospital, has found that, as a general rule, cultured and educated people prefer chocolate-coloured foods; uneducated people like yellow-coloured foods; children of all classes have a fondness for pink foods.

AT the annual meeting of the Royal Academy of Medicine in Ireland, held on Friday last, Sir Charles Ball, Regius Professor of Surgery in the University of Dublin, was elected President of the Academy. The results of the remaining elections will be found in another column.

THE DEAN of the Medical Faculty of the Liverpool University (Dr. Monsarrat) presided on October 5th in the Arts Theatre at the opening of the medical session, when the Introductory Address was delivered by Mr. Charles A. Ballance, M.V.O., M.S., Surgeon to St. Thomas's Hospital, London.

LADY DUDLEY, the wife of the Governor-General, delivered an address in Brisbane strongly advocating the extension to the country districts of the movement for providing trained nurses for the poorer class of patients. Since it was heard much interest has been aroused in the subject.

THE PRIME MINISTER is to be asked by Sir William Collins whether he has received any communications from the medical schools of London respecting the standard of the medical examinations for London University degrees, and what action the Government propose to take regarding them.

IT is announced that the Glasgow University and Glasgow Victoria Infirmary are each to benefit to the extent of £10,000 from the estate of the late Dr. Robert Pollok. His will contained no bequest, but separate writing was found suggesting that his sisters, the residuary legatees, should give £10,000 for the endowment of a special ward in the infirmary and £10,000 for the endowment of a University lectureship in materia medica.

FLEET-SURGEON C. G. MATTHEW, C.B., who has been placed on the retired list at his own request, was recently acquitted by a court-martial of charges arising out of some unpleasantness which occurred with Commander R. Walters, of the *Fisgard* training establishment. Fleet-Surgeon C. G. Matthew joined the Service in February, 1889, and was present at the bombardment and capture of the Sultan of Zanzibar's palace.

F. M. SANDWITH, M.D., Gresham Professor of Physic, will deliver four lectures on "Some Medical Aspects of the Poor-law Commission," on Tuesday, October 26th, Wednesday, October 27th, Thursday, October 28th, and Friday, October 29th, 1909. The lectures for the present term will be delivered at the City of London School, Victoria Embankment. The course is free to the public, and begins each evening at 6 o'clock.

# A CLINICAL LECTURE

## ON

### DECHLORINATION IN THE TREATMENT OF CHRONIC BRIGHT'S DISEASE.

By J. STEWART FOWLER, M.D.Edin., F.R.C.P.,

Physician to the Royal Hospital for Sick Children, Edinburgh.

GENTLEMEN,—The subject to which I wish to direct your attention this afternoon is the treatment of chronic Bright's disease by dechlorination. By dechlorination is meant the restriction of the amount of sodium chloride in the diet to the smallest possible limits. This method of dieting was introduced by Widal in 1903 as a means of treating what is one of the leading symptoms of chronic Bright's disease, viz., dropsy, and in a number of cases it gives extremely good results. The class of case for which it is most suitable is chronic parenchymatous nephritis associated with dropsy, and it will not infrequently be found that patients who are bed-ridden from oedema, which may have resisted all ordinary treatment with hot packs, diuretics, purgatives, etc., respond quickly to a salt-free diet, copious diuresis setting in, the oedema vanishing and remaining more or less permanently absent so long as the salt-free diet is adhered to.

I propose first to explain the theory of dechlorination; second to cite some illustrative cases; third to describe the method as it is carried out in practice.

Common salt is one of the most widely distributed substances in Nature. It is contained in every animal and vegetable tissue; all the organs of the body are bathed in saline fluid. It is necessary for the health of the cells that the concentration of the saline fluid by which they are surrounded and permeated should remain fairly constant. The so-called "physiological salt solution" is neutral towards the most delicate structures, whereas weaker or stronger solutions are harmful. We utilise this fact daily in employing saline injections either into the bowel or subcutaneously.

It has long been known that in many forms of nephritis the excretion of salt by the kidneys is interfered with. This used to be looked upon as secondary to the existence of oedema, the salt being retained in the body to form an isotonic solution in the water in the tissues. Widal's observations, however, show that the reverse is the case. The primary event is the failure of the kidneys to eliminate salt, and the dropsy is caused by the retention of water in the tissues in order to hold it in isotonic solution, or, in other words, to maintain a constant osmotic pressure. Proof of this will be given by the charts which I shall show.

The quantity of salt which a healthy man excretes depends on the amount he eats. The amount eliminated daily is not a measure of the daily needs of the organism, because in the fasting condition the daily excretion of sodium chloride is only about .6 gramme. This, therefore, represents the total amount actually lost by the tissues, and which requires to be supplied in the food. Salt is eliminated by the bowel and skin as well as by the urine, but unless there is profuse sweating or diarrhoea the quantity got rid of by the first and second channels is negligible. Normally, the urinary chlorides are about 95 per cent. of the total, and reach, on the average, 15 to 20 grammes daily. In an ordinary mixed diet there is about 17 grammes of salt, the great part of which is added salt. A

diet sheet can readily be constructed, the constituents of which yield abundant calories, and contain proteid, fat, and carbohydrate in the normal amounts, which yet contain only 1.5 to 2 grammes of salt—more than enough to replace the daily tissue loss—and there is no question that on a diet of this kind health may be maintained for a long, if not indefinite, period.

Contrary to what might be anticipated, privation from salt (as is involved in such a diet) is not injurious to health. The practice of eating salt, though almost universal, and not restricted to the human species, appears to depend solely on custom and on the gratification of the appetite. The infant, during its period of greatest growth, requires no more salt than the gramme and a half which is yielded by the mother's milk. Among certain races, notably pastoral and nomadic peoples, salt does not enter into the dietary, and, on the whole, it may be said that the desire for salt is less, both in man and animals, in proportion as flesh preponderates over vegetable in the diet. Historical instances of disease caused by lack of salt do not stand scrutiny. It is said that during the siege of Metz the troops suffered from this cause, whereas they obtained plenty of salt from a salt spring which was used to prepare their food, but had no powdered salt with which to disguise the repugnant taste of the flesh of the famine-stricken horses to which they were reduced. (Widal.) Salt, therefore, is not so much a necessity as a luxury, and a salt tax, though one of the oldest of fiscal exactions, in so far conforms to the theories of modern political economy.

Normally, the organism is in a state of chloride equilibrium, the amount excreted equalling that ingested. When a healthy subject is put on a salt-free diet, he for two or three days thereafter eliminates more chloride than he receives, then the chloride balance is established. When salt is restored to the food the amount excreted does not at once rise; for two or three days some is retained in the tissues, and then equilibrium is re-established. Variations in the amount of chloride in the body are accompanied by variations in the amount of water. Retention of chlorides is associated with diminished flow of urine and increase in weight; elimination of chlorides with diuresis and a fall in weight. The amount of floating chloride in the tissues is about 12 grammes in 1.5 to 2 kilos. of water. The power of eliminating chlorides varies considerably in different individuals, and some cases of dropsy due to the habitual excessive consumption of salt by otherwise healthy persons have been recorded. These, of course, are immediately cured if the cause is removed.

In many cases of Bright's disease the permeability of the kidneys to salt is greatly impaired, water is in consequence retained, and oedema results. The relation between the hydration of the tissues and salt retention in nephritis was first demonstrated by Widal, in a classical case, of which I now show the chart. The patient was under observation for 62 days. Nine sudden changes were made from a salt-containing to a

salt-free diet, or *vice versa*, retention of chloride being provoked four times, dechlorination five times. Four times there was hydration of the body, and five times dehydration. In this case the kidneys had considerable power of eliminating chlorides—much more than in the first of my own cases, for instance.

This theory of the relation of chlorides to nephritis has been amplified in several directions: in particular, Widal has tried to show that some of the symptoms of uræmia are related to salt retention, others to retention of nitrogen. This question, however, may be left aside here. Before passing to cite cases, I shall only allude to two further matters:—

1. *The Pre-œdematous Period.*—You will notice in the chart shown that œdema only becomes manifest after the patient's weight has already risen considerably. During the preliminary gain hydration is affecting the internal organs before it involves the subcutaneous tissues. In the same way the weight continues to fall after all visible œdema has been removed. Thus the disappearance of visible œdema does not show that the viscera have recovered. We must wait for this until the body weight has reached its minimum.

2. *Variations in Renal Permeability to Salt.*—Widal's patient had considerable power of eliminating salt. In some cases, however, this power may be almost *nil*. After a patient has been dechlorinated, measured quantities of salt should be added to the diet, his weight being ascertained daily the while, in order to ascertain the tolerance of his kidneys. In some cases it will be found that whereas before dechlorination he could eliminate very little, after dechlorination the kidneys have regained some of their permeability. This is apparently due to the removal of the œdema of the kidneys, which occurs as a part of the general hydration of the viscera, and in itself directly impairs the renal permeability. On the whole, dechlorination tends to diminish the percentage of albumin in the urine, probably simply by causing diuresis.

Sodium chloride is apparently the only salt which needs to be considered in relation to œdema, and Widal seems to regard chloride retention as the only cause of the dropsy of Bright's disease. Most authorities, however, do not accept this simple theory as explaining all forms of œdema. However this may be, there is no doubt that in its practical application the theory of salt retention is a valuable guide to treatment.

In illustration of the effect of dechlorination, I give an account of a case recently under treatment. I have to thank Dr. Gordon, my House Physician, for the careful estimation of the chlorides in this and in other cases.

L. C., æt. 7½, has suffered from chronic Bright's disease for four years, during which time he has several times been an inmate of the Sick Children's Hospital. He comes in from time to time with more or less œdema, scarcity of urine, and a large quantity of albumin. With the exception of the first attack and the present one, he has usually improved within a few days, under ordinary treatment, the œdema disappearing, the urine becoming abundant, and the albumin falling to a mere trace. He was admitted to hospital this year on April 27th, with the usual symptoms. Apart from moderate general œdema and albuminuria none of the other systems of the body were affected. He was treated in the ordinary way with purgatives, hot packs, and saline diuretics and a milk diet, and by the 7th of May was free from œdema, having lost 3½lbs. in weight. His diet was increased so as to include chicken soup, bread, farinaceous food, and a little fish. About the 15th

of May his weight began to go up, and the quantity of his urine diminished, and on May 20th he became visibly œdematous. Notwithstanding a renewal of the previous treatment the œdema became much worse, his urine was loaded with albumin, and he was passing only .7 gramme of chloride daily. On June 1st a salt-free diet was begun, including one pint of milk daily. His weight was then 51½lbs. (see chart). By June 6th his œdema had disappeared, and two days later his weight had fallen to 42½lbs., a loss of 8½lbs. in eight days. Along with this dehydration, the chloride excretion rose considerably above the quantity ingested—to as much as 7 grammes on one occasion. By June 21st, chloride equilibrium was established, and from that date until the end of the month his weight remained fairly stationary (the gain of 1lb. being probably due to his improved nutrition), his daily excretion of chlorides being between 1 and 2 grammes, corresponding fairly well with the quantity in a salt-free diet.

On July 2nd, with the view of ascertaining the degree of permeability of his kidneys to chlorides, 5 grammes of salt were given, and continued daily for three weeks. The immediate result was to send up his excretion of chloride to 5 and 6 grammes daily, and it was thought that his kidneys were sufficiently permeable to enable him to maintain equilibrium on this quantity. This, however, did not occur. His elimination of chlorides again fell to between 1 and 2 grammes, his weight rose, and by the middle of July œdema had reappeared.

On July 22nd salt was withdrawn from his diet. The change did not produce an effect at once, as on the former occasion. His elimination of chlorides remained low, falling during the first week in August to less than .5 gramme daily; he was retaining at least a gramme per diem, and his weight continued to rise until by August 9th he turned the scale at 55lbs. Then he suddenly began to eliminate large quantities of chlorides, he became dehydrated, and his weight fell to its former level by the 19th. He continued to excrete about 1 to 2 grammes of chloride daily, and was discharged from hospital in the early part of September.

The course of the case during the time he was under observation is shown on the chart.

Unlike some other forms of restricted dietary, a salt-free diet is easy to arrange, and is seldom distasteful to the patient. I have not yet met with anyone who really seemed to feel the want of the accustomed condiment, and most of the adult patients have relished their food, and found the new diet a pleasant variation from the milk and farinaceous food on which they were previously living. The Table gives the percentage of salt in a number of different articles of food.

	Na. Cl. per 1,000
Milk ... ..	1.5—2.5
Eggs ... ..	1.6
Fresh butter ... ..	1.
Bread ... ..	8.—10.
Meat ... ..	.3—1.
Fresh-water fish ... ..	.48
Sea fish ... ..	5.4
Flour ... ..	.17
Rice ... ..	.02
Potatoes ... ..	.57
Peas ... ..	.65
Lentils ... ..	2.3
Fruit ... ..	.30—.2

Milk contains from ¼ to 1 grain per oz., so that a patient on a diet consisting solely of milk (50 to 60 ozs.), may be taken from 37 to 60 grains (2½ to 5 grammes) daily. When a patient suffering from Bright's disease is restricted to milk he is

thus actually being dechlorinated, and probably part of the value of a milk diet depends on its poverty in chlorides. Fresh butter and eggs, though they contain a relatively large amount of salt, are used in comparatively small quantities, and are therefore negligible. Bread, as ordinarily prepared, contains a large quantity of salt, and

have not noticed any unpleasant symptoms from the sudden change. As a rule the œdema at once begins to diminish, and quickly disappears, along with a free diuresis, but in some cases a week or two may elapse before this occurs. In the case described, where the second dechlorination cure was long in producing its effect, we tried reducing

Chart of L.C. Weight, ..... Urine, ..... Chlorides, ..... \* = appearance and disappearance of œdema.

patients subjected to a salt-free diet are debarred from eating it. There is, however, no difficulty in getting bread specially baked without the addition of salt, and this can be supplemented by home-made scones and cakes. Meat, game, poultry, fruit, and cereals contain very little salt, as also do most of the ordinary vegetables. Salt-water fish contains a quantity of salt. When we come to apply these facts to practice we construct a diet according to the following rules:—

1. No salt is to be used in cooking, nor is any to be eaten at meal-times.
2. Ordinary bread, including cakes and scones from the baker, fish, except fresh-water fish, salt butter, cheese, all forms of dried, smoked, salted, or otherwise preserved food, such as tinned meat, bacon, dried fish, and the like, and sauces and pickles must be avoided.
3. Not more than a pint of milk should be taken in the day.
4. Soups made from ordinary meat stock contain large quantities of salt. Without this they are unpalatable. The soup of a patient undergoing a strict diet should be made from vegetables, with a milk stock.
5. Apart from these restrictions the patient may eat what he likes. He may have from a quarter to a half pound of meat or its equivalent as poultry or fresh-water fish per day, and vegetables, cereals, one or two eggs, etc., as his appetite demands. Tea and coffee are not prohibited.

The liberal dietary which is thus possible has two advantages in addition to the favourable effect which it may be expected to exert on the œdema:—(1) It is much less monotonous than the "light diet" which is often the food of the chronic nephritis patient; and (2) the general health and nutrition of a patient who has hitherto lived chiefly on milk often improve greatly.

I have hitherto tried this salt-free diet chiefly in cases of chronic Bright's disease with œdema, and have seen no bad effect from the comparatively large amount of nitrogenous food it contains. I have always begun a strict diet without any preliminary diminution in the salt in the food, and

the proteid in the diet, and soon after there was diuresis and disappearance of the dropsy, whether or not this was merely coincidence I do not know.

In patients treated in this way it is not necessary to estimate the urinary chlorides. The progress of the case can be judged of by regular weighing, or, when this is impracticable, by measuring the urine and noting the disappearance of the œdema. When the weight has become stationary or (when the patient is not being weighed) a fortnight or so after the disappearance of all visible œdema, a little salt may be added to the diet by way of experiment, and the effect on the weight noted. The addition which is most grateful is some ordinary bread. Adult patients, however, become so habituated to this diet, and so conscious of the good it does them, as not to be anxious for any relaxation of it. I have had one case on a strict diet for six months, and she has no desire to change; another patient has been on a partially salt-free diet for a year and a half.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by W. Langdon Brown, M.A., M.D. Cantab., F.R.C.P., Physician to the Metropolitan Hospital; Medical Registrar and Demonstrator of Physiology and Morbid Anatomy, St. Bartholomew's Hospital. Subject: "Sudden Death."

## ORIGINAL PAPERS.

### NOTES ON

### HÆMORRHAGIC DIPHTHERIA.

By J. D. ROLLESTON, M.D., B.Ch. OXON,  
Assistant Medical Officer to the Grove Hospital, Metropolitan  
Asylums Board, London.

*Definition.*—In the present paper the term hæmorrhagic diphtheria is applied to those cases in which in addition to other signs of malignancy hæmorrhages appear in the skin at an early stage of the disease, with or without hæmorrhages from the mucous membranes.

The insertion of the words "at an early stage"

has been made so as to exclude cases of purpura occurring in convalescence from diphtheria such as have been described by Buckley, (a) Goodall, (b) and Barlow. (c) The qualification "in addition to other signs of malignancy" has been used because petechiæ may sometimes develop at the injection sites in cases which are not remarkably severe. These lesions which are usually scanty and minute have no evil significance. Cases in which epistaxis alone occurred, though accompanied by other features of malignancy, have not been dignified with the title of hæmorrhagic diphtheria, nor has the term been applied to malignant cases in which hæmorrhage occurred from beneath the faucial membrane alone.

It is sometimes difficult to determine whether a hæmorrhage is spontaneous, or is due to some slight mechanical cause. It is perhaps best to follow Sevestre, (d) who maintains that the lesion is always disproportionate to the local agent. Thus a bruise may appear over the knee after a light percussion of the extensor tendon, or over a rib after auscultation of the chest.

**Frequency.**—The present paper is based on 1,550 cases of diphtheria which have been under my care at the Grove Hospital in the course of the last six years. Of these, 78 or 5.03 per cent. were hæmorrhagic.

**Classification.**—The cases have been divided into two groups. A. Those in which the hæmorrhages involved both the skin and the mucous membranes (53 cases). B. Those in which the skin only was affected (25 cases).

**Age and Sex.**—23, or 4.1 per cent. occurred in the first quinquennium; 50, or 7.02 per cent. in the second; and 5, or 3.4 per cent. in the third. The oldest patient affected was aged 12 years, though 167 of the 1,550 were above that age. 31 or 4.2 per cent. were males; 47 or 5.7 per cent. were females.

**Seasonal incidence.**—The following figures show that hæmorrhagic cases are almost equally frequent at all periods of the year. Thus 20 or 4.4 per cent. occurred in the first quarter, 14 or 6.03 per cent. in the second, 13 or 4.1 per cent. in the third, and 31 or 5.6 per cent. in the fourth.

Table I. shows that with two exceptions the annual percentage of hæmorrhagic cases has remained practically the same since 1902. The year 1903, for which the Grove Hospital diphtheria case mortality was only 6.0 per cent., was exceptional for its small number of malignant cases. The patients of 1908 cannot fairly be compared with those of the other years, since they represent an unusually large proportion of young children.

TABLE I.

Year.	Total number of cases.	Hæmorrhagic	
		cases.	Percentage.
1902	168	10	5.9
1903	318	9	2.8
1904	200	11	5.5
1905	187	10	5.3
1906	306	16	5.12
1907	295	15	5.08
1908	76	7	9.2
	1550	78	

**Previous health.**—Hæmorrhagic diphtheria in the present series did not show a special tendency to attack weakly children, or those debilitated by a recent illness, as some writers have noted. In none of the cases was any other disease, such as scarlet fever or measles co-existent with diphtheria, 13 had had no previous illness whatever. The others had had one or more of the acute exanthemata, or a previous history of sore throat or bronchitis.

**Character of diphtherial attack.**—In all the cases the faucial membrane was extensive, and one or more of the characteristic features of malignancy were present,

such as faucial and palatal œdema, foetor, disproportionate adenopathy, pitting of the skin over the glandular swelling, and absence of, or a delay in, reaction to antitoxin. Sixty-eight cases, or 87.3 per cent., showed signs of nasal involvement either by membrane visible within the nasal fossæ or by profuse and thick rhinorrhœa. Only 4 had laryngeal symptoms. Two of them required tracheotomy. All 4 died. Enlargement of the liver appreciable during life was found in 32 cases out of 57 hæmorrhagic cases, in whom it was investigated, *i.e.*, in 51.6 per cent. as compared with a percentage of 7.4 among 1,170 diphtheria patients in whom a routine examination of the liver was made. A punctate rash on the knees described by Marfan (a) as characteristic of severe diphtheria, occurred in 11 out of 48 hæmorrhagic cases in which this sign was investigated. Albuminuria was present in every case in which a specimen of urine could be obtained. Complete suppression of urine for 24 hours or more before death occurred in 24 cases, and pronounced oliguria in another 8. With the exception of 39 cases who died of toxæmia during the acute stage, every hæmorrhagic patient suffered from paralysis. It is of neurological interest, as indicating the perturbation of the pyramidal system met with in severe diphtheria, that Babinski's sign was present in 17 out of 38 hæmorrhagic cases, *i.e.*, in 44.7 per cent., as compared with a percentage of 19.1 in a series of 636 cases of diphtheria in which this sign was investigated.

**Day of disease on admission to hospital.**—Table II. shows the day of disease on admission to hospital, which in all but 3 cases was the same as that on which antitoxin was first injected.

TABLE II.

		Percentage frequency among all cases admitted.	
		Cases.	
1st day	.. ..	0	0
2nd	.. ..	3	0.9
3rd	.. ..	14	3.4
4th	.. ..	22	6.8
5th	.. ..	20	9.6
6th	.. ..	10	9.6
7th	.. and later	9	7.5
		78	

Thus no hæmorrhagic cases occurred among those injected on the first day, the percentage among second day cases was small, and the frequency progressively increased with delay in administration of antitoxin. The diminished frequency of hæmorrhagic cases admitted after the sixth day is probably to be explained by the fact that only a small number of untreated hæmorrhagic cases survived after that date. Occurrence of hæmorrhages in those treated comparatively early is to be attributed to a precocious malignancy of the disease and finds a striking parallel in certain rare cases of syphilis in which early adoption of specific treatment does not prevent the disease running a severe and rapidly fatal course (*vide* MEDICAL PRESS AND CIRCULAR. 1., 1907, p. 307, in which I have reported a case of this kind). Of the three cases who had been injected before admission, one had received 2,000 units at home on the third day, was admitted on the fourth, and died on the ninth day of disease. The second had received 2,000 units on each of the sixth and seventh days, was admitted on the seventh, and died on the eleventh day. The third had received 1,700 units at home on the fourth day, was admitted the same day and died on the twelfth day.

**Relation to antitoxin.**—Table III. shows the total amount of antitoxin given in each case. As a rule injection was not made more than once daily, the maximum dose at one time rarely exceeding 24,000 units. The subcutaneous method only was adopted.

Comparative observations of intravenous injection

hæmorrhagic diphtheria state that with the exception of two cases which lived till the 9th and 11th days after the appearance of hæmorrhages, all died within 48 hours, 30 dying within 24 hours. Antitoxin had been given in only 12 cases, 6 of which were moribund on admission. Similar testimony as to the rapidity of death in pre-antitoxin times is given by MacCombie. My own figures show that life in many cases may be prolonged, and in a few saved by the employment of large doses of antitoxin.

Short histories of the cases which recovered will now be given.

CASE 1.—Girl, æt. 5, admitted October 19th, 1902, on 4th day of disease. State on admission: Fauces very œdematous. Membrane covers enlarged tonsils, pillars and uvula, and extends on to soft palate. Much adenopathy. Profuse watery nasal discharge. Knee-jerks absent. 18,000 units.

5th day. Membrane as yesterday. Marked fœtor. Nasal discharge thicker, more profuse and sanious. Adenopathy increased. Bruise over right anterior superior iliac spine. 15,000 units. Adrenalin chloride solution m. v., 4 hourly.

6th day. Throat slightly cleaner. Two fresh bruises over lumbar vertebrae.

10th day. Throat clean.

11th day. General urticaria for one day only.

16th day. Heart shows triple rhythm. Irregularity of force and rhythm lasted till 45th day.

33rd day. Nasal voice.

41st day. Ciliary palsy lasting till 58th day.

43rd day. Late tonsillitis.

47th day. Squint.

54th day. Allowed to sit up.

She walked badly for some days after first getting up in clothes. On her discharge from hospital on the 79th day her knee-jerks were still absent.

CASE 2.—Boy, æt. 4, admitted December 29th, 1902, on 3rd day of disease. State on admission: Fauces and palate œdematous. Tonsils meeting and covered by membrane which invades soft palate. Profuse watery nasal discharge. Stertor and fœtor. Bruises on right shoulder and right leg. 18,000 units.

4th day. Membrane of same distribution. Fauces less œdematous. Bleeding from gums. Two bruises over lumbar vertebrae. 15,000 units. Adrenalin m. v., 4 hourly.

7th day. Albuminuria lasting till 28th day.

10th day. Throat clean.

13th and 14th days. General urticaria.

15th day. Cardiac dilatation lasting till 58th day.

27th day. Palatal and ciliary palsies.

5th week. Pharyngeal and diaphragmatic palsies.

6th week. Paralysis of vesical sphincter.

7th week. Labial palsy and weakness of neck muscles.

8th week. Up in clothes but paraplegic for more than a fortnight.

Discharged after 81 days' stay in hospital.

CASE 3.—Boy, æt. 5, admitted January 3rd, 1903, on 3rd day of disease. State on admission: Dirty membrane covers swollen tonsils, pillars, and part of soft palate. Considerable adenopathy. Profuse and thick nasal discharge. 18,000 units.

4th day. Uvula covered by membrane. Blood-stained nasal discharge. 18,000 units. Adrenalin chloride solution m. v., 4 hourly.

5th day. Numerous petechiæ at second injection site.

7th day. Epistaxis. Albuminuria lasting till 26th day.

9th day. Throat clean.

10th–13th days. Urticaria on trunk and limbs.

20th–43rd days. Cardiac dilatation.

21st day. Palatal palsy.

25th day. Ciliary palsy.

52nd day. Scarlet fever, without complications.

Discharged after 96 days in hospital.

CASE 4.—Boy, æt. 10½, admitted January 28th, 1903, on 6th day of disease. State on admission: Fauces and palate œdematous. Membrane covers both tonsils and pillars and part of soft palate. Pro-

consular neck. Marked fœtor and stertor. Petechiæ on neck and left upper arm. No knee-jerks. Albuminuria lasting till 35th day. 21,000 units. Adrenalin chloride m. v., 4 hourly.

7th day. Fauces as yesterday. Considerable œdema of cellular tissue spreading from neck down to the level of the nipples.

8th day. Bloodstained nasal discharge.

9th day. Numerous petechiæ scattered all over the abdomen. Large hæmatoma at second injection site.

9th–11th and 14th–16th days. General urticaria.

12th day. Cardiac dilatation and irregularity which persisted during stay in hospital.

13th and 17th days. Nausea and vomiting.

30th–57th days. Ciliary palsy.

39th–55th days. Palatal palsy.

60th day. Allowed to sit up.

Walking was unsteady for the first fortnight that he was up. On his discharge after 77 days in hospital the knee-jerks were still absent.

CASE 5.—Boy, æt. 3, admitted February 22nd, 1903, on 6th day of disease. State on admission: Fauces œdematous. Membrane on tonsils and pillars. Profuse nasal discharge. Albuminuria which persisted till 21st day. 18,000 units.

7th day. Profuse epistaxis. Bruises at injection site. Numerous petechiæ scattered all over abdomen and on legs, 27,000 units. Adrenalin chloride solution m. x., 4 hourly.

9th day. Bruises on right forearm. 12th–16th days. General urticaria.

12th–25th days. Vomiting associated with cardiac dilatation and irregularity.

Palatal and ciliary palsies developed in the 4th week and pharyngeal, diaphragmatic, and labial palsies in the 5th week. He was allowed to sit up on the 65th day, but it was another month before he could walk at all well.

He was discharged after 96 days in hospital.

CASE 6.—Boy, æt. 5½, admitted January 20th, 1904, on 5th day of disease. State on admission: Dirty membrane covers tonsils and pillars, part of posterior pharyngeal wall and soft palate. Sanious nasal discharge. Well-marked bilateral adenopathy. Petechiæ in right groin. 21,000 units. Adrenalin chloride solution m. v., 4 hourly.

6th day. Membrane of same distribution. Nasal discharge no longer blood-stained. 21,000 units.

7th day. Albuminuria which persisted till 35th day. 21,000 units.

8th day. Throat clean. Liver edge 2 fingers' breadth below costal margin.

14th–20th days. General urticaria.

14th–18th days. Cardiac irregularity.

20th day. Ciliary palsy lasting till 53rd day.

24th day. Palatal palsy, also gone by 53rd day.

49th day. Sat up. For 11 days after getting up he had some difficulty in walking.

Discharged after 79 days in hospital.

CASE 7.—Boy, æt. 2½, admitted February 18th, 1904, on 5th day of disease. State on admission. Old thin membrane on both tonsils, pillars, uvula and epiglottis. Watery nasal discharge. Albuminuria lasting till 50th day. 18,000 units. Adrenalin chloride m. v., 4 hourly.

6th day. Membrane of same distribution. Bruises on legs and on left posterior superior iliac spine. 21,000 units. Adrenalin chloride increased to 2 hourly doses.

7th day. Epistaxis.

8th day. Throat clean.

17th–18th days. General urticaria.

32nd day. Palatal and labial palsies.

35th day. Pharyngeal palsy. Cutaneous analgesia. Knee-jerks and abdominal reflexes lost.

38th day. Squint and ptosis.

48th–56th days. Cardiac dilatation.

When propped up on the 56th day well-marked palsy of the neck muscles was present. Loss of power in the lower limbs persisted for more than a month after getting up. Discharged after 99 days in hospital.

CASE 8.—Boy, æt. 1 year 10 months, admitted

July 4th, 1904, on 6th day of disease. State on admission: Membrane on both tonsils and anterior pillars. Profuse watery nasal discharge. Moderate adenopathy. 18,000 units. Adrenalin chloride m. v., 4 hourly.

7th day. Membrane of same distribution. Marked fœtor. Adenopathy increased. Epistaxis. 21,000 units. Adrenalin increased to 2 hourly doses.

8th day. Petechiæ on thighs. Bruise over lumbar vertebrae.

9th day. Bruise just internal to inferior angle of right scapula.

10th and 11th days. Epistaxis.

11th day. Slight enlargement of liver.

13th day. Throat clean.

14th day only. A few wheals of urticaria.

15th day. Albuminuria.

20th day. Palatal palsy.

24th-6th days. Cardiac dilatation and irregularity.

39th day. Squint.

56th day. Allowed to sit up. Paraplegia for a fortnight after first sitting up. No knee- nor ankle-jerks on his discharge after 81 days' stay in hospital.

CASE 9.—Girl, æt. 7, admitted December 14th, 1904, on 4th day of disease. State on admission: Fauces œdematous. Membrane covers tonsils, pillars and uvula. Some deposit on epiglottis. Proconsular neck. Bruise over left internal malleolus. 24,000 units. Adrenalin m. v., 2 hourly.

5th day. Membrane of same distribution. Fœtor marked. Bruise on right knee. 24,000 units.

6th day. Membrane still of same distribution. Albuminuria lasting till 33rd day. 24,000 units.

9th day. Punctate rash on knees.

10th-14th days. General urticaria.

11th day. Throat clean.

17th day. Palatal palsy.

22nd-42nd days. Cardiac dilatation and irregularity.

26th day. Ciliary palsy.

39th day. Labial palsy.

56th day. In clothes. No loss of power in limbs, but knee- and ankle-jerks absent. Discharged after 62 days' stay in hospital.

CASE 10.—Boy, æt. 4, admitted December 23rd, 1904, on 4th day of disease. State on admission: Fauces and palate œdematous. Membrane covers both tonsils, pillars, and tip of uvula. Profuse nasal discharge. Membrane visible in nasal fossæ. Moderate adenopathy. Stertor and fœtor. Petechiæ round neck. 24,000 units. Adrenalin chloride m. v., 2 hourly.

5th day. Fauces still œdematous. Fœtor and stertor increased. Thick cloud of albumin in urine lasting till 40th day. 24,000 units.

6th day. Several fresh petechiæ on neck. A few on scapulae. Bruise at second injection site.

7th day. Numerous fresh petechiæ on neck, back, buttocks and legs. Liver 2 fingers' breadth below costal margin. Throat clean.

11th-15th days. Urticaria.

14th day. Palatal palsy.

26th day. Cardiac arrhythmia.

35th day. Ciliary palsy.

42nd day. Labial palsy.

49th-53rd days. Pharyngeal palsy.

54th day. Allowed to sit up, but it was a fortnight before he could walk by himself. The knee- and ankle-jerks were still absent on his discharge from hospital on the 72nd day.

CASE 11.—Boy, æt. 7, admitted March 5th, 1905 on 4th day of disease. State on admission: Fauces extremely œdematous. Thick membrane covers both tonsils and pillars, and is continued as a thin film almost on to hard palate. Adenopathy well-marked. Thick nasal discharge. Membrane visible in nostrils. Much fœtor. 24,000 units. Adrenalin chloride m. x., 2 hourly.

5th day. Delirious in night. Bruise on left calf and back of left hand. 24,000 units. Albuminuria lasting till 31st day.

8th day. Liver 1 finger's breadth below ribs. Throat clean.

11th-12th days. Urticaria.

11th day. Palatal palsy lasting till 60th day.

15th-27th days. Cardiac dilatation and arrhythmia.

28th day. Ciliary palsy.

50th day. Squint, ptosis and diplopia.

Some motor paresis for a fortnight after he was first up in clothes.

Discharged after 78 days' stay in hospital.

CASE 12.—Girl, æt. 7, admitted at 12.15 a.m. on March 14th, 1906, on 5th day of disease. State on admission: Fauces œdematous. Thick membrane covers tonsils, anterior pillars, uvula, and part of soft palate. Watery nasal discharge. Stertor and fœtor. Proconsular neck. Albuminuria persisting till 41st day. Babinski's sign in both feet lasting till 33rd day. 24,000 units. Adrenalin chloride m. x., 4 hourly. 1.20 p.m., 24,000 units.

6th day. Hæmorrhage from beneath membrane on palate.

7th day. Sanious nasal discharge.

8th day. Numerous petechiæ on back and sides of thorax. A few round neck and in left groin. Punctate eruption on knees. Bruise on right iliac crest.

9th day. Hæmorrhage from fauces. Voice nasal.

11th day. Throat free of membrane. Extensive superficial necrosis of epithelium of tonsils, uvula, pillars, and soft palate.

12th day only. A few small wheals on abdomen.

25th day. Ciliary palsy.

33rd-49th days. Cardiac dilatation and irregularity.

40th-60th days. Labial palsy.

Transferred to convalescent hospital on 70th day of disease. No loss of power in limbs, but knee- and ankle-jerks absent.

CASE 13.—Boy, æt. 5, admitted April 1st, 1908, at 12.15 a.m. on 5th day of disease. State on admission: Fauces and palate œdematous. Membrane covers tonsils, pillars, uvula, and soft palate. Profuse nasal discharge. Proconsular neck. 28,000 units. Adrenalin m. x., 4 hourly.

11.15 a.m. Much epistaxis. 24,000 units. Adrenalin increased to m. x., 2 hourly.

6th day. Bruise over tubercle of left tibia.

7th day. Bruises over right posterior iliac spine. Sanious nasal discharge. Albuminuria persisting till 44th day.

9th day. Throat clean.

12th day. Palatal palsy lasting till 52nd day. Heart sounds indistinct. Liver edge 1 finger's breadth below costal margin.

12th-13th days. A few small wheals on abdomen.

15th day. Urticaria on face and thighs.

21st day. Ciliary palsy lasting till 45th day.

25th-64th days. Cardiac irregularity and dilatation.

32nd day. Labial palsy.

76th day. In clothes. For a few days he was unable to walk without support. The knee- and ankle-jerks which were sluggish on admission were lost by the 32nd day and were still absent on his discharge on the 101st day.

It will be seen that all these cases showed the characteristic features of malignant diphtheria. In addition to severe angina, all but one had some degree of nasal involvement. Albuminuria was present in all. In 9 it was abundant, and lasted for more than three weeks.

All developed extensive paralysis. Palatal palsy occurred in all, in 4 it was precocious, i.e., appeared before the beginning of the third week. All but two who were too young to test, showed ciliary palsy. All manifested some degree of cardiac dilatation and irregularity. In two there was cardiac vomiting. Ten showed considerable weakness of the lower extremities which persisted for a fortnight or more after first getting up. In two of the remainder though there was no actual loss of power, the knee- and ankle-jerks were abolished (paraplegie fruste of Aubertin and Babonneix. (a) Labial palsy was noted in 6, squint

in 4, paralysis of the pharynx in 4, and of the diaphragm in 2.

The length of stay in hospital was considerably longer than the average, though only one patient (Case 3), developed a secondary disease—scarlet fever. The shortest stay was 62 days, the longest 97, and the average period, 80 days.

The treatment in each case consisted in large doses of antitoxin, the justification for which will be seen in Table III., and in the internal administration of adrenalin. This drug was given not so much for the sake of controlling the hæmorrhages, which in no case were sufficient to endanger life, but to compensate for the suprarenal insufficiency, clinical and anatomical evidence of which exists in every severe case of diphtheria.

#### SUMMARY.

1. Cutaneous hæmorrhages occurring during the early stages of the disease with or without hæmorrhages from the mucous membranes and associated with other features of malignancy, occur in about 5 per cent., of all cases of diphtheria.

2. The severity of the diphtherial attack is usually due to neglect of treatment at an early stage, but is sometimes due to precocious malignancy (*cf.* syphilis).

3. Hæmorrhagic diphtheria is confined to children. It is not affected by the season, sex, or previous health.

4. Reaction to antitoxin is delayed, and the usual sequelæ of serum treatment are much less frequent in hæmorrhagic than in milder forms of diphtheria.

5. The mortality of hæmorrhagic diphtheria is over 80 per cent.

6. All the cases which recover suffer from extensive paralysis.

7. Treatment should consist in large doses of antitoxin associated with frequent administration of adrenalin.

## QUACKS, FALSE REMEDIES, AND THE PUBLIC HEALTH.

By DAVID WALSH, M.D.Ed.,  
Senior Physician, Western Skin Hospital; Physician, Kensington and Fulham General Hospitals.

### PART III. KIDNEY CURES.

THE heartlessness of the nostrum vendor is nowhere more apparent than when he promises to cure chronic kidney disease. Needless to say, chronic Bright's disease is accompanied with changes in the delicate structure of the kidney that are past cure. It is here that, under skilled medical supervision, the life of a patient thus affected may be prolonged for many years in comfort. In the case of the secret remedy, however, there is no skilled supervision; the whole transaction affords an apt illustration of the blind leading the blind. The medically unskilled invalid diagnoses his own kidney disease, and buys the secret remedies of the medically unskilled nostrum vendor. As often as not he gets jalap or some other remedy which, although it will not materially shorten his days, yet cannot possibly better his kidney disease, assuming the latter to exist. The only ray of comfort to be gleaned comes from the reflection that many of the persons who buy these remedies are not really suffering from any kidney disease.

Years ago it came to the author's knowledge that a prominent member of Parliament, a titled man, since dead, was a shareholder in one of the most notorious of the kidney cure companies then and still in existence.

A much advertised internal remedy for baldness has been found to contain hæmoglobin, "the dead colouring matter of the blood of warm-blooded animals." There is not any scientific evidence to show that either hæmoglobin or any other drug can exert a specific action in promoting the growth of the hair when taken internally.

EXISTING METHODS OF CONTROL, DIRECT AND INDIRECT, OVER QUACKS AND QUACKERY.

It may be said at once that there is no effectual control over the evil of irregular medical practice.

The Charter of Henry VIII. empowering and directing the Royal College of Physicians of London to deal summarily with false practitioners and false "poticaries" in London and seven miles round has not been properly carried out, although again and again ratified in successive Acts up to the Medical Act of 1858, which created the General Medical Council. Their penal powers, however, were exercised intermittently for centuries and in the year 1857 we find the College asserting its right in "Churchill's Medical Directory" to commit offenders to Newgate. Section 40 of the Medical Act, 1858, made it a penal offence for any unqualified person to assume a medical title or any title implying him to be registered under the Act. In practice, owing to the interpretation of this section by judges and police magistrates, the Act is easily evaded by any charlatan. The only other method of prosecuting false practitioners is under the Apothecaries' Act, whereby that body is empowered to prosecute unqualified persons practising medicine, but only when they sell their medicines as well as advice. This provision, again, is easily evaded by the quack, who need only sell his advice and throw his physic into the bargain. Feeble as this means of control of irregular medical practice may be, it is the only one that has been available for generations past, in the absence of or the extremely infrequent action on the part of the police. That state of matters is hardly creditable to a legislature that recognised the evil and created ample and drastic powers to deal with it some four hundred years ago. The foregoing and some other existing methods of dealing with false practice and false remedies—for the two things are, in the author's opinion, inseparable—will next be considered somewhat in detail.

#### POLICE ADMINISTRATION.

The powers of the police over fraudulent quacks and secret medicine vendors are great. They have only to follow up advertisements of a suspicious nature to discover the real nature of the methods pursued in any given case. Naturally, the police are loth to prosecute under the penal section of the Medical Act, inasmuch as the difficulty of obtaining convictions under that Act is notorious. It is open to the police authorities, however, to prosecute for the offence of obtaining money under false pretences. From our short analysis of the nature of secret remedies of the baser type, it will be readily seen that the exposure of their worthlessness would be in most cases an easy matter. No doubt such prosecutions, from the need of expert evidence and of good counsel, would be costly, but that is true of all criminal prosecutions undertaken in the interests of society. Something may be done locally by bringing pressure to bear upon Watch Committees and County Councils, or in London, where the police outside the City proper are not under popular control, upon the Home Office. It is to the latter central administration that the public should naturally look for protection against fraud, were there only a properly organised system of public prosecution in existence. It is a well-recognised fact that notorious frauds may be carried on for many years, after repeated exposures in the newspapers, without any attempt at interference on the part of the authorities. The unhappy man who has once been convicted of the most trivial offence is an object of police suspicion, and sometimes of police supervision, for the rest of his days, whereas an unconvicted rogue may practice notorious frauds and live a life of undisturbed luxury. Surely the prevention of fraud is a higher police function than the surveillance, say, of an unhappy wretch who has presumably purged his offence by undergoing a term of imprisonment.

Of late, however, the police have instituted prosecutions in the case of several notorious quacks, and happily with invariable success.

Dr. A. G. Bateman has reminded the writer that in this respect the Chief Constable of Brighton deserves the highest praise for his successful crusade against the quack practitioners within his district. For instance, a year ago he secured the conviction of a notorious offender, who for many years had been living in Brighton in great style, and was known for the well-appointed equipage which he drove on the

Parade daily. This man, by means of specious advertisements of a semi-religious type, and a stock of carbonate of soda and bromide of potassium, and sold as a cure-all under a grandiloquent name, made an income which would have almost fallen under the lines of the super-tax. The Chief Constable, securing ample evidence, proceeded against this well-known townsman, and, after committal to Lewes Assizes, a conviction was obtained, and imprisonment followed for false pretences. Brighton can no longer be a safe and pleasant residence for quack doctors, and if Chief Constables of other cities and towns would only follow the excellent work done by their Sussex colleague, the public would be saved many thousands of pounds a year.

The attention of the Home Office and of the police can hardly fail to have been drawn to the scathing condemnation of Bile Beans already quoted. Four Judges—namely, Lord Low, Lord Kyllachy, Lord Stormouth Darling, and Lord Justice Clerk—who delivered judgment, concurred in the application to the Bile Beans business of such terms as "gigantic and too successful fraud," "deliberate inventions," "lying tale," "a deliberate fraud upon the public," "fraudulent misrepresentation," "business based upon unblushing falsehood." With such evidence one would imagine that the police and the Home Office would not hesitate to take action against newspapers inserting advertisements of a business thus characterised in a British Court of Justice. Yet these advertisements have since been published systematically in the public newspapers. Surely any Home Secretary who found himself unable to deal effectually with an evil spoken of by four Judges of the High Court in terms of scathing condemnation, should at once apply to Parliament to place in his hands the necessary powers.

#### THE PENAL POWERS OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

The Royal College of Physicians of London came into existence under a Charter granted by King Henry VIII. (a) Amongst the various reasons given for incorporating the College was the following (b):—"After the example of other nations, the King has determined to found a College of the learned men who practise physic in London, and within seven miles, in the hope that the ignorant and rash practicers may be restrained or punished." From this it is evident that the keynote to the whole Charter was the desire to suppress irregular medical practice.

Under the Charter the College of Physicians was empowered to examine candidates and to grant a licence to practice medicine. No one was permitted to "exercise the faculty" without the College licence under a penalty of £5 per month, half of which was to go to the Crown and half to the College. Under this Charter the president and elects of the College had summary powers to imprison false practitioners and to visit "poticaries," inspect their drugs, and punish those who had bad drugs, as well as to destroy their wares.

The penal powers given in 1518 have never been repealed. Great as was the power against irregular medical practice and remedies, it was increased under Mary, who confirmed the previous Charter in every particular. (c) In Section 4 it directs that whensoever the President or Commonalty of the Faculty of Physic of London "shall send or commit any such offender, for his or their offence or disobedience, contrary to any article or clause contained in said grant or Act to any ward, gaol, or prison within the same city and precinct, the gaolers, etc., shall receive them until the President discharge them."

This section conferred specifically on the College of Physicians the power to imprison quacks and false drug vendors on their own summary authority, and apparently to detain them as long as they might think fit, or at any rate until the fines were paid. Under it imprisonment and fines were repeatedly inflicted by the President of the College. There can be no

doubt as to the precise meaning of the Act of Mary, for in Section 5 it says:—"And further be it enacted by the authority aforesaid, for the better execution of the search and view of the 'poticary wares, drugs, and composition, according to the tenour of a statute made in the 32nd year of the said King Henry VIII.;" the section then goes on to empower the President to act in failure of wardens of gaols and others.

The power was confirmed in 15 James, Oct. 15th, although this particular charter was not presented to Parliament for approval, and again in 54 George III., cap. 118, which extends disciplinary powers over qualified men throughout England, and all powers to Westminster.

The Charter of Henry VIII. was finally confirmed in the Medical Act of 1858, thus bringing the penal powers in unbroken succession from 1518 to the present day. The new Act gave power to the Royal College of Physicians of London of applying for a new Charter under the title of Royal College of Physicians of England, but the College has not availed itself of the permission. Section 47, on condition of surrendering all Charters except that of Henry VIII., and confirming all rights, powers and privileges of Henry VIII., c. 5, as far as such chapter and Act are inconsistent with the new Charter.

In 1860 a short Act to amend the Medical Act of 1858 was passed (23 and 24 Vict., cap. 66). It dealt with the College of Physicians of London, and repealed letters testimonials (qualifying powers), but expressly (Section III.) confirmed "all existing rights, powers, authorities . . . duties and privileges."

From the foregoing account it would seem that the powers of the Royal College of Physicians with regard to quacks and quackery in London and within a compass of seven miles have been confirmed by all subsequent legislation. The matter is of great importance when we regard the failure of the General Medical Council, created by the Medical Act of 1858, to exercise control over any form of unqualified medical practice.

Assuming, for argument's sake, that the General Medical Council absorbed the ancient (if neglected) duties of the Royal College of Physicians of London to control quackery in and around the metropolis, let us inquire why their penal function in that respect has proved a failure. The Penal Section of the Act runs (§40):—

"Any person who shall wilfully and falsely pretend to be or take or use the name or title of a physician, doctor of medicine, licentiate in medicine or surgery, bachelor of medicine, surgeon, general practitioner, or apothecary, or any name, style, title or addition or description implying that he is recognised by law as a physician or surgeon, licentiate in medicine and surgery, or a practitioner in medicine, or an apothecary, shall on summary conviction for any such offence pay a sum not exceeding £20."

To the non-legal mind the section appears to afford ample safeguard against the quacks, but in practice the proverbial coach and four has been driven repeatedly through Section 40. This fact has been well stated by Dr. A. G. Bateman, the Secretary of the Medical Defence Union, who has had an unrivalled experience in the working of the Medical Acts. He quotes the opinion of a learned counsel that, in order to secure the conviction of an unqualified person, the following points must be considered:—

"It is not enough for the prosecution to prove that the accused is not registered.

"It is not enough to prove further that he calls himself by a registrable title or some title that is rather like a registrable title, or seems to imply medical skill and knowledge.

"It is not enough to prove still further that he has no right to the title at all.

"You must go further still and prove that he has no reasonable grounds at all for thinking that he had the right to use the title, so as to leave no other alternative but the inference of a deliberate attempt to impose upon the public.

(a) September 23rd, 1518, 10 Henry VIII.

(b) See Charter in the Official Book of the Royal College of Physicians of London, 1897.

(c) Mary, Sess. 2, Cap. 9, Royal College of Physicians of London.

(a) "Unqualified Medical Practice," A.G. Bateman, M.B., "National Health," August, 1908, p. 175.

"In other words, you have to prove actual fraud and a personal knowledge of that fraud by the offender." (a)

It is clear that, under such conditions, the Medical Act could have few terrors for the unqualified charlatan—and indeed such has been the case. An interesting illustration of the futility of Section 40 is given by Dr. Bateman. It deals with one Bridgwater, calling himself M.D., U.S.A., although no such medical degree was in existence, who carried on an extensive medical practice in Cardiff. He was proceeded against by the Medical Defence Union before the stipendiary under the 40th Section of the Medical Act, but the summons was dismissed on the ground that there was no "implying" that the respondent was registered. An application was then made to the High Court for a *mandamus* to compel the magistrate to state a case, but this was also refused, and one of the Judges of the Divisional Court remarked that "on the cases stated there is a complete fog. It is impossible to say whether this is a question of law or fact."

Bridgwater, so this interesting narrative proceeds, continued to practise, but came to the larger field of London, where, under the guise of the Progressive Medical Alliance, he carried on frauds of various kinds, until, in 1906, he was convicted at the Old Bailey for forgery, and was sentenced to penal servitude. In the opinion of the police who gave evidence, his criminal career was enabled to be carried on with impunity for many years, in consequence of the "cover" of his so-called medical practice.

Comparing the Medical Act with analogous Acts framed to protect the public against unqualified practice in dentistry and veterinary surgery, we find an amazing difference. A conviction has been obtained against an unqualified dentist for merely putting up a statement that teeth were skilfully extracted, on the ground that the statement implied qualification. A man at Kingston-on-Thames who advertised himself as a "canine specialist," was convicted for implying that he was specially qualified to practice a branch of veterinary surgery. Had a hundredth part of this rigorous interpretation been exercised by police court magistrates upon Section 40 of the Medical Act, the public would long ago have been as well protected against quacks and injurious secret remedies—which are in essence a mere offshoot of unqualified practice—just as effectually as they are with regard to their teeth and to the health of their dogs, cats and horses.

But what have the General Medical Council been doing for the fifty years it has been in existence? Have they ever tried to protect the public from the evils of quackery? Have they ever attempted to secure revision of the Act by the Legislature in order to make good the defects revealed in its application? The answer is, that the General Medical Council have failed in their duty towards the nation no less flagrantly than the Royal College of Physicians of London failed with regard to the metropolis. It is only in 1909 that the Council has, acting upon a sub-committee report, presented to the Government the following resolution:—"That the General Medical Council, being of opinion that the present Medical Acts do not sufficiently enable persons requiring medical aid to distinguish qualified from unqualified practitioners, and that it is contrary to the interests of the public that medical and surgical practice should be carried on with impunity by persons holding no recognised qualifications, request the Government to take steps for the appointment of a Royal Commission to inquire into the evil effects produced by the unrestricted practice of medicine and surgery by unqualified persons."

It is due to the efforts of the Direct Representatives of the medical profession upon the General Medical Council that the matter was brought to the front. On the original motion of Dr. Langley Browne, seconded by Dr. L. S. McManus a Committee was appointed to investigate the laws as to unqualified medical practice existing in the colonies and dependencies and in foreign countries. When the report of the committee was received the General Medical Council decided to ask the Privy Council to inquire into the

subject in the United Kingdom by commission in the terms of the above resolution.

In answer to this request the Government issued a Memorandum in 1909 to Medical Officers of Health asking them to furnish reports of any evils they may have met with in connection with unqualified practice. In view of the nature of the occupation of sanitary officers it seems likely that much more direct information could have been obtained from hospital surgeons, general practitioners, police surgeons and coroners. However, it may be presumed the General Medical Council were not consulted on the point. That august body may be congratulated on having gone so far as to recommend the appointment of a Royal Commission, which, as already stated, is here regarded as including the lesser question of the sale of secret remedies in the greater term, "unqualified practice."

The indifference hitherto shown by the General Medical Council to the failure of the penal section of the Medical Act of 1858 may be traced to its constitution. Of its 34 members, 5 are Crown nominees, and 24 representatives of the various qualifying Universities, colleges and halls, while 5 only are directly elected representatives of the medical profession. As the various qualifying bodies are for the most part governed by irresponsible Councils or by the higher diplomates, to the exclusion of the rank and file of the college, it follows that the nominees of such bodies on the General Medical Council do not represent the main mass of qualified medical men but rather autocratic corporations and selfish interests. In a General Medical Council thus constituted, it is natural that troublesome questions such as the failure of the Medical Act to suppress quacks and quackery should be neglected. A matter of that kind, vital as it is to the welfare of the public and the protection of the medical profession, could bring nothing but disturbance into the serene atmosphere of college halls and council chambers. It is fairly safe to say that if any strong and wholesome representation of the real medical life of the country—in the shape of the general practitioner—had been permitted in the General Medical Council during the past fifty years, the question of the penal prosecution of quacks would long ago have been settled.

Imagine a great body like the General Medical Council faced with the failure of Section 40 of the Medical Act. There is nothing to show—so far as can be ascertained—that they have ever taken any bold and vigorous steps towards obtaining a strengthening amendment to that Act. Supposing for the moment the oft-ratified duty of the London College of Physicians to have been merged by the Act of 1858 in the powers and duties of the Council, have they ever considered how that solemn duty to the public could best be discharged? Or, if the London College be supposed to retain the duties as to the prosecution of quacks imposed by its original Charter, have the General Medical Council done anything to bring home to the physicians a sense of their responsibility and of their neglect? Or has the representative of the Royal College of Physicians, who has sat on the Council for fifty years, ever raised the pertinent point as to whether the duty of quack prosecution still lay with the College, or had been transferred to the General Council, or had lapsed into no man's land?

The foregoing observations are clearly made from one point of view, and it is possible that both the Council and the Royal College of Physicians may have a satisfactory explanation from their side of the question. An obvious answer of the Council would be that it was no part of their duty to prosecute quacks or to strengthen defective Acts. There would doubtless be some force in such an argument, but at the same time it must be borne in mind that they were called into existence by the Act of 1858, which purports to be framed in order to enable the public to distinguish qualified from unqualified practitioners by means of an official *Register* and by other provisions. Surely it is the bounden duty of a Council created for such a purpose to use its great influence with the Privy Council to take steps to amend that particular Act, which is open to the fatal flaw that it permits the use of medical titles and the practice of medicine by unqualified persons.

To the average layman it would seem a clear enough duty of the General Medical Council long ago to have secured final decisions in the High Courts of doubtful reading of the Act that brought them into existence, and to have striven to their utmost to get the penal clauses strengthened by Parliament.

Similarly, the Royal College of Physicians may say that their duties were superseded in the Act of 1858. That hardly coincides with the small special Act of 1860, which expressly confirms all the duties and privileges granted under the Charter of King Henry VIII. These duties were imposed as some kind of return for the monopoly of granting qualifications to practice medicine granted to the College. The privileges are retained to this day, but the duty of prosecuting false practicers and false 'poticaries has been neglected. The duty can hardly be said to have become obsolete, as some laws such as the ancient Act regulating the observance of the Lord's Day have become obsolete. The duties of the Royal College of Physicians have been confirmed in subsequent Acts up to 1858 and 1860. They were exercised at times over quacks for two centuries or more and were publicly affirmed by the College itself, as already stated, in the Medical Directory for the year 1857. If the Legislature, then, be in need of an instrument, they may conceivably turn to the Royal College of Physicians, and ask that body for an account of their stewardship during the last 390 years.

It is worthy of note that, in the opinion of Dr. Norman Moore, a gentleman well versed in the history of the London College, up to the year 1906, there had been no material alteration in the constitution of the College. In a notice of that body he said that it was provided in 1518, when Henry VIII. was full of his youthful zeal for knowledge, and "has continued without any material alteration to the present day." (a)

Parliament, however, in search for a method of revivifying the General Medical College and the qualifying bodies of the United Kingdom, could effect that purpose by a stroke of the pen. The constitution of the Council is for the most part that of the non-representative nominees of the constituent corporation. There is nothing in the Act to show how those representatives were to be chosen. Parliament or the Privy Council has simply to decide that in future the representative of every qualifying body upon the Council shall be elected by their respective graduates or diplomates.

As regards the Royal Colleges of Physicians and Surgeons of England, Scotland, and Ireland, the government is in the hands of the Councils and Fellows, to the exclusion of the lower ranks of diplomates, namely, the licentiates, and in some instances the members. As the Colleges draw the bulk of their revenue from the lower ranks, it follows that the exclusion of the latter from any part in the government of the colleges runs counter to the modern democratic view that those who contribute income should have a voice in its expenditure.

Far as the cry may seem, it is not unlikely that the autocratic and largely irresponsible government of the Colleges has a direct relation to the prevalence of quackery. Had the qualifying corporations been governed by the rank and file of the medical profession, and had the majority of the Council been representative of medical practitioners generally, instead of the corporations, they would long ago have contrived to deal with the blatant evils arising to the public from the practice of quackery. Surely the legislative wisdom of the nation can cope with an evil which was emphatically denounced and legislated against 400 years ago.

With the question of the government of the Colleges that of a single portal qualification is closely connected. The public, when once fully informed of the grotesque nature of the present position with regard to medical qualification, will be likely to cut the Gordian knot in a simple and direct fashion. For instance, the English Colleges are at present amalgamated to give a conjoint qualification, M.R.C.S. England, L.R.C.P. London. Why should they not be united into a single body, giving a single qualifica-

(b) *Brit. Med. Journ.*, June 1st, 1906.

tion? Why should not the Scotch Colleges—three in number—be united in a similar manner? Why, indeed, should not the English, Scotch, and Irish Colleges and Halls—that is to say, nine qualifying bodies—be amalgamated with a single qualification? There need be no disconcerting disturbance of teaching methods and ancient traditions. The interests of the public and of the medical profession would be advanced in various ways by the institution of a single professional qualification, a plan that answers well enough in the sister profession of the law.

(To be continued.)

## THE TREATMENT OF CASES OF MUSHROOM POISONING

By PROF. J. MAHEU, M.D.,  
Of the Faculty of Medicine of Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

POISONING by mushrooms is, as a rule, an accident that calls for immediate treatment, and as this varies to some extent according to the nature of the intoxication, our first duty must be to ascertain what kind of mushroom has been eaten, and this, fortunately, is not usually a matter of any difficulty.

In every instance the first thing to be done is to get rid of the toxic material by the aid of emetics and purgatives. As an emetic nothing is better than ipecacuanha; tartar emetic should on no account be employed, more particularly in cases of poisoning by any of the bulbous agarics, which give rise to stupor, algidity, and extreme prostration. In order to obtain a quicker action, a little emetine may be added to the powdered ipecacuanha:—

Pulv. ipecac., 25 gr.

Emetine,  $\frac{1}{2}$  gr.

To be stirred up with a pint of tepid water, a tumblerful to be swallowed at short intervals.

Should we fail in our attempts to induce emesis, and in cases at an advanced stage, we must avail ourselves of the stomach tube, an instrument without which no medical equipment can be considered complete, especially in the country. We must wash out the stomach, and when we have done that we may introduce stimulants—coffee, spirits of ammonia, ether, brandy, etc.—in order to combat the symptoms of excitement or depression, whichever may be present.

In presence of contraction of the jaw muscles, and in dealing with fractious children, we may prefer to employ a hypodermic injection of apomorphine:—

Aquæ dest., 16 min.

Apomorphine hydrochlor.,  $\frac{1}{4}$  gr.

For children a tenth of a grain or less will be sufficient.

Fortunately, the earliest effect of poisoning by mushrooms, especially those possessed of acrid and irritating properties, is to induce salutary vomiting and profuse diarrhoea. Our duty in this case is to assist Nature, and, independently of pharmaceutical agents, to promote free vomiting by administering tepid strongly-salt water, olive oil, or sulphate of copper, which can usually be obtained everywhere, and can be employed in small doses:—

Cupri sulphatis, 2 gr.

Sacchari pulv., 1 dr.

Stir up in 1 or 2 spoonfuls of water, and repeat twice or three times.

Having emptied the stomach, give milk, mucilages, linseed tea, or white of egg beaten up with water, or we may follow Boudier's advice and give a weak solution of iodide of potassium, which is the antidote for the agarics:—

Potassii iodidi, 15 gr.

Tinct. iodi, 10 gtt.

Aquæ dest., 4 fl. oz.

In tablespoonful doses.

Although purgatives cannot act as effectually as emetics, it is well to give them, with a preference for emeto-cathartics in slight cases:—

Emetine,  $\frac{1}{2}$  gr.

Sodii vel magnesii sulph., 5 dr.

In two tumblers of water. To be given after the

emetics to clear out the mushroom residues that may have passed into the intestine.

Of course, any purgative may be made use of under such circumstances—sulphate of soda, castor oil, sulphate of magnesia, etc. Avoid drastic purgatives such as senna and jalap, which would only aggravate the gastro-intestinal irritation.

No reliance can be placed on enemata for the purpose of emptying the bowel, but they may be useful in hastening the effect of purgative medicines. Later they may be useful in allaying pain and inflammation, in the form of opiated enemata, while if there be coma or stupor we may inject hot black coffee, wine or brandy, duly diluted.

Then the abdomen may be rubbed with sedative embrocations:—

Lin. camph., 2 fl. oz.  
Tinct. belladonnæ, 5 dr.  
Liq. opii sed., 1 dr.  
Chloroformi, 2 dr.

In cases of poisoning by agarics containing muscarine (false orange, the panther agaric, etc.), the symptoms are more sudden and violent, but the lines of treatment are the same, except that we must make more use of remedies having for object to subdue cerebral excitement and delirium. Ether appears to be as good as anything, and it is usually at hand, and with it may be associated laudanum, bromide of potassium, and chloral by the mouth or in enemata.

The various symptoms presented by the patient may be combated as follows:—

*Somnolence, Coma.*—Mustard plasters, counter-irritants, dry friction, or rubbing with alcohol or brandy; baths.

*Delirium and Convulsions.*—Tablespoonful doses of the following mixture, repeated half-hourly:—

Tinct. moschi, 15 min.  
Potassii, 50 gr.  
Syrup etheris, 1 āā 10 dr.  
Aque menth. pip., 1

In presence of violent convulsions give:—

Chloral hydratis, 1 dr.  
Syrup aurantii flor, 4 dr.  
Aque, 3 fl. oz.

A fourth part of this mixture to be given at intervals of a quarter of an hour. Chloral may also be given in enemata.

*Vomiting.*—Ice and iced drinks, effervescing mixture.

*Abdominal Pain.*—Fifteen or 20 drops of liquid extract of opium in sweetened water, to be given in three doses at 20 minutes interval; or we may give 20 or 30 drops in an enema or a hypodermic injection of a fifth of a grain of hydrochloride of morphine. Avoid alcoholic vehicles which may dissolve the alkaloids or toxins, and do not allow the morphia injections to be given by others. Nevertheless, after the emetics and purgatives have done their work, we may prescribe the following mixture:—

Spt. etheris co., 30 min.  
Tinct. cannellæ, 2½ dr.  
Ammoniac acetatis, 1½ dr.  
Spt. vini gallici, 1½ fl. oz.  
Syrup etheris, 1 fl. oz.  
Aque menth. pip., 2 fl. oz.

To be given in tablespoonful doses every half-hour.

It is, however, especially in presence of phallogid symptoms—that is to say, poisoning by members of the group of bulbous agarics (*Ammanita phalloides*, *A. citrina*, *A. virosa*, etc.)—to which nine-tenths of the fatal cases are due, that prompt and vigorous treatment is indispensable. In contrast with the effects of the groups previously mentioned, the symptoms of poisoning are manifested but slowly—half a day or even a day after the ingestion of the mushroom. At that stage we are confronted by grave symptoms—stupor, cardiac depression, adynamia, etc. It behoves us to employ forthwith mustard poultices, powerful counter-irritants, active friction of the skin, and hot baths whenever possible. Subcutaneous injections of ether, or even strychnine, in fiftieth-of-a grain doses, may prove useful; coffee, tea, and acetate of ammonia will also be of service.

Hypodermic injections of caffeine at the rate of 8 grains in the day is good treatment, especially in

presence of cardiac depression. It may also be given in mixture form, combined with ether, and this may be administered by anybody, whereas the hypodermic injections of strychnine should be reserved for the physician himself. The same remark applies to atropine, which is an antidote of muscarine, pilocarpine, and digitalis which may come in handy to combat the sequelæ. In some instances we may have to employ injections of normal saline solution to “wash” the blood.

In certain cases of acute delirium, provoked by the false orange, a few leeches to the pit of the stomach or in the mastoid region may assist in subduing the congestive phenomena. Prolonged hot baths are particularly useful in presence of stupor.

To sum up, when we are called to a case of mushroom poisoning, we begin by giving an emetic, followed by a purgative, along with plenty of warm drinks—milk, albuminous water, etc. We must then turn our attention to the ataxo-adyneamic symptoms, delirium, etc., by giving sedatives—ether or chloral, for example, or combat the purely adynamic symptoms, hyposthenia, by ether, coffee, or caffeine, mustard poultices, frictions and so on.

There is an empirical antidote for mushroom poisoning which has of late found favour at the hands of physicians, especially by Dr. Secheyron—viz., powdered charcoal; this is always at hand, and in large doses it neutralises the action of the poisons. Many cases of the kind in the Cevennes seem to show that it is efficacious. We should, however, always begin with an emetic, but the charcoal can be given directly after without neglecting the other urgent measures.

## OPERATING THEATRES.

### ST. THOMAS'S HOSPITAL.

**PERITONITIS CAUSED BY RUPTURE OF AN EMPYÆMA OF THE APPENDIX VERMIFORMIS.**—MR. BATTLE operated on a boy, æt. 9, under the care of Dr. Acland, who had been admitted a few hours previously with acute abdominal symptoms. The patient was stated to have been quite well until 1 o'clock in the morning of admission, when he was awakened by severe pain in the abdomen, and vomited. He was taken to the hospital six hours later, when he was still suffering severely from the pain. His pulse was rapid, and respiration thoracic, and he seemed in much distress from abdominal pain. His abdomen was rigid and very tender, and there was some slight dullness in the right iliac fossa. A few months before this it was stated that he had had an attack of abdominal pain which was not of many hours' duration, but was sufficiently severe to make him stay in bed. When seen by Mr. Battle ten hours after the commencement of the attack, the boy was evidently very ill. His aspect was one of distress, his expression being anxious, his face pinched, and his mouth dry; his pulse was 140, respirations entirely thoracic; the abdomen did not move on respiration; it was tender all over, especially in the right flank, and there was dullness on light percussion over the right flank, iliac fossa, and extending over the pubes. Examination per rectum did not give any information. Mr. Battle expressed the opinion that the patient was suffering from commencing peritonitis, due to disease of the appendix, and he thought the most likely cause for such a very acute condition was a rupture of an empyæma of the appendix. Of the acute conditions starting in the region of the appendix of this formidable type, there were only two which could produce such an amount of fluid in the peritoneum within such a short time, and these were empyæma of the appendix, which had burst into the peritoneal cavity, or the rupture of an appendix abscess into the general cavity of the peritoneum. In the latter instance there would have been a history of some days' illness before the sudden attack, and in this instance the boy was quite well on the previous day, and played about as usual. Operation was performed at once. Pus escaped when the peritoneum was opened, and a considerable quantity of thick pus was found in the pelvis. The appendix was lying

along the brim of the pelvis, was about 4 in. in length, and presented perforation about the junction of the distal third and the remainder, from which purulent fluid was still escaping. The appendix was removed, the peritoneum cleaned by means of swabs and strips of gauze, a rubber drainage tube inserted, and wound closed. When the patient had been returned to bed, he was placed in the Fowler position, and continuous instillation of warm saline in the rectum commenced. A calomel purge was to be given so soon as he had recovered from the anæsthetic. When section was made of the appendix, it was found that the lumen was completely closed by a firm fibrous stricture to the proximal side of the perforation, and it was not possible to pass a probe through it.

Mr. Battle remarked that it was not often that an acute case of appendix trouble terminated so quickly in perforation. He had many times seen an empyæma of the appendix on the point of rupture after several hours of pain, and in those instances the peritoneum contained little fluid, and that not purulent; neither was there any lymph formation on the intestines around the appendix, as there was in the case he had just operated on. The shock in this case was also an indication of the severity of the invasion of a healthy peritoneum. He also considered that this case was another proof of the extensive disease of the appendix which may be found even where the symptoms have been very slight. The incision through the abdominal wall was carried through the middle of the rectus muscle, the fibres of which were separated, this incision being the one which gives a direct access to the iliac fossa, and is less likely to be followed by a hernia in later life than one through the linea semilunaris.

## TRANSACTIONS OF SOCIETIES.

### ROYAL SOCIETY OF MEDICINE.

#### CLINICAL SECTION.

MEETING HELD FRIDAY, OCTOBER 8TH.

The President, A. PEARCE GOULD, ESQ., M.S.,  
in the Chair.

DRS. FINZI and ERNEST SHAW read a further report, and exhibited sections of a case of carcinoma mammae treated by radium, previously exhibited.

Dr. H. WANSEY BAYLEY gave a demonstration of the treponema pallidum in syphilitic lesions, of the spirochæta dentium in carious dentine, and of the spirochæta refringens in balanitis. The demonstration was illustrated with microscopical preparations, using the ultra-microscope.

Dr. J. L. BUNCH showed a case of  
MYCOSIS FUNGOIDES.

The patient was a man, æt. 50, and had been affected for 12 months. The eruption at first resembled eczema, but later diffuse infiltration and granulomatous tumours appeared. There was also considerable pruritus. He had been under treatment since July 23rd, and had greatly improved. An arsenical preparation had been injected hypodermically, and X-rays were used locally.

Dr. DE HAVILLAND HALL had seen a case in which the pharynx and larynx had been affected. No parasitic organism had been discovered.

Dr. H. D. ROLLESTON showed a case illustrating PIGMENTATION OF THE MOUTH IN PERNICIOUS ANÆMIA.

The patient was a man, æt. 25, admitted to hospital for diarrhoea, anæmia, and enlargement of the liver and spleen, in July, 1909. There were patches of inky pigmentation on the mucosa of the lower lip and cheeks, associated with marked freckling of the lower part of the face and round the mouth. No arsenic had been taken previously. The number of red blood corpuscles had varied from 1,515,000 to 3,015,000, the percentage of hæmoglobin from 40.76, the colour-index from 1.17 to 1.5, the leucocytes from 2,960 to 4,000. Only one nucleated red corpuscle had been seen.

Dr. F. W. PARKES WEBER suggested that the

condition might be an incomplete form of Xeroderma Pigmentosa.

Mr. ALBERT CARLESS showed a case of a man illustrating

#### EXCISION OF BOTH MAXILLÆ.

This had been performed first on the left side for a tumour of the superior maxilla growing from the upper part. It was thought to be simple in nature. The operation included removal of a portion of the malar bone, the floor of the orbit, the nasal process of the bone, and ramifications of the growth, which had extended in various directions. Microscopically the growth proved to be an epithelial odontome. The patient did well, but returned five months later for a similar tumour on the right side. The right maxilla was then removed, leaving the orbital plate. For 12 months he had continued well. He had been fitted with a denture by Mr. Alfred Hart, and did not show serious deformity. He could masticate soft food, and complained of little inconvenience.

THE PRESIDENT said he had not had a similarly successful case. He remembered that Mr. Parnell, of Eastbourne, had shown a similar one. Until seeing that one, he had not expected that so little deformity would result.

Mr. JAMES SHERREN showed a case of MECKEL'S DIVERTICULUM CONTAINING CALCULI, PRODUCING SYMPTOMS OF ABDOMINAL COLIC.

The patient, a man, æt. 38, had been operated upon for his third attack of acute abdominal pain. The first attack had been ascribed to gall-stones, the second and third were thought to be appendicular in origin. After the abdomen had been opened in the right iliac region, a sac connected with the ileum and containing calculi was at once detected. It was removed, and was found to be about four inches long, and to be partially closed at its attached end by a valvular opening. It was filled with irregular, brownish, brittle calculi composed of cholesterin, calcium oxalate, and a trace of bile pigment. The patient made an uneventful recovery. Four similar cases were on record, in two of which the stones consisted of cholesterin.

Mr. ALBERT CARLESS said that he had once operated upon a somewhat similar case of a young man suddenly attacked with acute abdominal pain. An incision had been made, as for appendicitis, and an egg-shaped swelling found, connected with the intestine and containing a single mulberry calculus.

Dr. A. E. GARROD said that the appearance of the stone in Mr. Carless's case was in favour of its being a gall-stone. If its colour was due to bilirubin, it could be nothing else. Cholesterin would be compatible with the inflammation of any mucous membrane, and occurred in the urine in cystitis.

Dr. E. I. SPRIGGS showed a case of RHEUMATOID ARTHRITIS WITH ENLARGEMENT OF THE GLANDS AND SPLEEN.

The patient was a male, æt. 16. The condition had begun at the age of 10, and had progressed insidiously until most of the joints had become involved. The vertebral, sterno-clavicular, and temporo-maxillary joints had escaped. Axillary, epitrochlear, supra-clavicular, and inguinal glands were enlarged; and the spleen reached about an inch below the costal margin.

Dr. A. E. GARROD said that he did not consider that there was one disease in children and another in adults. The more generalised reaction in the case of children he thought was merely the usual modification in accordance with age.

Dr. H. D. ROLLESTON said that cases similar to those described by Dr. Still had been previously described in adults by a Continental observer, who had isolated an organism from the glands.

Sir DYCE DUCKWORTH said that he had always regarded the cases described by Dr. Still as manifesting the evidences of a blend of the strumous and rheumatic diatheses.

Dr. O. L. ADDISON showed a case of CHRONIC GLANDERS AFFECTING CHIEFLY THE PALATE AND NASOPHARYNX.

The patient was a carman, æt. 26, whose illness had commenced in August, 1907, with the development of

an abscess in the left forearm. He apparently recovered completely, but in December, 1907, the throat became ulcerated, and the condition had extended until the whole of the soft palate and fauces were destroyed, and the greater part of the mucous membrane of the hard palate. Within the last three months three abscesses had formed in the face and neck, and the hard palate had become perforated. *B. mallei* had been obtained in pure culture from the abscesses, and Straus's reaction was positive.

Dr. G. A. SUTHERLAND showed a case of  
FLEXOR SPASM.

It was that of a girl, æt. 5. Flexion of the fingers into the palm of the left hand had been noticed since June. It persisted during sleep and under an anæsthetic. There was no alteration in the reflexes or electrical reaction.

The PRESIDENT showed a case of

SCHLATTER'S DISEASE OF THE RIGHT TIBIA.

It was that of a girl, æt. 13. Separation of the lingiform process of the upper epiphysis of the bone had occurred, followed by irregular growth of bone in the region of the attachment of the ligamentum patellæ.

Sir DYCE DUCKWORTH read a paper on two cases of  
GOUT.

Case 1 was that of a Mohammedan, and was accompanied by marked tophaceous deposits. The patient had been a cook and addicted to alcohol. Sir Dyce commented upon the rarity of gout in Orientals, and said that it probably never occurred in Mohammedans who kept the rules of their religion. Photographs of the case were exhibited. Patients with much uratic deposit were usually classified as atonic gout, and sometimes enormous deposits occurred without any pain whatever. The condition of the urine may give no evidence of renal fibrosis, but it may contain sugar, and in course of time a diabetic cachexia ensued in some of the patients.

Case 2 was that of a boy, æt. 14, and was also associated with tophaceous deposit. Suppuration had occurred necessitating operation and removal of tophi from the great toe joints of both feet. The only history of gout in the family was that the great-grandfather was a "martyr to gout." The school dietary allowed of only one meat meal a day, and contained no gout-provoking articles.

Dr. G. PHILIP LEE said that he could recall six cases of acute gout in boys of from 9 to 12 years of age, in his practice at Cork.

Sir DYCE DUCKWORTH, in reply, said that gout was very rare in Ireland, and that he was sceptical as to the correctness of the diagnosis in the cases mentioned by the last speaker.

Dr. W. P. HERRINGHAM read a paper based on two cases of

PNEUMONIA, WITH CONSIDERABLE DISPLACEMENT OF THE  
HEART, SIMULATING PLEURAL EFFUSION.

The first case was that of a man, æt. 41, the subject of consolidation of the left lung, in whom, post mortem, the heart was found pushed over so far that the apex was almost in the middle line. In the second case the pneumonia was right-sided, and the signs so much resembled fluid, that a needle was inserted and a little was actually removed. This, as was found later, really came from the lung. A paravertebral triangle of dulness was detected on the opposite side. After death the heart was almost entirely to the left of the middle line. The triangle of dulness might be explained by a marked scoliosis.

Dr. W. EWART asked if, in the first case, the sound lung was hampered in its expansion, so that it could not counterbalance the tendency to enlargement of the pneumonic lung.

Dr. HERRINGHAM, in reply, said that in that case the other lung was quite healthy.

#### Royal College of Physicians of Ireland.

THE annual meeting of the College for the election of officers will be held on St. Luke's Day, October 18th, and will be followed in the evening by the College dinner.

#### CENTRAL MIDWIVES BOARD.

MEETING HELD OCTOBER 7TH, 1909.

The President, Dr. CHAMPNEYS, in the Chair.

A PETITION signed by Dr. S. H. Smith, of York, and other persons interested in the training of midwives in Yorkshire, asking the Board to permit the written Examination to be held at some recognised centre in the county, was further considered, and it was agreed to make Leeds one of the provincial examining centres.

A letter was read from the County Medical Officer for Worcestershire proposing that in cases where a certified midwife sends a notification of still-birth under the Notification of Births Act, the notice required by Rule E. 20 (c) of the Board's Rules should not be insisted upon.

To this the Board replied that it had no power to dispense with any of its rules.

A suggestion from the Clerk of the Hunts County Council that some means should be taken to draw the attention of the public and of uncertified women now practising as midwives that after April 1st, 1910, they will be debarred from so doing, was approved by the Board, who recommended that it should be carried out by the local supervising authority. An inquiry came before the Board from the Secretary of the Miller Hospital, to which are attached extern midwives, as to what course should be adopted on the outbreak of infectious disease in the house of a parturient woman who was attended by a midwife. After much discussion a resolution was passed to the effect that the Board does not see its way to advise in such cases as are not dealt with by their rules and regulations, but that application should be made to the local supervising authority.

Arthur Lionel Hall Smith, M.B., B.C. Cantab., was placed on the list of Supernumerary Examiners to the Board, and approval as Teacher was granted to Septimus Harold Fairrie, M.B., John Murray, M.B., and Edward Bass Reckitt, M.D.

A motion brought forward by Mr. PARKER YOUNG, "That the resolution of the Board of July 23rd, 1908, 'That the Board is not prepared to consider any further applications for admission to the Roll under Section 2 of the Act,' be rescinded," was carried by 7 votes to 2; but the question, which elicited considerable discussion, will come before the Board again for the decision as to what class of midwives are to be admitted and upon what merits.

"That local supervising authorities be not allowed a hearing in penal proceedings before the Board, except by special leave of the Board, which may be given when, in the course of such proceedings, charges are made against an authority, or its officers, to which an answer may be reasonably expected," was carried.

THE SECRETARY reported that £1,737 had been collected from various County and Borough Councils from which fees were due, and that £115 was still outstanding. Referring to those Councils which had delegated their authority, it appeared that in Bristol, where the authority has been delegated to the Watch Committee, the Act is practically administered by the Chief Constable!

MISS PAGET reported on her visit to the Congress of Italian midwives, as the Board's delegate, at Bologna, last month, and the Secretary was instructed to obtain the report of the proceedings of this and all similar Congresses which might occur, and file them in the offices of the Board. A special meeting of the Board will be held on October 28th to discuss the report of the Midwives Act Committee.

#### Royal Institute of Public Health.

A SERIES of lectures have been arranged by the Royal Institute of Public Health with the view to assisting candidates desirous of qualifying for the positions of health visitors and school nurses. The lectures are given on Tuesdays and Fridays at 37 Russell Square, W.C., at 8 p.m.

## CORRESPONDENCE.

### FROM OUR SPECIAL CORRESPONDENTS ABROAD. FRANCE.

Paris, Oct. 10th, 1909.

#### LUMBAR PUNCTURE.

TAPPING of the cephalo-rachidian liquid in the lumbar region is frequently practised to-day to establish the diagnosis of several affections. By this method also, different therapeutic and anæsthetic agents are introduced into the medullary canal. The chief indications of lumbar puncture are, consequently, threefold: anæsthesia, diagnosis, and treatment.

Intra-rachidian injection of anæsthetic agents has been, and is still, says Prof. Tuffier, a point of much discussion.

Many surgeons have rejected it altogether. It seems, however, that this method is capable of rendering service to the surgeon deprived of competent assistance, as frequently occurs in the country, and certain patients with heart disease in whom general anæsthesia is counter-indicated.

Amongst the surgeons who practise this regional anæsthetic, some employ cocaine, while others, the majority, prefer stovaine.

The patient is prepared as for a simple lumbar puncture, and the needle being adjusted to Luer's syringe of two cubic centimetres, 2, 3, 4, or 5 tenths of a centimetre cube of a solution of stovaine at 10 per cent. (the dose varying according to the importance of the operation) are aspired. The syringe containing the solution is separated from the needle and laid on a clean compress, while the needle is used for the puncture between the fourth and fifth vertebræ. About two drachms and a half of the rachidian liquid are drawn and the syringe fixed on the needle with great gentleness so that its position should not be disturbed. If the little manipulation be well done, the pressure of the rachidian liquid will push back the piston, which is immediately arrested in its course by the operator; the liquid mixes with the solution of stovaine, becoming of milky appearance. Gently and progressively the piston is pushed down to the end, when the syringe is withdrawn and the little wound closed with collodion.

Anæsthesia is obtained in about ten minutes after the injection: a sensation of pins and needles is felt in the feet in about three minutes and a certain impotence in the lower limbs which soon becomes complete.

The amount of stovaine to be injected depends on the region to be operated: the minimum dose (2 centigr.) for the perineum; the maximum for the inferior portion of the abdomen, while a medium dose is sufficient for the lower limbs. The anæsthesia lasts half-an-hour or more.

For amputation of the leg or thigh, four-tenths of the syringe are necessary, and for inguinal hernia, appendicitis, enterostomy, five-tenths will be required. Certain precautions are necessary to observe in this method of producing anæsthesia.

The patient should be placed in the lateral decubitus and left for five minutes in this position after the injection, where the operation is to be practised on one or the other side of the body. In weakly persons, the injection should be preceded by an injection of caffeine or strychnine, and particularly in cases of intestinal occlusion or strangulated hernia. After the operation the patient must lie on his back without a pillow.

Rarely is rachi-anæsthesia unsuccessful, but if, after waiting a quarter-of-an-hour, the anæsthesia is incomplete, some error has been made in the introduction of the needle; the stovaine has been injected into the cellular tissues or the muscle. In such a case, the operation must be performed again.

When proper precautions are taken, accidents following this method are rare. They consist in pallor of the face and cold sweats and sometimes vomiting, retention of urine (rather frequent), headache, especially when a sufficient quantity of cephalo-rachidian

liquid has not been previously drawn off, while six cases of sudden death have been reported, all of which were in elderly patients who had received large doses of stovaine.

As means of diagnosis, lumbar puncture finds its indication in numerous affections, to confirm, by examination of the cephalo-rachidian liquid, diagnosis of obscure cases.

The macroscopic aspect of the liquid in its normal condition is absolutely clear as water, in pathological conditions it is cloudy, purulent or hæmorrhagic.

Cloudy or purulent indicates acute meningitis. Hence each time that a patient presents symptoms of acute meningitis lumbar puncture is indicated. When hæmorrhage is perceived in the liquid it may mean blood effused in the subarachnoid space, but it may also originate from the puncture itself, and a distinction is necessary. If the presence of the blood is due to a wound of a vein by the needle, the liquid is red at the beginning and then pales down; if on the contrary the liquid is frankly hæmorrhagic, it is of a brownish or greenish yellow, and not red.

The presence of blood, when confirmed, may be met with in a large number of affections, but it cannot be regarded as an absolute pathognomonic symptom. However, in traumatism of the cranium, it may indicate intra-meningeal hæmorrhage due in many instances to fracture of the skull, and in any case it is a proof that the traumatism is grave.

From a chemical point of view, the cephalo-rachidian liquid is characterised by abundance of chlorides and by traces of albumen. An increase of the latter is, however, an indication of tuberculous meningitis, while the existence of pus denotes acute meningitis. Where ataxy or softening of the brain is suspected, the existence of lymphocytosis will confirm the diagnosis.

Lumbar puncture has been also employed in the treatment of several affections. For the simple purpose of evacuation, the puncture has rendered great services in fracture of the skull by diminishing compression produced by blood effused in the folds of the arachnoid: the coma disappears, consciousness returns, and the headache is relieved by extracting five drachms of the liquid.

Puncture followed by injection of therapeutic agents has been employed with best success in the treatment of cerebro-spinal meningitis. The serum injected may be that of Roux, Flexner, or Wassermann, and the quantity to be used for a child is one ounce, repeated every day for four or five days; two ounces for an adult. About five drachms of the rachidian liquid should be withdrawn before each operation. Other agents have been introduced into the medullary canal such as anti-tetanic serum, collargol, etc., but without great success.

### GERMANY.

Berlin, Oct. 10th, 1909.

#### THE SURGICAL TREATMENT OF BENIGN DISEASES OF THE STOMACH, WITH SPECIAL REFERENCE TO ULCER OF THE STOMACH AND ITS SEQUELÆ.

A PAPER on this subject appears in the *Arch. f. kl. Chir.*, 1/90, by Dr. Max Busch. The writer states that for stenosis from ulcer, as well as for ulcer that in spite of appropriate treatment steadily persists, the treatment by preference is posterior retrotocolic gastro-enterostomy with a double row of sutures. With an ectatic stomach, especially flaccid, he advises Braun's enteroanastomosis as a prophylactic. With an open ulcer he recommends an after treatment that will reduce the acid condition, washing out if necessary, and a careful selection as regards diet. Resection comes into consideration as soon as malignancy is suspected, also in bad callous ulcers, and especially so when the neighbouring organs (liver and pancreas) are encroached upon. The resection should then always be the circular one proposed by Riedel. A good deal here depends on the individual condition as to whether the more radical and formidable operation of resection should be chosen, or the less dangerous gastroenterostomy. The nervous gastric diseases should not be operated on. There are cases,

however, in which one cannot be certain that no ulcer is present without a preliminary laparotomy.

Prof. Neumann has a communication on **PLASTIQUE OF THE OMENTUM IN PERFORATED ULCER OF THE STOMACH AND DUODENUM**, in the *Zeitschr. f. Chir.* 100. He says the indications for plastique of the omentum are practically four in number:—

1. Line sutures for protection and support, as experience has shown that they afford security.
2. For the hollow organs of the abdomen, especially making good defects in the walls of the stomach and intestines, where the defect cannot be remedied by direct suture.
3. For clothing defects in the serous coat, for the prevention of pathological adhesions between abdominal organs.
4. For making new vascular tracts in certain directions (Talma's operation) and for covering the decorticated kidney.

Although the value of the procedure has not yet been proved as regards Nos. 3 and 4, it has on many occasions been of great service in the first and second sections. In operations for ulcers of the stomach good results have been obtained that would have been impossible without it. Nothing else could have replaced it.

One reason why less success has been obtained with it than might have been expected is that the best use has not been made of it. The writer has lately been making use of the method in a way that not only affords the greatest security to the wound, but also furnishes a channel for feeding the patient during the first few critical days after the operation. Ulcers, he says, with not too large perforation openings, in tissues that are not so rigid that closure by suture seems impossible, are simply sutured and the closure rendered secure by stitching the omentum over it. When simple suture is forbidden on account of the rigidity of the adjoining stomach wall, it is advisable to cut away the very rigid part so that the suture can be made through normally healthy tissue, or to make good the defect by transplanting omentum over it. Success will only be attained in this way, however, when the ulcer is not too near the pylorus, and no narrowing of the pylorus has taken place, or is likely to take place from the operation. In such a case in the condition, if the patient allows it, there are three methods for adoption:—1. The opening may be sutured in any way, and gastrotomy performed at the same time. 2. The ulcer may be excised through healthy tissues, and the opening closed after the method of Heinecke-Mikulicz. 3. A transverse section of the pylorus may be made after the method of Billroth I., Kocher, or Billroth II. He considers operation No. 1 as that of choice for such a case, as by it not only are the immediate dangers removed, but the way is paved for affording the best chances for definite recovery from the ulcer. As a rule, however, patients are mostly brought in in a condition in which operation No. 1 is out of the question, let alone Nos. 2 and 3. In these difficulties there are four ways out:—1. Simply to pack the region with gauze. 2. The ulcer can be treated without considering permeability of the pylorus, and nourishment provided for by a fistulous opening in the small intestine. Success has luckily been obtained in both ways, but they can scarcely be recommended when there is suspicion of stenosis of the pylorus. 3. The ulcer can be sutured into the abdominal wall, when the opening can be made use of later for nutrient purposes; or, 4, when this is out of the question, from immobility of the pylorus, a drainage tube may be inserted through the pylorus into the duodenum, the other end passing out through the abdominal opening.

By the latter process the tube is fixed in the opening in a water-tight manner, it passes outwardly in the same safe manner when wrapped round with omentum.

The writer relates how he proceeded in two cases. He makes the suggestion that his omentum plastique should be tried in cases in which the patients are too weak for the severe operations, where the ulcer of the stomach is surrounded by callous edges, or the ulcer

of the duodenum lies too near the pylorus. In this way the dangers of acute perforation are done away with.

## AUSTRIA.

Vienna, Oct. 10th, 1909.

### LUMBAR ANÆSTHESIA.

GROS, at the Prague Verein, gave a history of the method and *technique* of local anæsthesia, which he has practiced in the gynæcological wards during the last year. The total number was 615 operations under this form of anæsthesia; the liquid he kept stored in bottles, according to Höchst, as a 5 per cent. solution of "Novokain-Suprarenan." Half-an-hour before the injection a subcutaneous injection of 0.01 gramme of morphium muriatum and 0.0003 gramme of scopolimin hydrobrom, was used to dull the pain of the deeper injection.

Out of the 615 cases operated on 538 were completely anæsthetised, that is, 87.5 per cent., while 22, or 3.5 per cent., were imperfectly anæsthetised or suffered from pain which caused the suspension of the injection, and therefore he had to resort to inhalation narcosis, but 55, or 9 per cent., were quite refractory. Of these cases 450 were laparotomies; 388, or 86 per cent., were complete; 43, or 9.6 per cent., incomplete, and 19, or 4.2 per cent., complete failures. Of the 165 vaginal operations 150, or 91 per cent., were complete, 12, or 7.2 per cent., incomplete, and 3, or 1.8 per cent., failures. It may be noted here that 100 of the cases were total extirpation of the uterus on account of carcinoma, 74 of myoma, and 37 for affections of the adnexa. The greatest number of failures was in the larger operations, such as laparotomy, and may have been partly due to a faulty *technique*, as it usually occurred after opening the peritoneum, when chloroform had to be resorted to. It may have been due to the pressure in the abdomen influencing the diffusion of the drug. It is worthy of note that the greatest number of failures were met with in young persons; between the ages of 20 and 29 there were 105 cases with 7 failures, or 6.6 per cent.; between the ages of 30 and 39 there were 180 cases with 11, or 6.1 per cent. failures, while in a number of 204 between the ages of 40 and 49 only 3 cases, or 1.4 per cent. were met with; in 93 cases between the ages of 50 and 59 only 1 or 1.07 failed; and in 25 cases between 60 and 80 not one failed.

The after effects were more frequently observed in the young, as 10 per cent. complained of headache, but strange to relate the more nervous suffered least in this respect. One case was followed by paralysis of the abducens nerve, but recovered within two months. In two cases immediately following one another infection had been imported probably through the imperfect sterilisation of the salt solution which sometimes had been substituted by a soda solution in which the instruments had been boiled. Since then the sterilisation has been carried out without any addition of soda. One of these cases died from diffuse purulent cerebral meningitis, the fluid of which contained bacteria coli. The other case had all the typical symptoms of meningitis; by lumbar puncture a cloudy liquor was extracted whose sediment was purulent; in the intracellular matter were found fine rods, but no pathogenic bacilli could be identified. The puncture was repeated four times, and upwards of 80 c.cm. were extracted. On the twelfth day the fever was high, but after this rapidly fell, and the patient finally recovered. No other bad effects were observed from the spinal anæsthesia.

### A CORROSIVE IN THE URETHRA.

Spitzer exhibited a young man who had injected a solution of ammonium chloride in the urethra instead of the ichthyol solution, producing great pain, from which he fainted, followed by hæmaturia and strangury. Later, cystitis and epididymitis followed. Constant erection was so painful that neither bromides nor belladonna could relieve. Subsequently the swelling of the mucous membrane receded after seven weeks, but left strictures and urethral cystitis. With a bougie à boule four strictures along the hard tube can be detected. In the secretions are still found the gonococci.

## FROM OUR SPECIAL CORRESPONDENTS AT HOME.

### EDINBURGH.

**EDINBURGH CHAIR OF SURGERY.**—Professor Alexis Thomson delivered his Introductory Address on assuming the duties of his new office in the McEwan Hall, on Monday, October 4th. He was introduced by Sir William Turner, who paid a sympathetic tribute to Professor Chiene, the occupant of the chair for the preceding thirty years. Professor Thomson, who was enthusiastically received, said that, in undertaking the responsibilities of his position, he was encouraged by the help he had received from his esteemed and venerable teacher, Sir William Turner, and by the loyalty of his colleagues, some of them his former teachers, others his former fellow-students, and among these he was proud to include the new Dean of the Faculty. Dealing at the outset with the history of the Chair, he pointed out that it was of comparatively recent foundation. From 1771 to 1831 surgery was taught conjointly with anatomy. The first Professor of Surgery, John William Turner, officiated for only five years, and was succeeded by Sir Charles Bell, whose researches on the functions of the spinal nerve roots had perpetuated his name. Next came James Miller, the father of Mr. A. G. Miller, now one of the Consulting Surgeons to the Infirmary, who was followed in 1864 by James Spence, a most eminent surgeon and author of a standard work on surgery. Only Spence's imperfect appreciation of the possibilities of antiseptic surgery, which was being introduced towards the end of his professoriate, had prevented his skill as a surgeon from being more fully recognised. Spence was succeeded by John Chiene. Professor Thomson's knowledge of Professor Chiene went back to 26 years ago, when he was one of 300 members of his class. Since ever Chiene became attached to the University forty-three years ago he had been a living force and a tower of strength in the medical school. They honoured him for his teaching and example, and for the service he had rendered surgery in forwarding the doctrines of Lister. In Edinburgh of the "seventies" Chiene was universally recognised as the most ardent and faithful disciple of Lister. The surgery of the present was the product of evolution. In the classical era the practice of surgery and medicine was one; in the Middle Ages the physician retained some of his learning and dignity, while the surgeon was little esteemed, and surgery became a mere handicraft. A new era dawned when John Hunter left his Lanarkshire farm and went to London. Never again since Hunter's day had surgery been dissociated from physiology and pathology, and it was to advance in these essential branches of medicine that the progress of surgery in the first half of the 19th century was due. Surgical anaesthesia (the name they owed to the gifted author of "The Autocrat of the Breakfast Table"), that happiest gift to man, was a debt of the whole world to America and the surgeons of the Massachusetts Hospital. The name of Sir J. Y. Simpson would always be associated with anaesthesia, for he not only discovered the properties of chloroform, but rendered, by his own pen, memorable service in advancing its cause. Lister reformed the whole science of surgery, and it was one of the priceless possessions of their Alma Mater that he had perfected his theory and practice of antiseptics during his incumbency of the chair of clinical surgery. Next to the work of Lister and Pasteur, Koch's researches on the true nature of infectious diseases, and his discovery of the bacillus of tubercle had been the most fruitful of benefit to mankind. It was entirely due to the discoveries made in his branch of knowledge that medical science had come to be recognised as a worthy object of private and public endowment. Encouraging as was the growth of laboratory research no one familiar with the complexity of the problems at issue could suppose that the existing opportunities were adequate for the present and future needs of scientific medicine. They as a profession did not grudge the large expenditure required to maintain the naval and military forces of the Empire, nor the providing in old age for those

who were unable or had honestly failed to provide a competence for themselves, but they did desire that in the huge expenditure with which the country was charged that more should be forthcoming than the beggarly pittance at present granted for the advancement of those sciences on which the health and happiness of the people so much depend. Professor Thomson's introductory address was listened to attentively by a large and appreciative audience, not only of undergraduates, but of his professional brethren and colleagues, as well as of the general public.

**ELGIN COMMITTEE ON THE SCOTTISH UNIVERSITIES.**—Though nothing has been disclosed officially, the London correspondent of the *Scotsman* believes that it may be taken as certain that the report submits a strong case to the Treasury for a largely augmented grant. The total sum involved will, he states, probably involve upwards of £40,000, which is understood to be the figure at which the committee estimate the fair claims of the universities. It is believed that the extra grant advised to be awarded to Edinburgh and Glasgow is about £25,000, the sum mentioned for St. Andrews and Aberdeen being about £9,000 each. It is proposed to increase the salaries of the Principals to £2,000 in the case of the two former, and £1,500 in the case of the two latter universities. These recommendations do not, of course, commit the Treasury, and until they are approved by the Department they cannot be regarded as final.

### GLASGOW.

**A BLOT IN HOSPITAL ADMINISTRATION.**—The Chairman of Dumbarton Parish Council was inclined to blame Lord Advocate Ure the other night for the delay in remedying the condition of things in Dumbarton Poor-house Hospital. It is stated that 11 of the 41 patients there are in a very advanced stage of consumption, and that the present limited accommodation in the hospital necessitates their sleeping and eating with the other patients. The 13 parishes interested have long ago agreed, with the exception of one, to proceed with an extension of the hospital, and it lies with the Local Government Board to compel the non-consenting parish to agree also. Mr. Ure, however, is not a member of the Local Government Board. The Solicitor-General is. Hence Mr. Ure's phenomenal activity in addressing public meetings on the Budget has nothing to do with the case. But the condition of things in the hospital referred to is serious enough.

**DR. ROBERT POLLOK'S BEQUESTS.**—The writing left by the late Dr. Robert Pollok, recommending his residuary legatees, his sisters, to bequeath an endowment of £10,000 to the University of Glasgow for an original research lectureship in *Materia Medica* recalls the fact that he was at one time assistant to the late Dr. James Morton when the latter occupied the chair of *Materia Medica* in Anderson's College. This, we think, was the only teaching in which Dr. Pollok ever engaged. The same writing recommends the endowment with a similar amount of a ward in the Victoria Infirmary. It is stated that these recommendations will be carried out.

**CLOSING OF THE GLASGOW SKIN HOSPITAL.**—The Glasgow Hospital for Skin Diseases closed its doors on the 30th ult., its work having been transferred to the Western Infirmary. The directors are to hand over to the University a sum of £2,500 for the endowment of a lectureship in Dermatology, to be called the McCall Anderson Lectureship, as a memorial to the brilliant founder of the skin hospital, who died a short while since, after devoting fully forty years as physician to that institution.

**MEDICAL SCHOOL BOARD APPOINTMENTS.**—The September post-graduate course at the Glasgow Royal Infirmary has been an unqualified success. In anticipation of the part-time School Board appointments in Glasgow, open to general practitioners, many of them attended the courses of instruction in diseases of the eye, ear, nose and throat, and skin, which enhanced the value of the practitioners' application. It will be recalled that at a meeting of the Central Branch of the British Medical Association, in Glasgow, a resolution was almost unanimously carried, that practitioners were not to apply for the part-time school appoint-

ments, owing to what was deemed inadequate remuneration, but it appears that many who allowed that resolution to be carried without protest have been disloyal to the findings of the Central Branch, and did not withdraw their applications.

**LUNACY REPORT (GLASGOW).**—Dr. Carswell, Certifying Physician in Lunacy to the Glasgow Parish Council, has issued his annual report. From his statistics, which embrace a period of nine years, it would appear that while the proportion of pauper lunatics chargeable to Glasgow Parish was 314.7 per 100,000 of the population in 1901, it has risen to 371.8 in 1908. This increase, however, was accounted for partly by the fact that the increase of lunatics is a natural process with the increase of population. It is pointed out that the real test as to whether insanity is increasing or not is the number of persons who become insane for the first time. Since 1901 this has fluctuated without increasing. The report states that 51 fewer cases were dealt with during the past year, 578 were certified insane, of whom 303 were males and 275 females. Dr. Carswell regards syphilis and alcohol as the most potent causes of insanity from the ages of 25 to 50 years, and considers that syphilis is even more potent than alcohol. 193 patients who were certified insane were over 45 years of age. Dr. Carswell has the distinction of being the first medical man in Glasgow to open the wards in Duke Street Parish Hospital for the reception of insane patients where they undergo a probationary period of treatment before they are drafted to the asylums. In this way many patients recover who are presumably suffering from forms of insanity due to transient causes such as alcohol, and are saved the stigma of connection with asylum life.

#### BELFAST.

**INSPECTION OF MILK SUPPLY.**—The Public Health Committee of the Corporation decided last week to urge the Local Government Board to put into force in Belfast section 19 of part of the Tuberculosis Prevention Act. This would give the local authority power to inspect dairies outside their area, and is exceedingly desirable in the case of a large city like Belfast, a great part of whose milk supply comes from a distance. It is specially with a view to the prevention of typhoid that the order is sought for at present, but of course, it is equally desirable in the case of epidemics of diphtheria or scarlatina in the country.

**QUEEN'S UNIVERSITY.**—The winter session has begun, and the attendance of students promises to be a record one. Scholarship examinations begin on the 21st, and about £3,000 is now offered to the ambitious youth of the province. Of this amount £2,500 is offered by the Senate from the University endowments, and £500 is from private endowments. Lectures begin this week, and the house formerly occupied by the Registrar, Professor Symington, has been converted into a fine suite of rooms for lady students, in which they will have all the amenities offered to the men in the Students' Union, with the exception of a billiard room. The Building Committee of the Senate is busy with the preparation of plans for new buildings, but the rooms most urgently needed—that is, those for the lady students—having been provided, there is time to discuss the plans at length, and do nothing in a hurry.

**THE MEDICAL SOCIETIES.**—A new move has been made in connection with the medical societies meeting in Belfast, which should prove of benefit to all concerned. At the end of last session the secretaries of the Ulster Medical Society, the Ulster Branch of the British Medical Association, and the Belfast Division of the same, were instructed by those bodies to meet and make out a programme of meetings for next session, keeping to Thursday as the recognised day for medical meetings. This has now been done, and a convenient card of "medical fixtures" sent to all members of the three bodies, so that the days of meetings can be kept clear. The autumn meeting of the Ulster Branch will be held on November 17th, in the afternoon, and the annual dinner of the Ulster Medical Society the same evening, so as to give county members an opportunity of attending both.

## LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

#### "THE ADDENDUM PRANDII."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. J. Sim Wallace's paper, which appears in your issue of October 6th, is in many respects admirable, and especially deserves praise for its lucidity. There is, however, one important statement that needs clearing up or more fully justifying. Dr. Wallace declares "that teeth do not decay except when the dietetic régime has brought the mouth into an unhygienic state." I have always held, and still maintain, what, as a student, I learnt from a well-known text-book—that the prime cause of caries is innate structural inferiority of enamel. This tissue varies in density in different subjects between limpid quartz, and sandstone, or chalk; whilst patches of inferior structure, or pits, or fissures allowing lodgment of minute decomposing particles are often found in teeth of otherwise first-rate quality. Oral hygiene, relief of overcrowding with assiduous dentistry will often permanently preserve sufficient members of an inferior set of teeth. On the other hand, given a well-formed jaw and teeth of first-rate structure, and often it will take a lifetime before decay shows itself, even although the owner of the apparatus has never possessed or even seen a tooth brush. Every dental surgeon sees in hospital and private practice illustrations of these facts—patients whose neglected teeth remain sound to the last; patients whose dental tissues are dissolved by the weak acid which the most indefatigable hygiene cannot prevent from being deposited between the teeth or within the flaws of their surfaces. Such flaws often penetrate deeply, and are not until carious visible except beneath the microscope.

I am, Sir, yours truly,

HOSPITAL DENTIST.

London, October 8th, 1909.

## OBITUARY.

WILLIAM RIVERS POLLOCK, M.D. CANTAB., M.D., F.R.C.P.

WE regret to announce the death of Dr. William Rivers Pollock, for many years Obstetric Physician and Lecturer on Midwifery at the Westminster Hospital. Dr. Pollock, who was the fourth surviving son of Mr. G. F. Pollock, formerly King's Remembrancer and Senior Master of the High Court of Justice, was born in 1859. He was educated at Haileybury and Trinity College, Cambridge, where he graduated M.B., B.C., in 1888. Three years later he obtained the Fellowship of the Royal College of Physicians and the M.D., Cambridge, in 1903. Devoting himself to the study of obstetrics, he became Examiner in Midwifery and Diseases of Women to the Conjoint Board of the London Royal Colleges of Physicians and Surgeons, London, and Cambridge University and London University. He held, besides the appointments at Westminster Hospital, the offices of Senior Physician to the Queen Charlotte Lying-in Hospital, Physician to the Grosvenor Hospital for Women and Children, and Professor of Midwifery to the Army Medical College, Millbank. He represented Cambridge in the hurdles in the Inter-University Sports in 1884, winning in what was then the record time, 16sec. Dr. Pollock married in 1889 A. Athol, the daughter of Mr. James Horne Stewart, of New South Wales, by whom he has left a son and a daughter.

GEORGE JOSEPH COOPER, M.R.C.S. ENG., L.S.A., M.P.

WE regret to announce the death of Dr. George Joseph Cooper, M.P., who was taken ill on returning to his house in Southwark Park Road early after leaving the House of Commons, died at 11 o'clock on the 7th October from a stroke of paralysis at the age of 65. There is little doubt that his death was indirectly due to the great strain which has been laid upon members during the present session. Deceased was

most active in the discharge of his Parliamentary duties, being early and late in his attendance at the House. His death deprives the medical profession of a valuable representative in Parliament, for Dr. Cooper was one of the few medical members not content to sink his profession in his politics. It is no secret that his death at this juncture has deprived the next birthday honours list of the name of a member of the medical profession.

Dr. Cooper was educated first at the Leeds Grammar School, and afterwards at Manchester and University College, London. He became a member of the Royal College of Surgeons, England, in 1867, and a Licentiate of the Society of Apothecaries four years later. He was formerly Resident Medical Officer of the Poplar Hospital for Accidents and the Bristol General Hospital. He was a member of the London County Council from 1888 to 1906, and had been Chairman of the Public Health Committee for six years. In 1906 he was elected member of Parliament for Bermondsey by a majority of 1,759 over Mr. H. J. C. Cust, the Conservative candidate. He lived a busy, strenuous life, and conducted a large practice in addition to his public duties.

## SPECIAL REPORT.

### THE FIFTH LONDON MEDICAL EXHIBITION.

The Fifth London Medical Exhibition organised by the *British and Colonial Druggist* has proved as complete a success as any of its forerunners. It was open from October 4th to 8th, and the usual condition of admission was observed, namely that visitors must be members of the medical profession and their immediate friends. As in previous years it was held in the Royal Horticultural Hall, Vincent Square, Westminster. Visitors were received and hospitably entertained by the Editor and staff of the enterprising journal to whose energy this interesting and valuable Exhibition owes its existence. The attendance this year was equal to that on former occasions, and its gratifying nature proved that the conditions were appreciated by members of the medical profession.

The Hall was so full of objects of direct and indirect interest to medical men that it would be hopeless to attempt to deal with them at all exhaustively. Reference, however, will be made to a few of the more prominent exhibits, and if any are omitted it should be clearly understood that the omission is due not to any lack of excellence or other attractive qualities on their part so much as consideration of space and the impossibility of dealing in detail with so great a mass of material.

On entering the Hall the visitor's attention was at once arrested by the handsome stall of Messrs. Brand and Co. There is no need to go at length into the meat essence and other preparations of this well-known firm. Their meat lozenges are well known to travellers, and are now likely to be useful to the aviators. They have a valuable product in Brand's Nutrient Powder, which consists of desiccated raw lean meat; also a fever food for the Tropics, containing essence of beef, cream and yolk of eggs. Another familiar name in connection with nutrients is the Liebig's Extract of Meat Company. At their handsome stall was a collection of exhibits, prominence being naturally given to Oxo and Nursing Oxo, which have gained a great and well-deserved reputation as scientific nutrients. Messrs. Cadbury Brothers were in evidence, as a matter of course, but the excellence of their cocoa and chocolate preparations have long since rendered their name a sort of classic in this particular direction. Their Cadbury's dairy milk chocolate and Bourneville chocolate may be specially mentioned. Publishers were represented by Messrs. Lippincott and Co., Messrs. Frowde and Hodder and Stoughton, and Messrs. Saunders and Co. Gautier Frères had a handsome little stall devoted to their excellent brandy. They represent one of the oldest

firms in the Charente, and their brandy can always be prescribed with confidence by medical men. Messrs. Fairchild, Bros. and Foster displayed their familiar preparations of pepsine and other digestive and nutrient products. Their Panopepton was naturally prominent. There is little need to remind anyone engaged in active medical practice that this product presents lean beef and wheat flour in a readily digestible and absorbable form. Pepsencia may be described as a sort of compound peptic extract. Their bile preparations should also be noted. Messrs. Burroughs Wellcome had a fine stall, full of well-known tabloid brand and other preparations and products, and medical and surgical appliances. We noted in particular their most convenient "Vaporoles," each of which contains a dose of some drug, such as strychnine in a green capsule instantly available for hypodermic administration. Their tabloid thyroid gland is now standardised so that the desiccated gland contains .2 of iodine in organic combination, a most important point in practical therapeutics. Messrs. T. Christy and Co. had a neighbouring stall full of objects of interest, many of these representing preparations familiar as household words to medical men, Glyco-thymoline for instance has a wide reputation in the treatment of catarrh of the throat and nasal mucous membranes. They exhibited a small machine, worked by a pump, capable of turning out about 8 lbs. of block ice per diem and a proportionately greater amount of ice water. The cost is £15, and the action depends on condensation of vapour by means of sulphuric acid. Messrs. Ingram and Royle had a specially artistic stand, showing specimens of various medicinal waters, such as Vichy, Contrexéville (Pavillon), Gies, Wübler, Evian-Cachet, and others with which their name is identified. Messrs. Parke, Davis and Co. made a fine display, amongst other things was the tuberculin ointment for cutaneous diagnosis, introduced by Dr. Ernst Moro. A nodular eruption follows its inunction upon the chest of tubercular subjects. Their mercurettes are composed of metallic mercury made up in solid tablets with cocoa butter, and inunction is performed by rubbing the tablet upon the skin. The various vaccines of the St. Mary's Hospital, officially made by this firm, were on show, together with a large number of other things, elegant, practical, and many of them novel. The famous emulsion of Messrs. Angier was in evidence at another stall. Its published composition is 35½ per cent. petroleum, and 9 grs. of combined hypophosphites of lime and soda, with chemically pure glycerine, to the ounce. Messrs. Bendle, Ltd., have an excellent meat food under the name of Nutrovin. It is palatable, and analysis shows it to contain good materials in amount corresponding to its claims. Jeyes' Sanitary Compounds had their Cyllin compounds to the front at a handsome stall. They showed Cyllin pastilles for the throat, a valuable therapeutic product, Cyllin toilet soaps, and other preparations. Messrs. A. and M. Zimmermann had an attractive display. Among other elegant and useful preparations we noted urotropin, which still holds its ground as one of our most trustworthy urinary antiseptics. Another old friend is beta-eucaine, one of the best of local anæsthetics. Their Sublamin is a non-toxic and non-irritating mercurial preparation. A novel drug is Dr. Carl Spengler's "J.K." curative serum for tuberculosis. The Saccharin Corporation, Ltd., exhibited Novocain, used so extensively as a local anæsthetic, as well as in spinal anæsthesia and dental surgery. Novocain, it should be clearly understood, does not contain cocaine. The same firm showed some exceedingly fine brandy (P.G.B.), specially for invalid purposes. It is a matured brandy procured by distillation from the wine of Spanish grapes, and is sold at a price that should command a wide demand for so sterling a sickroom requisite. The British Diamalt Company showed their product, "Diamalt," which is essentially a malt extract of guaranteed purity and high diastasic value. It is also sold in combination with cod-liver oil. Messrs. Findlater showed a number of table and medicinal waters, among which may be named "Martigny," obtained from a place near Contrexéville, and "Wildungen," a famous German water. "Cara-

banana" is a Spanish aperient water, containing a large proportion of sulphate of soda. Among Messrs. Seabury and Johnson's preparations, were the standard gauzes, packed in airtight sterilised containers. There were the well-known oxide of zinc ribbon plasters, and many other plasters, absorbent cottons, and other things. Emol Keleet is a natural dusting powder, well known to dermatologists for its soothing qualities. This firm also displayed the famous Thermogene wool and California Syrup of Figs. The Anglo-American Pharmaceutical Company, Ltd., showed their well-known preparation, Huxley's Syrup of Acid Glycero-phosphates, which contains pepsin, formates, hæmoglobin, red bone marrow, etc., which has been distinguished by the award of gold medals in various parts of the world. Betul-ol is useful in rheumatic affections. They also showed Fermentactyl, made up with a powerful strain of lactic acid bacillus and introduced by this firm several years ago, that is, before the present boom. Messrs. Menley and James, Ltd., showed "Glidine," a scientific protein food prepared from wheat, which is used as a basis of combination with iron, bromide, iodine, mercury, etc. These various preparations are put up in powder or tablet form, and sold under the names of Iodoglidine, Bromoglidine, Ferroglidine, etc. The corresponding mercurial preparation is named "Lusan." These glidine preparations are worthy of careful trial by medical men. The Maltine Manufacturing Company showed Carnrick's well-known liquid peptonoids, soluble food, and beef peptonoids and powder; also their Maltine, Maltine with cod-liver oil, Maltine with pepsine and pancreatine, Maltine with chocolate, and Maltine with cascara.

The antiseptic plastic dressing now so well known under the name of "Antiphlogistine," and so commonly used by the profession in inflammatory processes, was here exhibited in a very attractive way.

Mr. A. Wander, Ph.D., had an attractive show, with many objects of practical value to medical practitioners. His dry crystalline extract of malt is an excellent preparation, and can be given to children on bread and butter. His chief exhibit was Ovaltine, an excellent nutrient composed of maltine, chocolate, and yolk of egg, which claims to be a complete food. His Formitrol pastilles are excellent in taste and form as an antiseptic remedy for throat affections.

## MILITARY & NAVAL MEDICAL NOTES.

**THE RETIREMENT OF A POPULAR MEDICAL OFFICER.**—The retirement of Brigade-Surgeon Lieut.-Colonel C. E. Harrison, of the Grenadier Guards, and now in command of the Alexandra Military Hospital, Millbank, in the early part of October, cannot be allowed to take place without a few remarks. No more painstaking and courteous officer is to be found in the Army Medical Service. In season and out of it his heart has been, so to speak, in his work, and his dealings with all his subordinates, as well as with his patients, has been uniformly kind, sympathetic, and attentive. No mean responsibility and power are attached to a medical charge and command such as Lieut.-Colonel Harrison has had, and it is much achieved that acknowledgedly he has discharged the duties of his office to the satisfaction of all with whom he has been associated, be they of senior or junior rank. Lieut.-Colonel C. E. Harrison's example of work is worthy of copy by any medical officer. We wish him years of prosperity in his retirement. Although retired he will still be active.

**THE ARMY MEDICAL CORPS AND THE MANŒUVRES.**—The *Brook*, in devoting a leading article to the recent manœuvres, speaks in highly commendatory terms of the Royal Army Medical Corps. There can be no doubt that in recent years this corps has become vastly more efficient, due largely to the opportunities given for practical work.

This was the grave defect of the early nineties; no opportunities were then afforded for practical work on a large scale, and the material was scattered. It is also necessary to say that, with greater opportunities, the *personnel* has acquired more experience—indeed, there is room even for further development.

**INSANITARY MILITARY BARRACKS.**—A short paper appears in the *Naval and Military Record* on the disgraceful condition of some barracks occupied by our troops abroad and at home, founded chiefly on the recent announcement as to the building of new barracks for the British troops at Abbassia, Egypt, on the condemnation of the Kasr-el-Nil Barracks. One has only to look through the annual reports of the Army Medical Department for years back to see that our soldiers, in these days of sanitary enlightenment, are quartered in barracks unfit for human habitation, and live under conditions which would not now be tolerated under civil medical administration. Closely allied to defective barrack accommodation may be mentioned the overcrowding on troopships. There can be no question that this subject should receive immediate attention and reforms be instituted.

## MEDICAL NEWS IN BRIEF

### Opening of Queen Alexandra Sanatorium, Davos.

OUR great national sanatorium in the Alps, for the successful completion of which Mr. H. C. Wrinch, the local secretary, has mainly to be thanked for his unceasing labour, will be open for the reception of patients at the end of this month, although the inaugural ceremony is to be postponed until the winter season. On the visiting staff are the well-known names of Dr. W. R. Huggard, H.B.M. Consul in Davos, Dr. Arnold F. Bill, and Dr. Florian Buol; and the resident staff consists of Dr. Joseph W. Noble as Medical Superintendent, who has had considerable experience in Davos, and Dr. James Fairley as Junior Resident Medical Officer. The Matron, Mrs. Teesdale, who for some years past had the entire management of the Davos Invalids' Home, will be assisted by a small staff of English nurses with home sanatorium training. Although each patient occupies a separate room, the inclusive charge is only 38s. per week. Only early or convalescent cases are eligible. A large number of applications having already come in, candidates should not delay obtaining forms from the local secretary in Davos, Mr. H. C. Wrinch, or from the honorary secretaries in London, Dr. William Ewart, 31 Upper Brook Street, W., and Mr. D. A. F. Vesey, 3 Camp View, Wimbledon Common, S.W.

### State Insurance.

On the agenda for the annual meeting of the National Conference of Friendly Societies, which is to be held at King's Lynn on the 14th inst., is the Committee's report on the proposed scheme of State insurance against sickness, invalidity, etc. The Committee doubt whether it would be wise to join in an agitation against any proposals which lay down the principle that a working man shall make provision for himself, and those dependent on him in the days of health and prosperity by joining one of the sound friendly societies of the country, with the alternative that if he will not do so he shall be compelled to contribute to a Government fund. The Committee declare that they have, instead of organising a fruitless campaign such as that waged against Old Age Pensions, given their best services to ensure that the State scheme, if legislation is to come, shall be made a powerful auxiliary to sound friendly societies. In the absence of the detailed scheme, however, it would be wise to withhold a final judgment.

We regret to learn that Major J. C. Massy Wheeler, a well-known Indian officer attached to the 84th Punjaubis, has died in a private hospital in London while under an anæsthetic.

## NOTICES TO CORRESPONDENTS, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

### SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, £1s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs 15.12. Messrs. Dawson and Sons are our special agents for Canada.

### ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £3 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

EXAMINER (Staffs.).—(1) For the rapid and accurate microscopical examination of urine under the circumstances you describe, a centrifuge is indispensable. (2) We have found, on the whole, the cold nitric acid test the most convenient and trustworthy for the detection of albumin.

M. H. O. (Lincs.).—The slurring speech of intoxication and of general paralysis of the insane have a somewhat close slurred resemblance. Syllables are dropped and the words shortened—for instance, Mr. British Policeman becomes "Miss'r-Bri-sh-p'leesh'm'n."

RADIUM.—It has been lately stated that the price of radium has been artificially enhanced. Any leading surgical instrument maker ought to be able to procure the apparatus required.

A LAY READER.—We do not give medical advice or prescribe in these columns. To our present correspondent we can state that "hair falling off" may be due to several distinct causes, local or constitutional, or both combined; and any one treatment professing to cure all these conditions is, on the face of it, fraudulent. They can only be treated properly by qualified medical men.

STUDENT.—A dental surgeon needs, before everything, to be a first-rate handcraftsman. Unless he is a good operator, he cannot succeed. No academic distinctions will avail without this prime accomplishment.

## Meetings of the Societies, Lectures, &c.

WEDNESDAY, OCTOBER 13TH.

UNITED SERVICES MEDICAL SOCIETY (Royal Army Medical College, Millbank, S.W.).—8.30 p.m.: Lieut.-Colonel P. J. Freyer, I.M.S. (R.): Total Enucleation of the Prostate; Practical Observations on the Operations.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. T. Walker: Clinique (Surgical). 5.15 p.m.: Lecture: Dr. G. H. Savage: Moral Insanity.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Clinics: 2.30 p.m.: Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 p.m.: X-Rays (Dr. H. Pirie).

THURSDAY, OCTOBER 14TH.

ROYAL SOCIETY OF MEDICINE (OBSTETRICAL AND GYNÆCOLOGICAL SECTION) (20 Hanover Square, W.).—7.45 p.m.: Presidential Address: Dr. H. Macnaughton-Jones. Dr. J. M. Munro Kerr: A Case of Placenta Prævia in which it was deemed advisable to perform Cesarean Section. Dr. J. Curtis Webb: Points on the Use of, and Indications for, Electro-therapy in some Gynæcological Affections.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Sir Jonathan Hutchinson: Clinique (Surgical). 5.15 p.m.: Lecture: Mr. L. Mummery: The Diagnosis and Treatment of the More Serious Forms of Colitis.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. A. E. Giles). Clinics: Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 p.m.: Medical In-patient (Dr. G. P. Chappel). 4.30 p.m.: Lecture: Mr. W. Edmunds: Surgery of the Blood Vessels.

FRIDAY, OCTOBER 15TH.

ROYAL SOCIETY OF MEDICINE (ELECTRO-THERAPEUTICAL SECTION) (20 Hanover Square, W.).—8.30 p.m.: Presidential Address: Dr. Samuel Sloan: Electro-therapeutics in Gynecology.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE (11 Chandos Street, Cavendish Square, W.).—8.30 p.m.: Discussion on Recent Advances in our Knowledge of Sleeping Sickness.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5 p.m.: Prof. Keith: Specimens illustrating Various Forms of Constrictions and Occlusions Found in the Course of the Alimentary Canal. (Museum Demonstration.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. W. Stuart-Low: Clinique (Ear, Nose, and Throat).

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Operations. Clinics: Medical Out-patient (Dr. A. G. Auld); Eye (Mr. R. P. Brooks). 3 p.m.: Medical In-patient (Dr. R. M. Leslie).

TUESDAY, OCTOBER 19TH.

W.C.).—3.45 p.m.: Lecture: Mr. Chicbele Nurse: Middle Ear Labyrinth.

## Appointments.

COOKE, CHARLES JAMES, M.D., M.Ch., B.A.O.R.U.I., Medical Officer to the Board of Trade at Plymouth.

DESPREZ, H. S., L.R.C.P. and S.Edin., L.F.P.S.Glasg., Certifying Surgeon under the Factory and Workshop Act for the North Tawton District of the county of Devon.

EDWARDS, A. H., M.B., C.M.Edin., F.R.C.S.Edin., Dispensary Surgeon to the Western Infirmary, Glasgow.

GRANT, ROBERT, M.D.Aberd., Certifying Surgeon under the Factory and Workshop Act for the Cromer District of the county of Norfolk.

NICOL, J. W., M.B., C.M.Glasg., Physician for Skin Diseases in the Western Infirmary, Glasgow.

NORMAN, VINCENT P., L.M.S.S.A.Lond., Clinical Assistant to the Eye Department of the West London Hospital.

POIGNARD, R. N., M.B.Cantab., Certifying Surgeon under the Factory and Workshop Act for the Littleport District of the county of Cambridge.

TOMKINSON, J. G., M.D., Ch.B.Glasg., Physician to the Skin Dispensary of the Western Infirmary, Glasgow.

## Vacancies.

City and County of Nottingham.—Assistant Resident Medical Officer. Salary £130 per annum, with apartments, board, washing, and attendance. Applications to G. Muncaster Howard, Clerk to the Board, Poor-law Offices, Nottingham.

Royal Edinburgh Asylum.—Junior Medical Officer. Salary £125 per annum, with board, residence, and laundry. Applications to the Medical Superintendent, Royal Asylum, Edinburgh.

The Princess of Wales's General Hospital, Tottenham, N.—House Surgeon, £75 per annum; House Physician, £75 per annum; Junior House Surgeon, £40 per annum; Junior House Physician, £40 per annum; with residence, board, and laundry. Applications to Fredk. W. Drewett, Director. See advt.)

Nottingham General Dispensary.—Assistant Resident Surgeon. Salary £160 per annum, with apartments, attendance, light, and fuel. Applications to C. Cheesman, Secretary, 12 Low Pavement, Nottingham.

Lincoln Mental Hospital, The Lawn, Lincoln.—Assistant Medical Officer. Salary £150 per annum, with board, etc. Applications to the Medical Superintendent.

Brighton, Hove, and Preston Dispensary (Northern Branch).—Resident Medical Officer. Salary £160 per annum, furnished rooms, coals, gas, and attendance. Applications to the Assistant Secretary, 113 Queen's Road, Brighton.

Birmingham General Dispensary.—Resident Surgeon. Salary £200 per annum, including cab allowance. Applications to Ernest W. Forrest, Secretary, 32 Union Street, Birmingham.

Westminster General Dispensary.—Resident Medical Officer. Salary £120 per annum, with rooms, gas, coal, and attendance. Applications to the Secretary, 9, Gerrard Street, Soho, W.

The Children's Hospital, Temple Street, Dublin.—House Surgeon. Salary at the rate of fifty guineas per annum, with extras. Applications to Hon. Secretary, Medical Board. (See Advt.)

## Births.

GERRARD.—On Oct. 5th, at 28 Church Road, Richmond, Surrey, the wife of Lieut.-Colonel J. J. Gerrard, M.B., R.A.M.C., of a son.

HUME.—On Oct. 5th, at Lahore, India, the wife of Norman H. Hume, Indian Medical Service, of a son.

MINOCH.—On October 4th, the wife of William C. Minoch, M.D., 4 Kenilworth Road, Dublin, of a son.

PEACOCK.—On Oct. 6th, at Steeple Aston, Oxon, the wife of Dr. W. E. Peacock, of a son.

## Deaths.

CARNEGIE.—On Oct. 1st, at Darlington, Douglas John Carnegie, M.A.Cantab., son of the late John Carnegie, M.D., of Chesterfield, aged 46 years.

CARTER.—On Oct. 5th, at Billericay, Essex, Frederick Carter, M.D., J.P., in his 69th year.

WANSTEAD.—FINE CORNER POSITION, SUIT MEDICAL GENTLEMAN.—Six bed and dressing rooms, bath room, five reception rooms. Large garden. Price freehold, £1,250. Apply Messrs. Protheroe and Morris, 67 and 68, Cheapside, London, E.C.

# THE MEDICAL PRESS AND CIRCULAR.

WEDNESDAY, OCTOBER 20, 1909.

No. 16.

## NOTES AND COMMENTS.

**The Suffragettes and Lunacy Statistics.** IN a recent issue we hinted our doubts of the mental sanity of any woman who deliberately attempted to starve herself to death because a Parliamentary franchise was not granted to her sex. Nor is it easy to imagine any more flattering explanation of the psychical power that transforms a gentle, well-bred woman into a raging propagandist, smacking the faces of policemen, shrieking, tearing, scratching, biting, cutting down barricades with axes, smashing windows and hurling down tiles from rooftops on the heads of innocent bystanders. Surely and of a truth that way can hardly be sanity. Yet the lunacy returns of the London County Council do not point to any marked increase of insanity amongst women. On the other hand, they show that there is apparently a great increase of insanity among the population year by year, and the increase is greater among the men than among the women by 4 or 5 to 1. The Asylums Committee of the Council say in so many words they do not think there is any reason to conclude there is any great real increase of insanity. The Suffragette, however, is not likely to be hindered by any cold reasoning of that kind from her conclusion that men are getting madder than women by 4 to 1, and that the whole population is getting madder every year, so that the ascendancy and survival of the saner sex—to wit, woman—is only a question of time. By the way, many of these male lunatics have been kept alive by forced feeding, what view do the Suffragettes take of the ethics of that asylum procedure? Should the patients be released, fed by tubes, or allowed to die in their own way?

**The Humour of the Situation.** WHAT is to be the alternative to forced feeding in our criminal prisons? If a precedent is to be adopted in the case of Suffragette offenders, it must be generally applied, for the law makes no distinction of persons. Both points may be seriously put to the medical gentlemen who have publicly stated, in effect, that there are certain undefined dangers attached to that method of keeping refractory prisoners alive. Authority is dear to the feminine mind, and on the strength of that professional pronouncement every Suffragette in the United Kingdom is ready with dark suggestions and forebodings as to the ill-effects of forced feeding. No amount of authority, however, is likely to convince the trained professional mind that there is any

substantial danger involved in the introduction by a skilled medical man of fluid nutriment into the stomach by means of a soft rubber tube and a funnel. We can say on incontrovertible information that in the prisons of the United Kingdom such feeding is invariably administered by the prison medical officers, and that the stomach pump has long ago been discarded in favour of the soft tube and funnel. The amount of risk present under those conditions is of the smallest, and certainly nothing at all to be compared with the deaths that follow, let us say, abdominal or brain operations. For all that one would imagine from the outcry that has been raised in certain quarters that prison feeding should be regarded as one of the most serious capital operations of the surgeon. If there be any such attendant risk it should surely be demonstrated beyond cavil to the medical profession. Meanwhile, the humour of the situation is worthy of the pen of a Rabelais.

**A Representative Hospital Fund.** THE yearly appeal of the Metropolitan Saturday Fund is interesting in various ways. The pioneer of this great movement towards the co-ordination of medical charity, has now reached its thirty-fifth year of existence. The organisation has to a great extent retained the support on which it was originally based, namely, that of the working classes. Its watchword may truly be said to be "Self-help," and the spirit of the Saturday Fund has infused the friendly societies, the workmen's clubs, and the employees of post office, London County Council, and almost every large business undertaking, whether Governmental, municipal, or private, in the metropolis. Early in the present year a sum of £27,332 was distributed among the metropolitan hospitals and kindred institutions, a larger sum than had ever before been disbursed. There are several reasons why the Metropolitan Saturday Fund deserves the support of all who are interested in the solid progress of medical charity. First and foremost we should place the vital fact that its control is purely representative. It is, in fact, governed by a joint board of representatives from the contributors and from the hospitals. This constitution contrasts sharply from that of the Sunday and the King Edward VII. Funds, both of which are practically ruled by a knot of irresponsible persons, with the inevitable risks of a resulting arbitrary, inconsistent, and it may be at times even an unfair policy of administration. The second great virtue of the Saturday Fund arises indirectly from the former, namely, that it is an ardent supporter of the hospitals, the representatives from which get on the board.

**Why Should  
not the  
Funds be  
Under  
Popular  
Control?**

It is difficult to understand how any great public body, more especially one that has to deal with vast sums of money, should object to the principle of popular representative control. Any other method smacks of mediæval times, and is absolutely out of touch with the character of the bluff Englishman, who always has, and always will in the long run, insist on having a voice in the spending of his money. As things stand the two younger, and reputed wealthier Funds, are governed by councils in which philanthropy (in some cases of the professional order) and the great hospitals have an undue influence. It is not more than fifty years ago that the Royal College of Physicians of London were asserting their claim to hold all the hospital appointments in London. The last fight against that absurd claim of privilege took place over St. Mary's Hospital. Nowadays the College keeps a tight grip over most of these posts by the condition that is imposed in the hospital laws demanding a higher qualification of the London College as a necessary condition of candidature for a physician's post. The large hospitals are to-day strongly represented on the King Edward VII. and the Sunday Funds, but not the less important ones. Is there any solid reason why this should be the case? What are the views of those two great Funds as to the practical monopoly of the big hospital posts by the holders of London College diplomas to the exclusion of the Scotch and Irish, not to mention a whole sheaf of University degrees?

**Kingston  
Medical  
Officer of  
Health.**

A PROPOSAL has been started to promote a public testimonial to Dr. Collins, the Kingston Medical Officer of Health, in recognition of his sixteen years' service. The movement seems to have been promoted by the fact that the Town Council, at a meeting held *in camera*, decided to reduce his salary by the sum of £55 a year. No public explanation has been offered as to this unusual procedure; the only complaint that has ever been made concerning Dr. Collins is, that he is too zealous in carrying out his duties, and particularly that he recently recommended the alteration of certain schools in the borough which would have involved considerable expense. There seems no reason to doubt the truth of this story. It illustrates once more the deplorable position of the average medical officer, so often discussed in these columns. The testimonial will no doubt gratify Dr. Collins; but it would have been more satisfactory to him, and very much better for the borough, if the burgesses of Kingston had displayed a due amount of local patriotism, and had so ordered things that the Town Council should not be dominated by men capable of thus gratuitously venting their spleen upon a capable, conscientious, and trusted public servant.

**The Quality  
of Borough  
Councillors.**

THE Borough Council elections, all over the country, are held next month, and it depends everywhere upon the quality of the men elected as to how much of the mass of legislation devised to promote social reform and progress shall be carried out. The wisdom and zeal displayed in working sanitary laws, disregard of which inflict the greatest hardship upon the poor, vary widely in different districts; in few are the laws rigidly enforced; in many they are almost completely disregarded. The Bishop of

Stepney and Canon Barnett delivered weighty speeches on this subject last week. The Bishop gave his experience as a vestryman and guardian some years ago, and referred to the apathy of the public in local affairs; they were astonished and horrified when a public scandal was unearthed, but would not cross the road to vote at an election. Local government ought to be kept free from party feeling. What are wanted on local bodies are earnest, public-spirited men, but these will not come forward without encouragement and support from the mass of electors. Democratic institutions cannot be properly worked unless all that is good and best among the citizens will directly or indirectly take part; at present they are not, as a whole, performing this duty, and their apathy constitutes a serious danger to the commonwealth.

**Court Fees  
Before or  
Not Before?**

"GET your fee before you are sworn" is no doubt an admirable maxim for medical men who live in the country far from the maddening crowd, where the incidents connected with their practices seldom get into the hands of lawyers. It is a little doubtful, however, if it is wise for practitioners in the larger towns to adhere closely to the same rule in medico-legal cases. To demand money down under such circumstances would be never ending, for modern legislation binds up medical matters more and more in Acts of Parliament; the motor car has made the old common law "running down case" a normal occurrence *de die in diem*; sanitary and feeding questions are arising in every town. Now all these things are the bones of legal medicine, which no longer simply comprises murder, rape, and lunacy, as the forensic medicine books would have us believe. There is, accordingly, a large and lucrative branch of practice open to the general practitioner in London and provincial centres as real as midwifery, and far less exhausting. When a man beginning practice sits down behind his brass plate he does not say to the first patient who comes, "Your fee first," and it is for every practitioner, in places where medico-legal work is likely to be fairly plentiful, to consider whether he will say it to the first solicitor who comes to him. It is very certain that a medical man who can be trusted by solicitors to give them sound scientific advice and explanation in cases involving medical knowledge will not so very much regret, in the long run, a few cases in which he has not been paid his fee. A solicitor is a business man, and is very unlikely to be mixed up in a series of cases where, in the end, there is no money at all.

## LEADING ARTICLES.

### RELIGION AND MEDICINE.

THE sole legitimate function of religion in relation with the practice of medicine is to bring to the sick and suffering fortitude, patience, hope, and consolation. This fact, which has been always insisted upon in these columns, will, it seems probable, continue to be accepted by the vast majority of the Anglican clergy. After all, an average English parson is mainly dominated by common sense, in spite of the theological bias to which his often too narrow education and training may tend. It is not, therefore, surprising to find that the effort made by a small section of the Church to trespass beyond their proper domain is not apparently gaining much support. The meeting held last week of the Church and Medical

Union was very poorly attended, and the Union can so far boast of not more than eighty members all told. The idea underlying and stimulating the activities of the members seems to have been summed up by one of the speakers. He declared "that there was a positive side to Christian Science, but that the first requisite was knowledge, which the Union intended to obtain, and give from the theological and medical standpoints." We agree that there is a positive side to Christian Science—a side of positive nonsense. This is the side that expresses the belief that diseases of every kind are distinct entities which can be expelled from the system by processes of mediæval thaumaturgy. All will agree that the requisite in dealing with disease evidently is knowledge in the form of a due acquaintance with physiology and pathology—the working of the human organism in health and under the action of morbid influences—knowledge which Christian Science repudiates or ignores. From the medical standpoint, and from the standpoint of everyone with a rudimentary knowledge of the fundamental problems, the question in every case of mental and physical suffering is first the question of diagnosis, what is the nature and true cause of the malady. In a certain number of cases the patient must, in the main, minister to himself. It is beyond the power of a physician to pluck from the memory a rooted sorrow, or to cleanse the bosom of that perilous stuff that weighs upon the heart. Such cases may well frequently seek and find consolation solely in religion; but it is nevertheless the physician's duty in every case that comes before him to make out as certainly as possible whether or not there be any physical basis for the trouble, or any functional disturbance due to it. He has always to consider what treatment may be required for functional disturbances arising from purely mental causes. Medicine takes full cognisance of the mutual influence of mind and body; and a change of climate, a change of habit, a course of baths, and a special dietary are all much *materiæ medicæ* as any common drug in the *pharmacopœia*. It must, however, be borne in mind always that the majority of cases in which mental depression of any kind forms the most prominent symptom are associated with pathological conditions, and to hand over such cases indiscriminately to purely spiritual ministrations would be to condemn most of them to prolonged suffering or to death. It would be easy to fill pages with illustrations of this fact; they are not necessary to the medical reader, but need forcibly presenting to religionists who, like the members of the Union, seem to have too much faith in what they designate as "spiritual healing." Take the cases of women first. In a vast number of these mental trouble is due entirely to disorder or disease of the organs of generation. This may be anything between simple *dysmenorrhœa* and organic ovarian disease, or cancer of the uterus. Women are prone to conceal these maladies, but unless discovered and promptly dealt with by the physician the result is frequently

disastrous, whilst no mental or moral influence can in the least interfere with their course. The same consideration applies to many other maladies affecting either sex. Many subtle organic diseases display mental depression as their most prominent or even single sign; many of them are amenable to medical art, and to this alone. In all phases of disease the mental state has its share in maintaining vitality; and no proof or illustration is needed of the power to withstand pain and to prolong life that is given to the patient who wills to live, and knows how to bear his suffering without fretfulness and useless complaint. The minister of religion, when he can induce such a state of mind, is performing the greatest service that his office allows of—and with this he surely may well be satisfied.

## CURRENT TOPICS.

### The Sale of Arsenic.

THE sale of arsenic in the United Kingdom is hedged in with many and minute precautions, indeed, it has a special Act of its own, but for all that there is room for improvement. The sale of arsenic for medical use is restricted to qualified chemists, who must enter the name and address of the purchaser, the quantity of the drug, and the purpose to which it is to be put, and other precautions. On the other hand, arsenic can be bought and sold freely by anyone in the shape of sheep dips, insecticides, or other horticultural and agricultural purposes. There can be little doubt that a levelling up of the Poisons Act would decrease the number of deaths resulting from arsenical preparations. It is well known that the extra precautions placed on Part 1 of the schedule to the Poisons Act have reduced the deaths from the more deadly poison in that class until they are actually less than those in the second or less dangerous class. It is well to remember, in connection with further amendment of the Act, that arsenic is actually sold at the present moment in certain notorious quack medicines, and that it may be bought freely in certain combinations put up by respectable drug firms, who print the formula and add a poison notice on the label. For all that, the fact remains that large and dangerous amounts of arsenic may be readily purchased in that form. Then, again, this deadly substance occurs in certain cancer pastes and in depilatories. We are of opinion that the use of arsenic in patent medicine should be prohibited under heavy penalties, and that it should not be sold in any proprietary medicine, formula or no formula, and should be dispensed by the chemist only on the authority of a recent and properly verified medical prescription.

### The Insurance of Motor Cars.

WE are very pleased to learn that the Insurance Committee of the British Medical Association has undertaken for the future "Motor Insurance" in addition to its other insurances. A company whose policy offers undoubted advantages has been selected, and, for the future, members of the Association will be able to obtain this policy at a dis-

count of 10 per cent. The terms of the policy, as we have said, appear to be most advantageous, but there is just one other point on which we think that the Insurance Committee should inform their prospective clients. The company in question is a most reputable one, and, during the time for which it has been in existence, it has, as we know from personal experience, given the utmost satisfaction to its clients. We believe, however, that it is a company which is owned by a few private individuals, and we have heard a doubt expressed as to whether, in the event of its being involved in financial difficulties owing to exceptionally heavy claims against it, its association with the name of "Lloyd's" would be of any practical value. It is a very serious matter to undertake the payment of all claims—unlimited in amount—for any injuries which may be inflicted by a number of motor cars on third parties. The number of cars insured will presumably be large, and the claims which might accumulate against the company in the course of a few days owing to untoward circumstances might be very heavy. We think, then, that it is the duty of the Committee to assure themselves of the financial backing which is behind the company, and to see that proper guarantees are given. The members of the Association should then be informed that this has been done. The step is none the less proper because, in this particular case, the *status* of the company may render it unnecessary, and we hasten to add that we are confident that such is the case. Ordinary business securities, however, cannot go on trust, and if the Committee wish to make their scheme a success they must take the course suggested. If they have already taken it, then they must announce the fact.

#### Some Dangerous Domestic Remedies.

THE evils of amateur doctoring were well shown at a Bolton inquest last week when a little child of three years died after her mother had administered four drachms of sweet nitre at her husband's suggestion. Medical evidence was given to the effect that the proper dose at that age was 12 drops, and that an overdose might result in heart failure. In adults the dose of 4 teaspoonsful might cause unpleasant, if not dangerous symptoms. Another remedy often used for a "cold" is spirits of camphor, a drug which is exceedingly dangerous in over dose. Both saffron and arnica are also apt to produce untoward symptoms when given internally. There are undoubtedly many infantile deaths caused by the administration of paregoric and medicines containing narcotics. The greatest havoc, however, follows the use of patent medicines of the class of soothing syrup, balsamic cough mixtures, pectoral balsam, and the rest, as well as by "teething" powders, which almost invariably contain mercury, and often set up convulsions and fatal gastric enteritis in children. As a matter of fact, it seems probable that not more than a small percentage of these deaths is attributed to its real origin. The risks involved in drugging children, even by apparently quite homely and simple remedies, are indeed great. Government might decrease the harm a good deal by insisting that

every proprietary drug should carry its formula on an outside label. Every wise housewife will confine herself to some half dozen remedies, such as magnesia, salts, castor oil, and liquorice.

#### A Receiving House for 'Lunatics.

AN important departure has been taken by the London County Council in dealing with lunatics. It has been resolved, upon the recommendation of the Asylums Committee, to establish a receiving house, wholly staffed and supervised by their own officers. The intention is that an alleged lunatic, pending lunacy proceedings, should be taken to the receiving house, where he could be retained by the medical superintendent for a period of three days, at the end of which time the alleged lunatic would either be discharged or brought before a magistrate. The superintendent would then report to the justice whether in his opinion the alleged lunatic should be sent to an asylum or detained in the receiving house. If the justice doubted that the case called for special asylum treatment, the usual proceedings under the Lunacy Act would be taken. The Council resolved that an application should be made to Parliament in 1910 to give effect to this proposal in the County of London. The step is one of considerable importance in dealing with mental disease. It substitutes scientific and skilled observation and treatment to the present haphazard system, whereby in some instances a grave injury has been inflicted upon the public as well as upon individuals. In dealing with the maladies of a large population like that of the metropolis classification and centralisation become essential principles of efficient administration.

#### The Effect of the Anti-Tuberculosis Movement on Irish Industries.

IT is well known that a great deal of the difference of opinion regarding the benefits or otherwise to be derived from the Tuberculosis Act, Ireland, is due to a very widespread opinion that the movement which resulted in the Act has also resulted in inflicting a great deal of harm on Irish industries and on the wage-earning capacity of the Irish people. It is therefore interesting to learn from a letter in the daily press from the pen of the Chairman of the Killarney branch of the Women's National Health Association that this opinion is not based on fact. The writer consulted various sources in order to obtain evidence as to whether the movement had affected (1) the tourist traffic in Ireland; (2) the sale of Irish industries; or had (3) been the means of preventing Irish people from obtaining employment in England. The general, and almost universal, trend of the answers received has been to show the contrary is the case. Messrs. Cook, the tourist agents, say that they have not heard of a single instance of a tourist being debarred from visiting Ireland because of the existence of the anti-tuberculosis campaign. The Wholesale Irish Lace Depôt report an increase in their trade, and a number of large English firms, such as Whiteley's and Harrod's say that, so far as they are concerned, there is no truth in the report that Irish men and women are not employed by them. It is, of course,

"cures" for, say, incurable kidney disease, or to destroy health and life by dangerous drugs sold by lying promises to cure this, that, or the other malady, or, haply, some four or five score assorted diseases? Nor is wonder lessened when we find that in religious or semi-religious journals the quacks find their securest stronghold. Why should not a self-respecting lay editor refer all advertisements of "cures" and remedies to a competent medical sub-editor?

An American newspaper, to its honour be it said, has excluded offensive medical advertisements from its columns. This step of the *St. Paul Pioneer Press* has been taken at considerable financial sacrifice, and the *St. Paul's Dispatch* later announced that it was going to "clean up its columns." This action was warmly commended by the *Journal of the American Association*. (a)

Another journal that has made an honourable stand against quack remedies is the *Australian Traveller*, the organ of the Commercial Travellers' Association of Australia. It is published by a body of business men representing all branches of commerce, and it deliberately refuses to make money out of quack remedies or drugs that "debauch and deprave."

They announce prominently:—

WE REFUSE THEM.

IMPORTANT NOTICE.

This paper will NOT advertise  
any MEDICINE (or the proprietors of)

Claiming to CURE:—

CANCER,  
CONSUMPTION,  
or other

ORGANIC DISEASE,  
DISEASES OF THE NERVOUS SYSTEM,  
BLOOD DISORDERS,  
FEMALE COMPLAINTS,  
NERVOUS DEBILITY.

Finally, when the time comes that the prosecution of irregular practitioners and of fraudulent remedies is systematically conducted by some responsible official, the risk to newspaper editors of being indicted for assisting in a criminal transaction, will, in all probability, speedily cleanse the British Press of this blot upon its escutcheon.

#### THE MEDICAL PROFESSION AND THE CLEAN NEWSPAPER.

The aggregate influence of the medical profession is enormous. If its members gave their united support to the clean newspapers, and denied it to those who inserted objectionable advertisements, there is little doubt they could make or mar the fortunes of many a journal. With this end in view, it would be, perhaps, feasible for the medical journals, or the British Medical Association, to publish a kind of *index expurgatorius*, marking the newspapers that medical men are advised to reject on the score of the insertion of objectionable advertisements; or, alternatively, perhaps the wiser plan would be to point out the journals free from reproach in that particular direction.

#### CORONER'S INQUEST.

The coroners admittedly exercise a good deal of influence in the control of quacks and quackery. By means of a direct object-lesson they are often able to assist in opening the eyes of the public as to the evils of the system. Indirectly they might greatly help in the suppression of quackery were they to hold more frequent inquests in cases of uncertificated deaths, and to maintain, if they have the necessary legal powers, a watchful eye upon the signatures to death certificates accepted by local registrars.

Coroners may do good in various ways, as shown

(a) May 15th, 1909, p. 1,589.

in the following case, which illustrates the use of a quack medicine for epilepsy. The inquiry was held by Mr. Braxton Hicks, upon the body of a journeyman baker, a sufferer from epilepsy, who spent 11s. weekly on patent medicine. This costly stuff was shown by medical evidence to consist of chloroform water, coloured by burnt sugar, and a few grains—an absolutely useless dose for epilepsy—of potassium bromide. The jury appended to their verdict of "Death from natural causes" a rider to the effect: "That they considered that the attention of the proper authorities should be called to the gross fraud perpetrated upon the public by the sale of these mixtures at exorbitant prices." The first obvious reflection on reading this rider is to ask, "Who are the proper authorities? Do any such authorities exist? Whose duty is it to take action on the indignant protests that come from the coroners and the criminal courts?"

#### THE REGISTRAR-GENERAL.

The Registrar-General can make it much more difficult for irregular medical practitioners to carry on their work if he insists upon a stringent rejection by local registrars of all signatures to death certificates other than by duly qualified medical men. In view of the varying practice and laxity that is from time to time revealed in newspaper reports, some official inquiry and strengthening legislation are desirable in the interests of the community.

#### THE POISONS' ACT.

The extension of the poisons schedule in the sale of drugs sold either alone or in combination for the treatment or cure of disease, would help towards the security of the public. There are many potent and dangerous drugs sold to the public in the form of patent or proprietary medicines which should never be prescribed except under the advice and control of a properly qualified medical man. There is no need to go at length into the list of such drugs, but a few may be mentioned, such as acetanilide, arsenic, opium, morphia, lead, strychnine, chloral, phenacetin, mercury and its salts. What candid person would hesitate to agree to an extension of the poisons schedule when told that such a drug as colchicine is sold for the treatment of female "troubles," (a) and that one-third of a grain has been known to cause death, and as it is excreted slowly from the body, and is therefore cumulative, its administration in repeated doses in pill form is attended with serious danger? It is true that when a proprietary medicine contains a scheduled poison, the word "Poison" has to be printed on the label. The drawback to the proprietor that would be inflicted by so damaging a notice, however, is readily overcome by using type so small as to escape anything but the most careful scrutiny.

(To be continued.)

## SOME THOUGHTS ON CAUSATION IN HEALTH AND DISEASE. (b)

By LORD JUSTICE FLETCHER MOULTON.

LORD JUSTICE FLETCHER MOULTON, having distributed the prizes, began his address by saying that he knew the value of special study in any branch of science, and how presumptuous it was for those who had not trodden that toilsome path to venture to speak to those who had. But he claimed that he had been a close observer of those advances in science from the time when he first, at college, read the lectures of Lord Lister on the introduction of antiseptics into surgery. He thought he could best occupy their time if he put before them the picture which, during all those years, had gradually painted itself on his mind of the interaction between ourselves and that other world by which we are surrounded. He would aim at showing how those great scientific discoveries which would always make our age famous shaped themselves

(a) "Australian Report," 559, p. 24.

(b) Abstract of Opening Address at the School of Medicine, Leeds University, October 2nd, 1909.

to the mind of a humble looker-on, and if he might choose a distinctive title for his address he would steal the title from Robert Browning, and call it "How it strikes a contemporary."

In reviewing the 40 or 50 years that have elapsed since the birth of the new conception of the nature and causation of infective disease, Sir Fletcher Moulton roughly divided the period into two epochs, in the first of which scientific thought concerned itself mainly with the attack of these our unseen enemies, and in the second with the defence. The new knowledge, he said, early showed that it brought with it new power, and some of its most brilliant practical applications belonged to the first period. On the other hand, our knowledge of the organisms that attack us was still being added to, and much yet remained to be done in this field. The ascertainment and the comprehension of Nature's defence against micro-organisms came long subsequently to the discovery that to their action were due the numerous infective diseases to which man and animals are subject.

At some length and in great detail the lecturer considered the record of the last 40 years. Summing up that record as he had presented it, he said that science began by teaching us that we live as it were immersed in a sea of minute life, that micro-organisms are all around and upon and within us, that they are to be found not only in air and in water, but upon almost everything that we touch, that while some are harmless and possibly beneficial to us, some are our deadly enemies. It had since convinced us that all infectious diseases, as well as many that are not infectious, are due to these microbes, indeed that there are few diseases which are not either originally caused, or at some later period aggravated, by their presence. "Life," he continued, "is one ceaseless war against these enemies, and the periods of our too transient successes are known as health. This condition of constant and deadly strife not only obtains during our own short lives, but must have equally obtained throughout the long line of development of which we are the result. Yet the victory has not wholly rested with our foes. Our very existence is proof that Nature has at all events learnt how to conquer as far as she needed, that is, she has not let the individual succumb too early for the continuance of the race. We have seen how formidable her task is. She cannot effect it by isolation, for we derive our sustenance from without. The need of breath and nourishment compel free inter-communication with the external world, and we must accept its attendant microbic dangers." The choice within was equally fettered. In the life of nations, the arts of peace on which the existence of the people depended must be paramount; war was only necessary to them to assure the possibility of their continuance. Just so in the organism, the task of nourishing the cells of the body stood first; it must be performed at all costs and at all risks. Nature must defend the organism under the conditions of an uninterrupted flow everywhere of a fluid of the highest nutritious value, capable of satisfying all the wants of varied and highly specialised cells. And if nutritious to the cells, it must be liable to become food to microbes, who had to maintain their existence amid all sorts of environments unpampered by such delicate nursing.

There are, he pointed out, three main characteristics of Nature's solution of the problem. In the first place, she chooses the blood stream as the seat of the defence; nothing less than this universal environment suffices, because the mischief is equally wide. In the second place, the defence is specific; it is directed in each case against the particular assailant and no other. In the third place, it was found that in the intervals of the attacks the defence lay in capacities, not, if he might use such a term, in actualities. In other words, it is the presence of the enemy that calls into existence the changes in the blood stream that repel him, and those changes are antagonistic only to that special enemy.

Nature's task is two-fold. The microbes generate toxins which will poison the organism if not neutralised, and the microbes themselves will multiply

to a fatal extent if they be not exterminated, or at least kept down. Her defence against the first of these dangers is the generation in the blood of a specific antidote to the specific poison. Her answer to the second is manifold, but it again is in the form of the generation of defensive substances in the blood. Sometimes the defensive substances are poisonous to the specific microbe; sometimes they cripple though they do not kill. But the defence upon which she seems above all to rely is the generation in the blood stream of substances which make the watchful white blood corpuscles devour that particular microbe with a greater zest until not even its tremendous power of multiplication can save it from destruction. Asking what could be the mechanism by which it was brought about that the poison generates instead of exhausts its antidote, and that the presence of the microbe leads to the production of a suitable condiment, and thus stimulates instead of satiates the appetite to devour it, his Lordship said: "To that I can unhesitatingly give the answer—I do not know. And for myself I might put it in the yet stronger form—I have not the slightest idea. To me the mechanism that underlies these paradoxical manifestations of life is an absolute enigma." But he uttered a note of warning: "Do not confuse the facts which are learnt by experiment with the hypotheses which are designed to explain them."

#### OUTDOING NATURE.

Finally, Lord Justice Moulton called attention to the curative power that the new knowledge places in man's hand. In the cases such as diphtheria and tetanus, where the poison is so powerful and so rapidly generated that it constitutes the main danger, we can gain for Nature the time necessary for calling her defensive forces into play by introducing from without supplies of the antidote which she herself has generated abundantly under more favourable circumstances. When a specific danger threatens in the near future we can by sterile inoculations into the organism while as yet unattacked rouse into actual operation its latent capacities for defence, so that if the attack should come it will find them in full play. But, above all, in that type of microbic disease from which humanity most frequently suffers, where the micro-organisms have located themselves so as to be more or less sheltered from the operation of the blood stream, and thus to avoid rousing its powers of antagonism, we can by like means stimulate the white blood corpuscles of the whole organism to fierce attack, and, as long clinical experience has shown, can little by little drive out the enemy from the position in which it has entrenched itself.

"In all this," said the lecturer, in conclusion, "we are adopting Nature's means in order to out-do her work. For you who will in the future exercise the high calling of a doctor must never forget that you have set yourself a harder task than that with which Nature contents herself. The sacredness of human life in our eyes compels us to keep alive those that Nature would let die, to produce health where she would accept disease, to make life possible under circumstances where she would abandon the attempt. She is satisfied if the efficacy of her defence would save enough. We seek to save all. But though you thus seek to out-do Nature you cannot effect that object better than by wisely supplementing, according to individual need, that which is done automatically by Nature in racial self-defence. In so doing you will be a useful ally to Nature, and fit to fight by her side, for you will have learnt to follow her tactics."

### SOME POINTS IN THE DIAGNOSIS AND TREATMENT OF BRIGHT'S DISEASE.

By JOHN T. MACLACHLAN, M.D. GLAS.,

Assistant Physician, Glasgow Royal Infirmary.

IN practice we meet with Bright's disease, under many guises, which renders its diagnosis often one of great difficulty, and explains how it is often overlooked

The acute form of the malady is easily enough recognised; but the atrophic, chronic type is insidious and easily missed. The usual history of a case of acute Bright's disease is as follows:—The patient has had a good wetting, and in a few days, thereafter, he notices his legs are swollen, and that his urine is diminished in quantity. Some of his friends may observe that his face is swollen. He feels cold "creeps" down his back and has difficulty in getting properly warm. The physician finds marked œdema present, and that the features have lost the sharp lines of health. The lines of expression on and around the nose, under the eyes, and round the mouth are obliterated. The eyelids are saggy and puffy. Evidences of œdema may be found in the internal organs, such as moist crepitation over the base of the lungs.

The urine when boiled may go almost solid with albumen. The specific gravity is not reduced, owing to its density being more than maintained by the great amount of serum albumen it contains. Under the microscope a drop of the sediment shows numerous casts—moulds of the uriniferous tubes of the kidney, which may be studded with leucocytes, blood, and broken-up epithelial cells. The urea output may be reduced by one-half. The patient is listless and lethargic-looking, the face being pale and puffy. Usually, there is a large deposition of urates when the urine cools, and it will be observed that the urine very rapidly becomes turbid after it is passed, apparently due to organisms attacking the albumen in the urine.

The radial artery, when examined at the wrist, will be found to have lost its soft and pliable state, as in health. Its wall will be found tense, and the pulse will be short, and sharp, and jerking. All this was explained by Bright, George Johnson and others, as meaning that the arterioles contracted to resist the passage of impure blood through them. Owing to the close proximity of the supra-renal glands to the kidneys, it is unfortunate that (so far as I know) we have no definite knowledge as to their condition in Bright's disease.

The second sound of the heart is heard with undue distinctness, and is accentuated. The state of the pulse in a case of acute Bright's disease is a good guide as to the imminence of convulsions. If the pulse be exceedingly tense, convulsions may be predicted. Throbbing temporals and intense headache point in the same direction; and the urine may be reduced to a few spoonfuls, or temporarily suppressed. The pulse tension falls when the left ventricle gets dilated, but this condition is more frequently observed in advanced granular kidneys, and is one explanation how the condition is wrongly diagnosed. In the treatment of acute renal dropsy, a warm bed and a warm bedroom are of great importance. To flood the skin with blood relieves the congested kidneys. For this purpose, among others, I am in the habit of prescribing 5 minims of tincture of aconite along with 20 to 30 grains of citrate of potash every two, three or four hours, as the case may be. Aconite reduces the high arterial tension, relieves the congestion of the kidney, and a patient who is water-logged may undergo a marvellous transformation in two or three days. The urine rapidly increases in quantity, and 3 to 6 pints may be passed in the twenty-four hours. The dropsy is run out

through the kidneys—the natural channel of escape.

Milk is probably the best diet. It is not heating or stimulating, and is a good diuretic. Its diuretic quality is greatly enhanced by barley water, and half milk and half barley water is an excellent food and drink in these cases. It is not necessary to purge the patient, as is so often recommended. Nay, I consider it bad practice.

If the urinary secretion can be established, as Dickinson has so well taught, the kidneys will become unloaded, and the inflammation subside. Convulsions seem to me to occur more frequently in scarlatinal nephritis than in nephritis due to cold and wet.

I have found the application of leeches over the kidneys a very efficient mode of treating them. The milk diet may be continued for weeks, and then milk puddings, etc., added to the diet. Beef tea, I have known, cause hæmaturia in several patients, and, apparently, was toxic.

When a case of acute tubal nephritis comes under my care, I always tell the patient this is going to be a four months' job.

In looking back over my experience of acute Bright's disease I think I am safe in saying that full strength and health is not restored much under six months, and that with the patient being well charged with the astringent preparations of iron. It appears to me to be better to give a large dose of iron well diluted than frequent small doses, if it is desired to astringe the vessels of the kidneys; and this principle applies to hæmaturia as well as to albuminuria. In this way a greater quantity of the drug reaches the kidneys, and some impression is made on the condition. Thus 5 or 10 minims of tincture of iron is useless as a renal astringent.

Cirrhosis of the kidneys is such a chronic malady that it is almost impossible to say when it started.

The urine is comparatively pale, with a specific gravity of 1015 or under. If the urine be concentrated, and not more than 30 or 40 ounces be passed per day, the specific gravity may be 1020, and so be a source of fallacy in the diagnosis. Other things being equal, a persistently low specific gravity is diagnostic of atrophic kidneys. Thickened arteries with enlarged heart are corroborative of the diagnosis. Albumen may be present in small amount in the urine, and care requires to be taken in testing the urine.

When the urine is boiled, and then acetic acid added, it is absolutely necessary to boil a second time, else urine will be declared not infrequently non-albuminous, when it contains a distinct trace.

Some œdema can usually be detected in cirrhosis of the kidneys. Slight blurring of the facial lines is usually present. If the finger is vigorously pressed over the thin bone, pitting may be observed.

When the heart becomes dilated, passive congestion of the lungs and liver occurs, and gives rise to shortness of breath. The enlarged liver may be felt coming well down below the ribs, and may be tender. A tender liver in a man in comparatively good health is strong presumptive proof of alcoholism. In this way, secret drinkers among men and women may be found out.

It is not always easy to find casts in the urine from cirrhotic kidneys. The typical cast is the granular one. In dilatation of the heart hyaline

casts are the rule. They are simply due to passive congestion of the kidneys. A patient with cirrhosis of the kidneys may seek advice for headache and vertigo, for cough with bronchitis and passive congestion of the lungs; for persistent dyspepsia with gastric catarrh; for shortness of breath from cardiac failure; for insomnia and nocturnal restlessness from uræmic poisoning; for hæmaturia, presumably due to the damaged state of the vessels of the kidneys.

Nothing very certainly is known regarding the etiology of chronic Bright's disease, except as Dickinson observes, that residence in a temperate climate seems a strong predisposing cause of it.

It has not been definitely proved that alcohol causes cirrhotic kidneys, although a bout of alcohol drinking causes albuminuria and puffy face. Lead poisoning is held to be a cause of atrophic kidneys. I have known a few painters who died of cirrhotic kidneys. The question of the relation of syphilis to cirrhosis of the kidneys requires elucidation. It may be a fertile cause of the disease. Cirrhosis of the kidney is a not infrequent complication of the gouty state.

The general treatment of cirrhosis of the kidneys is as follows:—

1. The skin should be utilised as much as possible to relieve the kidneys; this may be effected by residence abroad, or by clothing, or the use of hot or Turkish baths at home.

2. Diet should be light, excluding red meat.

3. Iodide of potash with tonics seem to me to be the most reliable drug to employ, and may be persistently used for months. It reduces blood-pressure. I have known it stop attacks of Cheyne-Stokes breathing in an advanced case of cirrhosis of the kidneys.

There are many patients with stiff arteries and with renal changes, who are not typical cases of chronic Bright's disease, and belong to Gull and Sutton's group of arterio-sclerosis. Of five cases that I have classified as instances of arterio-sclerosis, occurring in working men and who have had attacks of cerebral hæmorrhage, four have kept free from a second attack of cerebral hæmorrhage, and one has had a slight relapse. They were all put on the following diet, and told to avoid strictly red meat and ham.

*Diet Allowed.*—Porridge, milk, eggs, fish, the gravy of cooked meat, vegetables, bread and butter, cheese and milk puddings and fruit. On this diet alone two cases, that were carefully watched, in three months showed great and decided improvement as regards the pulse, condition of radial artery, and feeling of well being. They afforded me strong presumptive evidence, that the way to avoid cerebral hæmorrhage lies in a lacto-vegetarian dietary. The juice or gravy of meat, while relieving the monotony of the diets did not seem to prejudice the result.

## OPERATING THEATRES.

### ST. MARK'S HOSPITAL FOR DISEASES OF THE RECTUM.

**BALL'S OPERATION FOR PRURITUS ANI.**—MR. LOCKHART MUMMERY operated on a man, æt. 29, who had been admitted suffering from severe pruritus ani, for which he had been treated for six years without any material relief. On admission, it was decided, in view of the discomfort the affection caused him, and the apparent futility of local applications, that

the wisest thing to do was to perform Ball's operation. The patient having been anæsthetised by gas and ether, was placed in the lithotomy position, and two curved incisions were made starting one on each side of the median raphe of the perinæum, and about two inches in front of the anus, their concavity being towards the anus; they were so planned as to include the anus and about an inch-and-a-half of skin all round it. The flaps formed by these incisions were then dissected up towards the anus and the dissection continued to a point a little above the muco-cutaneous junction, so as to ensure the division of all the cutaneous nerves to the itching area. The strips of skin in front and behind the anus were undercut, as also was the skin of the buttocks to the outer side of the incisions. Thus, when the dissection had been completed, the flaps enclosed by the incisions remained attached by a strip of skin in front and behind, and by the mucous membrane of the rectum. All bleeding points were next clipped and twisted, and all hæmorrhage carefully arrested by hot water and sponge pressure. The flaps were then sutured back into their original positions, and a dressing of gauze and cotton wool applied so as to keep firm pressure upon the flaps. Mr. Mummery said that the principle of the operation was similar to that often performed in cases of trigeminal neuralgia, where the fifth nerve is divided in order to stop the pain. It was not possible, he pointed out, to divide the main nerves to the anal region and skin, but this operation secures the same end by the division of the cutaneous branches. The immediate result of the operation is to render the anus and the surrounding skin anæsthetic, and therefore to entirely prevent any further pruritus; the anæsthesia passes off slowly, and within from three weeks to a month sensation has more or less completely returned in the parts. The pruritus, however, does not recur. There have been instances where the operation has not been entirely successful, but it seems probable that these cases have been due either to inadequate operation, or to selection of unsuitable subjects. The operation, he remarked, was not quite so easy as it might appear, owing to the somewhat complicated shape of the flaps. It was necessary to be very careful not to button-hole the flaps, and, needless to say, the most rigorous asepsis was indispensable, both before and after the operation. Should hæmorrhage occur under the flaps, it was desirable to remove the stitches, empty out the clot, and re-suture the flaps in place. There was no risk of the flaps sloughing, providing sepsis can be avoided and care is taken not to cut the flaps too thin. Mr. Mummery stated that he had never heard of a case in which sloughing had occurred. The operation, he thought, was obviously more scientific than the older methods of applying nitric acid or the actual cautery, and had the further advantage that, beyond leaving a small scar, it does not in any way mutilate the patient.

**CANCER OF THE SIGMOID.**—The same surgeon operated on a man, æt. 53, who had been admitted suffering from cancer in the lower half of the sigmoid flexure. The growth had been detected by means of the sigmoidoscope before admission to the hospital. The abdomen was opened in the middle line, with the patient in the Trendelenburg position, and the incision was carried down to the upper border of the pubes. The growth was found to be situated just below the middle of the sigmoid flexure and to be adherent to the loop of bowel immediately below it. Clamps were applied to the colon above and below the involved portion, and the latter was cut away. The two ends were then brought out of the wound and sutured together end-to-end, two rows of sutures being used, the inner including all the coats and the outer the peritoneal and muscular coats only. After the suturing was complete the clamps were removed and the gap in the meso-colon sewn up. A small drainage tube was inserted down to the line of suture and the abdomen closed.

Mr. Mummery remarked that a difficulty often experienced in these cases was that after resection of the growth the lower stump of colon was so deeply situated in the pelvis that anastomosis by any of the

ordinary methods was quite impossible. Under such circumstances the surgeon had three courses open to him:—(1) To establish an artificial anus with the proximal portion of the colon, and to close the lower end. (2) To excise the distal portion of the bowel and bring the upper stump down to the anus if the length of the mesentery allowed of it. (3) To tie a tube into the upper stump and pass this down through the rectum and out of the anus, and so join the two parts together by invaginating the upper stump into the lower one. He referred to a published case of his own in which this had been successfully done. He pointed out that anastomosis of the bowel, where it involved the pelvic portion of the colon, differed considerably from anastomosis in other portions of the alimentary tract, in that faecal fistulae or rupture of the line of suture more frequently occurred. This was owing to the fact that the normal contents of the pelvic colon are solid, or semi-solid, and that, in consequence, a considerable strain might be thrown on the line of suture. In order to avoid this it was necessary to ensure that the colon was thoroughly emptied previous to operation, and that the first stool after operation was entirely liquid in character. Stenosis was very uncommon after anastomosis had been performed in the colon, and need not be anticipated.

The patient in this particular case had a little discharge of clear fluid from the tube for a few days, but no faecal fistula developed, and he left the hospital in good health, and with the bowels acting normally, in a little over three weeks.

## TRANSACTIONS OF SOCIETIES.

### THE ROYAL SOCIETY OF MEDICINE.

#### THERAPEUTICAL AND PHARMACOLOGICAL SECTION.

MEETING HELD OCTOBER 5TH, 1909.

The President, PROF. A. R. CUSHING, in the Chair.

SIR CLIFFORD ALLBUTT opened a discussion on the TEACHING OF THERAPEUTICS IN THE HOSPITAL WARD.

He said medical men must be pioneers, they could not afford always to wait for the pharmacologists: but there must be a mutual watchfulness of each other. Much that we know to-day to be good came from empirical knowledge; this is still going on, but our empiricism must be of the best, the knowledge of experience. He selected three examples of methods of treatment which had stood the test of modern research, but which came originally from folk medicine, viz., digitalis; vaccination which to-day had wonderfully expanded in other directions; and poultices, which after suffering a period of abuse, were, through the work of Bier, seen to be fundamentally reasonable. The student must be assured that, apart from pharmacological proof, there was a large tradition of empirical knowledge of great provisional service. He should be told that such and such are the means found useful in clinical experience, whether they could be scientifically explained or not. They were to go to the bedside as artists to do what they could for the patient with such lights as they had. Finally, the student must be told he has to deal with living realities. He must be

(1) Assured he must be no sceptic, or he would endanger his own resourcefulness.

(2) Given a clear idea of the *vis medicatrix naturæ*.

(3) Warned against the danger of the overuse of drugs, and shown how closely therapeutics depend upon prognosis.

Professor OSLER, F.R.S., gave an account of the methods adopted at the Johns Hopkins University, laying stress on the practical advantage thereof.

Dr. HARRINGTON SAINSBURY thought there should be more careful teaching of the History of Therapeutics, and of the present day acceptance.

Dr. CALVERT said that there was a lamentable ignorance of incompatibility, and of the ordinary

simple practical methods which should all be systematically taught in the wards.

Dr. HUTCHISON relied more on teaching the student to be a sound diagnostician than a pharmacologist, and suggested that the time was ripe for some uniform agreement on the main lines of treatment to be adopted in certain well-known diseases, such as gastric ulcer.

Professor DIXON insisted on the advantage to the student of a sound pharmacological knowledge; and he pointed out the rational value of administering alkaloids when strength and action were accurately known.

Dr. BEDDARD thought it was impossible to really teach therapeutics in the wards.

Sir DYCE DUCKWORTH emphasised the necessity of imparting practical instruction to the student, such as the giving of enemata, hypodermic injections. He deplored the multitude of new so-called remedies, many coming from abroad.

Dr. HACKNEY said the student should be taught how to manage a practice, keep books, and be given a general idea of ordinary routine work.

The PRESIDENT closed the discussion with a few remarks.

### WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD FRIDAY, OCTOBER 8TH, 1909

The President, NEVILLE WOOD, M.D., M.R.C.P., in the Chair.

PRESIDENTIAL ADDRESS ON "THE SELECTION OF PATIENTS FOR SPA TREATMENT."

THE PRESIDENT (Dr. Neville Wood) prefaced his remarks by a series of propositions in which he defined the aims of spa treatment, adding a classification of the cases typically suitable for it. He then referred in turn to the therapeutic factors common to all spas, and showed how each could be used to greater advantage in an organised health resort than elsewhere. He pointed out the difficulty of the exact regulation of diet in cosmopolitan hotels, and the growing tendency to send patients to dietetic sanatoria. Passing on to the subject of radio-activity in mineral springs, evidence was cited to show that radium "emanation" possesses a selective action in some morbid conditions. Reasons were adduced for the more striking results obtained from "suggestion" at a spa than in the ordinary consulting-room. The resources of the best known watering places for the treatment of special diseases were then submitted to examination, and the paper closed by some general remarks on the relative advantages of French and German health resorts.

Paris, Oct. 17th, 1909.

#### PYELONEPHRITIS IN PREGNANCY.

PYELONEPHRITIS is not a rare affection in pregnant women, but it may pass unnoticed, for the usual classical signs are frequently wanting.

It is especially in the first period, where pyuria has not yet set in, that the diagnosis is difficult. The symptoms may be confounded, says Prof. Brindeau, with some general affection, as grippe, typhoid fever, acute tuberculosis, and it is only after several days that the possibility of pyelonephritis strikes the attendant, when renal palpation and examination of the urine confirms the suspicions.

The treatment may be medical, surgical, or obstetrical, but, in any case, medical treatment should take the precedence, and consists in the prescribing of drugs to produce diuresis and antisepsy of the digestive tract, obtained, on the one hand, by milk diet and diuretic infusions, and, on the other, by

wafers of urotropin (10 gr. three times a day) or helmitol (15 gr. twice a day). The excretion of the urine in the 24 hours should be collected and examined as to transparency and quality. Where the total amount is under the normal, wet cupping in the lumbar region may be useful.

Generally the malady gets well after delivery, and, as grave complications are the exception, a few weeks may be allowed to elapse before considering the advisability of surgical interference. Where, however, but one kidney is affected, the temperature high, the general condition bad, and a renal tumour perceptible to palpation, nephrotomy may be indicated. Before proceeding, however, to this major operation, distension of the bladder, as practised by Pasteau, may give very good results. It consists in injecting, three or four times a day, a certain quantity of liquid (10 oz. of a warm solution of boric acid) into the bladder, and recommending the patient to retain it as long as possible.

Obstetrical treatment consists in interrupting the course of gestation on the principle that the malady has a tendency to get well spontaneously after delivery, but this treatment is rarely necessary. It will depend on the age of pregnancy and the condition of the kidneys. Where pyelonephritis is observed in the first six months of gestation, it is generally grave, and as the patient is still far from her term, abortion might be thought of, but where the malady is observed in the last three months, it is better to wait Nature's time.

To resume, pyelonephritis, although a serious affection, does not generally threaten the life of the patient, and operative measures should always be reserved for grave complications.

#### PLEURISY IN CHILDREN.

The treatment of pleurisy in children may be much simplified by the employment of the wet sheet. Over a thick and warm covering is laid an impermeable cloth, on which is placed a small wet sheet previously wrung out of water at 98° to 104°. The child, undressed, is rolled in the sheet, then in the impermeable tissue, and finally in the thick covering. The treatment may be renewed daily for a week. The first day the patient is left half-an-hour thus wrapped up, the second an hour, the third an hour and a-half, and the fourth two hours, after which the time is diminished each day by half-an-hour. By this method an abundant perspiration and diuresis are produced, and in the majority of cases the effusion disappears in seven or eight days.

### GERMANY.

Berlin, Oct. 17th, 1909.

At the Naturforscherversammlung, at Salzburg, Hr. Ludvig Meyer, Berlin, gave an address on THE ACTION OF THE MINERAL SALTS IN THE DISTURBANCES OF NUTRITION OF CHILDREN.

He said that the cause of the ill-thriving of infants lay in the whey of cows' milk. The salts which the body retained from the food served for the building-up of the system, for growth. Both cardiac contractions and muscular action depended probably on certain salts in the blood. Chloride of sodium and other salts of sodium accelerated increase of weight, potassium and lime salts retarded it. The temperature of the body could be very considerably influenced by salts. Certain sodium salts raised the temperature; potassium salts reduced it. Chronic intestinal catarrhs led in infancy to great reduction of the body weight; this loss of weight was due to the loss of the salts through the abnormally copious intestinal evacuations. The loss of salts might be so great that important functions might become disturbed and life rendered impossible. But even in severe cases it was possible to prevent the destructive loss of salts by giving women's milk, and so bring about recovery. The fever also that so specially accompanied acute intestinal diseases was possibly due to imperfect digestion of mineral salts in the intestine.

Professor Elster, Wölfenbüttel, spoke of THE PRESENT POSITION OF THE RADIUM QUESTION.

He said there were three kinds of radio-active rays

that could be made evident by their photographic, fluorescent, and electric action. The latter method was of a delicacy that was far beyond that of spectrum analysis. The millionth part of a milligramme of radium was demonstrable by the test of electricity. The three kinds of radio-active rays were distinguished by the names of alpha, beta, gamma rays. The gamma rays were of greatest penetrating power; they were not influenced by the magnet, and in this they were nearly allied to the Röntgen rays, and, like these, were difficult to grasp experimentally, and were completely unexplained as regarded their nature. The alpha and beta rays were more deeply investigated; they consisted of swarms of electrically laden projectiles that were hurled out of the combination of atoms, in which the alpha rays took on a positive and the beta rays a negative electrical charge. On account of the very remarkable changes the products of the rays underwent, the study of them must lead to entirely new chemical views, and to a revolution of our views of the chemical elements.

Professor Dr. Brill, Vienna, said to the 82 known elements investigations into radio-active material had added 29 more, the study of which had been made difficult by the fact that only small traces of the material were procurable.

Geh.-Rat Professor Heubner, Berlin, addressed the meeting on the subject,

#### GRAVE DIGESTIVE INSUFFICIENCY IN THE CHILD.

He described a chronic morbid condition of the digestive organs lasting for months and years recognisable in this: that the digestive power of the child that previously benefited by its food in the usual way suddenly or gradually gave way, and the child passed into a condition of weakness, and could no longer digest even the lightest foods. This condition brought about the most extreme advancing emaciation, debility, and falling-off; it might even bring about a fatal result. The disease was not traceable to the ordinary gastro-intestinal affections. It affected well-situated children in the second and third years of life, children who were not neglected or who had no medical supervision during infancy, and who were in good condition, with normal weight, had good muscular power, were able to stand and walk, had good teeth, mostly after long-continued natural nourishment, and who sometimes had entered their second year after successful artificial feeding. It was common to all cases that cows' milk formed the principal part of the nourishment given. Under such apparently rational diet, and watched over with solicitude, the child suddenly ceased to thrive, and might remain at the same weight for months. Growth in height, also, and every other advance ceased in spite of every modification of the milk diet. The internal organs of such children showed no changes beyond a good deal of distension of the abdomen. The evacuations pointed to mischief from a milk diet. Slightly coloured, grey, and yellowish-grey, dry, firm masses of foul odour alkaline reaction often mixed with mucus, with lime soaps as the chief constituent. The condition could only be improved by leaving off the milk or reducing it to from 100 to 150 gm. a day. Cocoa, infants' prepared flour, oatmeal, biscuit, cakes, should be substituted; for dinner mid-day there should be a carefully prepared meal of meat, finely minced, vegetables and potatoes, selected with caution. In a second category of such children with weak digestions, such a change of diet will only have a favourable result for a short time, but will end in catastrophe—fever, diarrhoea, rapid fall in weight, in a few days. The danger is noticeable a few days beforehand in the character of the evacuations, which are characteristic of dyspepsia, with fermentation—copious soft evacuations, not liquid, full of gas bubbles, generally brown masses, with a sour smell and acid reaction. They show that the digestive cells are not yet capable of digesting the carbohydrate constituents of the food. In the severest cases this takes place also in regard to the sugar of mothers' milk when the attempt is made to increase the quantity of it so far as to meet the requirements of energy. There is, then, scarcely any hope of a favourable outcome. Nothing more than the albuminous constituent of the food is digested. But, with

albumen alone, nutrition is not possible. This will indeed form an important part of the day's nourishment in the shape of egg water, meat juice, caseine, carefully scraped or finely-minced roast meat; then mother's milk should be given, from which, in the speaker's opinion, the cream should be taken at first. You do more by degrees, add asses' milk where it can be done, and then, with the greatest caution, begin again tentatively with amylaceous food in the form of toasted bread. But in all these cases serious unexpected relapses and a struggle of months must be looked forward to. The essence of these rare but very remarkable affections lies, in the opinion of the speaker, in an imperfectly developed condition of the whole of the digestive apparatus, in which the functions became easily exhausted with a long-continued quantitative sameness of food.

PROF. BRAUN'S LOTION FOR SORENESS AND IRRITATION OF THE EYES.

Zinc sulph., g. iv.

Acidi borici, ʒj.

Aq. rosæ ad., ʒiv.

M. ft. Lotion.

Signe "The Lotion."

To be applied with lint with an equal part of hot water frequently during the day.

It also forms an excellent nasal spray for use during any stage of a "cold in the head."

### AUSTRIA.

Vienna, Oct. 17th, 1909.

#### CHOLECYSTITIS.

KNINA gave the history of a few cases operated on in Hochenegg's Klinik for cholecystitis resulting from influenza. According to the experiments of Mieczkowski, the gall-bladder in the human subject is always sterile, and only under pathological circumstances are micro-organisms to be found in that organ. The first and most likely infection would be the bacteria coli, typhosus, paratyphosus, and the streptococcus, but it should be more rare to meet with the staphylococcus pyogenes aureus, the diplococcus pneumoniae of Friedländer, the bacillus pyocyaneus, and the influenza bacillus; even the anaerobic gas bacillus of Laubheimer has been found in the organ.

Prior to 1903 no influenza bacilli had been proved, but in that year Heyrovsky demonstrated its presence in a female patient who had suffered from pneumonia in 1895, and who was suddenly taken ill in 1903 with fever, pain, vomiting, the pain locating itself in the region of the liver and radiating to the groin. A week later icterus increasing gradually with light coloured stools. A short interval of improvement set in, but a relapse of pain and a temperature of 40° Cent. decided the treatment in favour of an operation.

The gall-bladder was opened and 41 calculi removed, but in the course of a few days bronchitis set in, followed by pneumonia. The gall-stones were found mixed with blood and pus which contained the influenza bacilli.

Laubheimer shortly afterwards confirmed this discovery by recording two influenza cholecystites, which commenced with empyema of the gall-bladder, fever, vomiting, and pain in the right side. In the first case no previous history of an influenza attack was to be found in the clinical history. After opening the gall-bladder a bloody purulent fluid was discharged, and one calculus removed, but no offensive smell was observed.

In the second case a female who had complained of the symptoms of stone for 30 years, but two weeks before the real symptoms of cholecystitis she had influenza. Two years later she was operated on and a large stone with pus was removed, the latter containing the influenza bacilli. Both these cases appear to have been infected during an epidemic of influenza.

It is well known that icterus is very common in infectious diseases, and therefore no exception in influenza. We have, therefore, to accept the theory of swallowing the bacilli when they pass the stomach, enter the duodenum, and then pass along the ductus choledochus, and finally reach the gall-bladder. This

is the manner in which other bacilli such as the coli and typhoid reach the organ, and it is presumed the influenza passes thither by the organism being swallowed.

In Hochenegg's Klinik we have interesting cases recorded, but one briefly stated might suffice as an example. A woman, æt. 55, was received on June 28th, 1907. Fifteen years before this she suffered from vomiting after every meal. Five years before admission she observed a swelling at the margin of the ribs on the right side, with pain on pressure, vomiting, etc., till April, 1907, when she was awakened during the night with great pain over the hepatic region, but no icterus was present.

On July 3rd a pararectal cut 15 centimetres long was made at the margin of the ribs over the pear-shaped swelling, the gall-bladder opened and three stones were removed with pus. Gauze dressing and drainage was provided, but 22 days after the operation the temperature suddenly rose to 39.7 Cent., and fell as suddenly the following day.

The bacterial examination with Gram staining gave polynuclear leucocytes with a large number of non-coloured fine rods. These were partially extra-cellular and intra-cellular. No other organisms could be found, this led to the diagnosis of influenza bacilli. The agar plates were sterile, while the blood media gave large colonies of influenza bacilli. Further experiments revealed a sort of symbiosis as Heyrovsky had met with in his examinations in different media. All the anaerobic cultures were sterile.

Owing to this alternation in different media it is often difficult to diagnose the bacilli when foreign media are not at hand, but the long continuance of the discharge is a good diagnostic sign of the influenza infection. Further examination of the fluids in cholelithiasis after influenza attacks are necessary before we can determine the incidence of the disease.

#### DIABETIC THERAPY.

Noorden, in his clinical lecture on the subject, thinks systematic treatment from the very first symptom will often avert the disease or greatly modify the future progress. In the malignant form, he recognises the impotence of any form of treatment, but in the milder forms beneficial results can often be obtained by a steady perseverance in a regulated diet. As a rule, diabetes commences with transitory attacks appearing quite suddenly as a harmless alimentary or neurogenic glycosuria, rapidly terminating in progressive diabetes.

## FROM OUR SPECIAL CORRESPONDENTS AT HOME.

### EDINBURGH.

THE LATE SIR ARTHUR MITCHELL, K.C.B.—Sir Arthur Mitchell, so well-known for his pioneer work in connection with lunacy, died on October 12th, in Edinburgh. He was in his 84th year, having been born in 1826, and was the son of Mr. George Mitchell, C.E. He was educated at Aberdeen University, and afterwards studied in Paris, Berlin, and Vienna. On the passing of the Lunacy Act of 1857, he was appointed a Deputy Commissioner, and in 1870 he became a Commissioner. From his long connection with the Lunacy Board, Sir Arthur Mitchell has probably influenced lunacy administration in Scotland more than any other person, and he may be said to have been the creator of the feature of the Scottish system which is specially distinctive—the care of the insane in private dwellings, a subject on which he wrote a book in 1864. In all Sir Arthur's work he kept in view mainly the comfort and happiness of the insane, but never forgot the economic aspects of the problem. He had in an eminent degree the faculty of going to the heart of a question, and his knowledge of men and forceful, courteous personality enabled him to secure the adoption of his views even when those views were not at first welcome. His relations with all officials under him were most cordial, and his character was such that his advice and assistance were frequently sought by public and private individuals. In 1880 Sir Arthur Mitchell served on

a Commission on Criminal Lunacy, and in 1885 on a Departmental Committee on Criminal Lunatics in Ireland, and in 1889 he became a member of a Commission to inquire into the whole lunacy administration of Ireland. In recognition of the worth of his public service he received a C.B. from Mr. Gladstone in 1886, and was raised to the Order of K.C.B. by Lord Salisbury in 1887. Sir Arthur Mitchell was scarcely less famous as an antiquarian than in his own profession. For half a century he was intimately associated with the work of the Society of Antiquaries of Scotland, and during his travels as Deputy Commissioner he amassed a great quantity of notes and observations on superstitions, folk-lore, peasant customs and the like. He was the first Rhind Lecturer on Archæology, and delivered three courses of lectures, entitled "The Past in the Present: What is Civilisation?" Among academic and other honours conferred on him may be mentioned the degree of LL.D. (Aberdeen), Hon. Fellow Royal College of Physicians, Ireland, Professor of Ancient History to the Royal Scottish Academy, and H.R.S.A., Hon. Sec. Meteorological Society, Morison Lecturer in 1867-71.

**NEW LABORATORIES AT THE ROYAL BOTANICAL GARDENS, EDINBURGH.**—Owing to the increased number of students of botany in the University, it has been found necessary to plan new laboratories in connection with the class-room. The premises will contain a class-room, a water culture room, two photographic dark rooms, a dark culture room, a workshop, and a room for pathology. On the floor above there will be the mycological laboratory, the photo-micrography room, the studio, and the rooms for research work, culture, sterilisers and incubators. The plans have been prepared in, and the erection of the building is being supervised by H.M. Board of Works.

### GLASGOW.

**COMPULSORY NOTIFICATION OF PHTHISIS.**—This question was brought before the Glasgow Town Council on October 14th by a deputation consisting of representatives of 14 ward committees, 28 friendly societies, 27 trades unions, 5 co-operative societies, and the Trades Council. The spokesman of the deputation asked for compulsory notification for a term of, say, three years, the institution of district dispensaries, along with the home visitation by nurses under the supervision of an assistant doctor. They thought there should also be provision in the hospitals for advanced phthisis. The speaker hoped that the Corporation would not put the matter on a financial basis. A large amount of money was being lost to Glasgow year by year through the prevalence of this scourge, and on an actuarial basis it had been calculated that the premature deaths represented a loss of as much as a million sterling annually. At a later stage, after the deputation had withdrawn, the minutes containing recommendations by the Health Committee on the above lines were approved, so that the scheme will now be set on foot.

**SUDDEN DEATH OF DR. T. S. MEIGHAN.**—By the sudden death of Dr. Thomas Spence Meighan in a nursing home in Glasgow, on the 15th inst., the profession in Glasgow has lost one of its most distinguished surgeons. Two years ago he was appointed Senior Surgeon to the Glasgow Eye Infirmary, an institution with which he had been associated for nearly forty years. On Friday last he attended the Eye Infirmary apparently in his usual health, and was found lying unconscious in the street in the immediate neighbourhood of the hospital, from whence he was conveyed to a nursing home, and died a few hours afterwards, never having regained consciousness. We hope to give a few notes of his career in our next issue.

**THE NEW OCCUPANT OF THE CHAIR OF ANATOMY** in the University of Glasgow, Dr. Thomas Bryce, has been cordially welcomed and received both by the Senate and the students. Dr. Bryce for the last fifteen years has been seriously cultivating anatomy, chiefly at St. Margaret's College, Glasgow, where, by his researches, he has earned great distinction in the

subject of embryology. The last edition of "Quain's Anatomy" is in part the work of Dr. Bryce. His predecessor, Dr. John Cleland, has recently retired after over 30 years' service in the University.

### BELFAST.

**X-RAYS FOR COUNTY INFIRMARIES.**—A nice question has arisen in Omagh, at the Committee of Management of the County Infirmary. The Surgeon, Dr. E. C. Thompson, has applied for an X-ray outfit, and says it is absolutely essential for the interests of the institution. During a discussion on the subject, the opinion was expressed that the County Council would not give a grant for the purpose, and that the funds necessary would have to be raised by public subscription. Some subscriptions were immediately offered, and finally the matter was adjourned till next meeting, when Dr. Thompson is to present a full statement with regard to cost, etc. The question that has arisen, as to how far such an outfit is necessary in the smaller provincial hospitals, is really one of considerable importance, and an article on it by an expert would be very helpful. In most country towns it will probably be found that the chief difficulty is not to provide the outfit, but to find a man to work it. It is no doubt interesting to experiment with it as a new toy, but to work it regularly for years, when the novelty wears off, is a troublesome and monotonous task, which few men are willing to undertake. Yet unless it is properly worked by a man who takes the trouble to learn something about it, it is not only useless, but an actual source of danger.

**THE MEDICAL SESSION.**—The winter session has opened at the Belfast medical school, and the classes promise to be well filled. Entries at the University are still in progress, so it is not yet possible to give the numbers. Lectures in the medical faculty began last week, and on Thursday, 14th, the Royal Victoria Hospital started work, an address being given by Mr. Henry Hanna, Assistant Ophthalmic Surgeon.

**LADY DUFFERIN AND DISTRICT NURSING.**—The dowager Marchioness of Dufferin and Ava presided at the annual meeting of the Bangor (Co. Down) District Nursing Society last week, and gave a most interesting address on the work of the Society. She spoke with authority on the subject, as her daughter, Lady Hermione Blackwood, has acted as honorary nurse to the Society for some years. Lady Dufferin expressed the opinion that in no way could the poor be better helped than by providing nurses for them in sickness. After the address, Dr. Marion Andrews gave an interesting account of the efforts that are being made in England and abroad to promote the health of school-children. She referred at length to the importance of the district nurse as a preventer of disease, by stopping the spread of infection through ignorance. Attention was needed both in and out of school, and one of the most urgent needs of Belfast, from a health point of view, was proper school accommodation. In one school she had found infants of 3 and 4 years kept at their desks from 9.30 till 1 without a single run to freshen them, and in the half-hour interval after that they simply played in the street. Medical inspection of school-children, as introduced in England, would do untold good.

### LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

#### THE DECLINING BIRTH-RATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—This subject is of tremendous importance to the statesman, the physician, and the sociologist. I am glad you seem disposed to keep your columns open to its discussion. The subject cannot be freely and fully debated except in a medical journal. The French have pushed the idea of limitation of the family to the egoistical, logical conclusion, and every serious writer on the subject takes into account the

object lesson which they present. A correspondent last week very appropriately quoted Toynbee, and I have cited two leading Frenchmen, and could cite fifty more in support of the same views. Unfortunately the lay Press has become hypnotised by the *entente cordiale*, and criticism of our neighbours has become silenced. The *entente* had, however, its start in the fact that France recognised that without allies she would be at the mercy of Germany; whilst England and the whole of Europe, except Austria, which is bound by hoops of steel to Germany, sees clearly that they cannot allow Germany to dominate the Continent more completely and with greater force than it was dominated by the great Napoleon. Europe would be obliged to support France against Germany, if she were far more rotten than she has yet become. I said in a previous letter that the signs of the moral decay of the French were unquestionable. It is interesting to read in *The Times* a report of Dr. A. Shadwell's speech on this subject at the Church Congress on Wednesday. If you will allow me now to summarise this speech I may return to the subject in future letters. Many points call for discussion, among them the question of the effects upon the organs of generation and the nervous system of women, who systematically prevent conception by artificial means, needs examination. Dr. Shadwell spoke to the following effect:—"He had recently spent some months studying conditions all over France. The country was saturated with the Materialism and moral irresponsibility taught by Socialism, and one result was a veritable anti-Christian persecution. Did they know that in France to-day public officials with anything to lose dared not be seen going to church with their wives and children? Sometimes even their wives dared not go. They were spied on and reported. The jurors in the Department of the Yonne had recently petitioned the Government to have the word 'God' removed from the oath on the ground that it offended their conscience, because they did not believe in the existence of God. The worship of Mammon was supreme. There was no respect for anything whatever but the appearance of wealth. He had made that observation to many Frenchmen and Englishmen long resident in France, and they all admitted its truth. We had not got so far, but we were on the road." The bulk of the French have cast aside religion, and have found nothing to put in its place. They have adopted the view of their cynical writer, who asked: What has posterity done for us? Their motto is: Let us eat and drink for to-morrow we die; and they are making this idea a concrete fact from the national point of view by the adoption of the pernicious practice, which the British race now unfortunately seems determined to imitate.

I am, Sir, yours truly,

A STUDENT OF SOCIOLOGY.

October 9th, 1909.

## OBITUARY.

SIR ARTHUR MITCHELL, K.C.B., LL.D., UNIV. EDIN.

We regret to announce the death of Sir Arthur Mitchell, at his residence in Edinburgh, at the age of 83. The son of Mr. George Mitchell, C.E., he was born in 1826, and received his early education at Elgin, and afterwards at Aberdeen University, whence he proceeded to Paris, Berlin and Vienna. At the passage of the Lunacy Act of 1857 he was appointed Deputy Commissioner, and in 1870 he was made a Commissioner. From 1867 to 1871 he was Morison Lecturer on Mental Diseases to the Royal College of Physicians of Edinburgh, and he was a member of the Commission on Criminal Lunacy in 1880-81, and Chairman of the Commission on Lunacy Administration from 1888 to 1891. During this long period he was engaged in many legal cases involving questions of insanity, and by his character and intellectual force he did more than any other man towards shaping the lunacy administration of Scotland in its present form. Sir Arthur was a man of wide acquirements outside

medicine. He was a prominent member of the Society of Antiquaries of Scotland, and Rhind Lecturer in Archæology from 1876 to 1878, founded on which was his well-known work, "The Past and the Present: What is Civilisation?" In 1901 he wrote a valuable history of the preceding fifty years' work of the Society. He was also Professor of Ancient History to the Royal Scottish Academy from 1878, a member of the Universities (Scotland) Commission, which sat from 1890 to 1897, and President of the Scottish Meteorological Society. The University of Edinburgh conferred on him the honorary degree of LL.D. in 1884, and three years later he was created K.C.B.

From the above short and imperfect record it will be seen that Sir Arthur Mitchell's life was one of extraordinary activity and breadth of intellectual outlook. A keen observer of men and things, he brought to bear on all matters he undertook the energies of a powerful and highly-trained mind.

Sir Arthur Mitchell's wife, a daughter of the late Mr. James Houston, of Strathspey, died a few years ago. He leaves one son, Mr. Sydney Mitchell, the architect. One of his nephews is Dr. George Ogilvie.

## SPECIAL ARTICLES.

### LUNACY IN IRELAND.

THE Annual Report of the Inspectors of Lunatics in Ireland (a) shows that the total number of lunatics under care on the 1st January, 1908, was 23,931, a number which showed an increase during the year of 213. The increase for the previous year was 164. The average increase for the preceding ten years was, however, much greater—413. We are glad to note that the number of insane in workhouses continues to show a steady decrease.

The proportion of insane under care to the total population has increased even more than the actual numbers of insane, as the population has for many years, until the present, shown a steady decline. The proportion has more than doubled in thirty years. In 1880 there were 250 insane under care in every 100,000 of the population, whereas at present there are 547 in every 100,000. The rate of increase for the past three years has been 5 per annum, whereas the average rate during the entire period was over 10 per annum.

The admissions during the year amounted to 3,798; the discharges were 1,848, the escapes 6, and the deaths 1,417. Of the 1,848 discharged 1,401 were regarded as having recovered. In only 235 cases was the cause of death verified by autopsy. Of the 1,417 deaths 372, or 26.3 per cent., were due to phthisis. The highest rates for phthisis were: in Clonmel (50), Killarney (41.2), Ballinasloe (35.1), Ennis (34.4), and Cork (34). The conditions in some of these asylums seem to call for careful inquiry. The lowest rates were in Carlow (3.1), Armagh (9.7), Letterkenny (10.5), and Waterford (12.5). The means by which such excellent results have been obtained might well be applied elsewhere.

In the year 1908 there were 4 deaths by misadventure, 5 by suicide, and 1 from injuries inflicted by a fellow-patient. One of the cases of suicide was curious. In Ennis Asylum a patient was put to sleep in a padded room under the restraint of a strait jacket. He succeeded in removing the restraint jacket, and flattening with his teeth the round metal tag of the lace which fastened it, he used the tag for making an incision in his abdomen by cutting the skin and subcutaneous tissue, afterwards enlarging the wound thus made with his fingers, and in this way reached the intestines, and tore out some coils, 16 feet in length, severing them completely from the body.

There were several outbreaks of typhoid fever in district asylums during the year. In Ballinasloe Asylum seventeen cases occurred, in Ennis seven, and in Mullingar seven. Forty-nine cases of dysentery occurred in the Richmond and Portrane Asylums.

(a) "Lunacy in Ireland." The Fifty-eighth Annual Report (with appendices) of the Inspectors of Lunatics (Ireland) for the year ending December 31st, 1908. Dublin: H.M. Stationery Office. 1909. (Bd. 4,760.) Price 11d.

Waterford Asylum had the honour of showing the lowest death-rate—4.1 per cent. of the average number resident.

As regards expenditure, the highest net average cost per patient was in Sligo, £26 17s. 11d., and the lowest in Castlebar, £18 4s.

The Inspectors note with pleasure the tendency to increase the amount of land attached to the various asylums, and they urge the importance of engaging patients in farm and other work. "Not only," they remark, "do large farms attached to asylums afford means of healthy labour in the open air, and an outlet for that restlessness and desire of motion so common amongst the insane, thus producing quietude and peace where formerly there was noise and excitement, but the interest aroused in agricultural work also brings back the wandering mind to sane views, and so helps to promote recovery. Moreover, large tracts of land attached to asylums enable the patients, both male and female, to take extended and varied walks, and to enjoy the open air without encroaching on the public thoroughfares—a course which often gives rise to complaints by the sane community."

As evidence of the humanity shown by the asylum staffs generally, it is satisfactory to find that in only two cases were prosecutions of attendants deemed necessary during the year.

## MILITARY & NAVAL MEDICAL NOTES.

**HEALTH IN THE FRENCH ARMY.**—The sickness in the French Army has, according to statistics, been greater lately, and has been put down by the military authorities to the fact that men in indifferent health at the time of enlistment were put to active work, rather than that insanitary conditions were factors in the causation of increased ill-health. But, before giving our opinion as to the share each or both have, we should require to read the sanitary report. The average of 269 per 1,000 sick is very high, and it merely accounts for men admitted into military hospitals. Sick treated in quarters are not included. These would bring up the numbers to 134,631, and their time under treatment is given as 3,101,126 days. Algeria and Tunis gave 25,126 hospital admissions, or a proportion of 360 per 1,000 of strength higher than in previous years. Their treatment totalled 648,601 days.

**THE PHYSIQUE OF THE GERMAN AND BRITISH SOLDIER.**—A writer to a military weekly, commenting on the recent German manoeuvres, says, of the physique of the German soldier of two years' service and that of the British soldier of similar service on the peace establishment, that "the odds are rather in favour of the German at present."

## REVIEWS OF BOOKS.

### PRACTICAL MICROSCOPY: AN INTRODUCTION TO MICROSCOPICAL METHODS. (a)

COMPARATIVELY few medical men know anything much about the microscope. They understand how to illuminate the object and how to use the coarse and fine adjustments, and here their knowledge ends. To those who wish to get the best work out of their instrument we heartily commend this book. It will also be of very great assistance to those who propose to buy a microscope, as the author gives his experience of the various makes of stands and objectives. Dr. Shillington Scales is so well-known as a famous microscopist that it is superfluous to point out his qualifications for dealing with the subject. In the present edition such subjects as photography with ultra-violet light and apparatus for examining ultra-microscopic

particles are fully dealt with. Microscopical technique and section cutting are so dealt with that the comparatively inexperienced worker for whom the book is mainly written will be assisted as much as possible. The considerable enlargement of the book and its extended scope we think fully warrant the change in title from "Elementary Microscopy."

### OPERATIONS ON THE EAR. (a)

ESSENTIALLY a German work, based upon the author's experience in Luede's clinic, this book describes and recommends those operations concerned with middle-ear suppuration which are practised there. Naturally, therefore, all the authorities quoted are German, with the sole exceptions of Wilde and McEwen. The translation has been excellently done by Dr. Murphy, and to English practitioners who worship German surgery and are inclined to depreciate the good work done in their own country, this work will prove an attraction.

As regards paracentesis of the drum, the opinions of Zaufal and Piffi that middle-ear inflammations run a cyclic course, and that consequently paracentesis should be avoided, are rightly objected to by Heine. Two matters surprise us: that a horizontal incision is advocated, and the use of a mirror held by the teeth advised. Nor can we agree that the snare which Heine prefers for the removal of aural polypi is nowadays "universally employed."

We were especially interested in the author's remarks regarding ossiculectomy, an operation in the value of which he states that he has of late years lost faith. Our own opinion upon the matter is that indiscriminate removal of ossicles is to be deprecated, but that, in picked cases, and combined with ablation of the outer attic wall, it is often of considerable value.

Mastoid operations are dealt with in Chapters II., III., and IV., but we would point out that the great superiority of the gouge over the mallet and chisel, which is owed entirely to English otology, is passed over in absolute silence. The discussion on p. 86, too, might have been obviated by reference to the work of another English surgeon, Jones, of Liverpool. We fully approve of Heine's disagreement with the grafting operation, and it is interesting to note that the work of Ballance (entirely German in its origin) in connection with this method is wholly ignored, a fate which, less merited, is also meted out to British work on labyrinthine suppuration.

Part II., devoted to intra-cranial complications, is adequate, and calls for no special mention.

### DIATHESIS AND OCULAR DISEASES. (b)

THIS volume comprises, the author tells us, his post-graduate lectures delivered at the Glasgow Ophthalmic Institution in September, 1908. As a record of personal clinical experience these lectures are both interesting and useful, and especially so on account of the wide range of subjects which they include. After discussing the various diatheses, such as the neurotic, the rheumatic, and gouty, the author passes in review the ocular inflammations, which mainly apply to these conditions. Thus we have chapters upon inflammation of the conjunctiva and of the sclerotic, of the uveal tract, of the retina and optic nerve; also toxic amblyopia and retro-ocular neuritis, concluding with an excellent chapter upon glaucoma. Many details of treatment are given in the description of these various diseases, based upon the author's own experience; indeed, the practical, useful advice with which the volume abounds renders it well worthy of perusal by practitioners, to whom its pages especially appeal. The text, moreover, is illustrated by seventeen plates, representing various forms of ocular disease. The volume is of handy size, and we can cordially recommend it.

(a) "Operations on the Ear: The Operations for Suppurative Otitis Media and its Intracranial Complications." By B. Heine. Translated by W. L. Murphy, M.A., M.B. Cantab., B.O., F.R.C.S.I., Surgeon to the Throat and Nose Department, St. Vincent's Hospital. Pp. 218, with 56 illustrations. London: Baillière, Tindall and Cox. 1909. Price 5s. 6d.

(b) "Diathesis and Ocular Diseases." By A. Maitland Ramsay, M.D. Lond. Pp. 192, with 17 plates. London: Baillière, Tindall and Cox, 1909. Price 3s. 6d.

(a) "Practical Microscopy: An Introduction to Microscopical Methods." By F. Shillington Scales, M.A., B.C. Cantab., Fellow of, and Curator to, the Royal Microscopical Society; Hon. Medical Officer in charge of Electrical Department at Addenbroke's Hospital, Cambridge. Second Edition. Pp. 334 and xvi, with 122 illustrations. London: Baillière, Tindall and Cox. 1909.

## NEW BOOKS AND NEW EDITIONS.

THE following have been received for review since the publication of our last monthly list:—

EDWARD ARNOLD (London).

A System of Clinical Medicine. By Thomas Dixon Savill, M.D.Lond. Second edition, revised by the Author, assisted by Frederick S. Langmead, M.D.Lond., and Agnes F. Savill, M.A., M.D. Illustrated. Pp. 963. Price 25s. net.  
Elementary Physiology for Teachers and Others. By W. B. Drummond, M.B., C.M., F.R.C.P.Edin. Illustrated. Pp. 198. Price 2s. 6d.

HAILLIERE, TINDALL AND COX (London).

The Open-Air or Sanatorium Treatment of Pulmonary Tuberculosis. By F. Rufenacht Walters, M.D., B.S.Lond., M.R.C.P., F.R.C.S. Pp. 323. Price 5s. net.

Practical Microscopy. An Introduction to Microscopical Methods. By F. Shillington Scates, M.A., B.C.Cantab. Second Edition. Illustrated. Pp. 334. Price 5s. net.

The Morphia Habit and its Voluntary Renunciation. By Oscar Jennings, M.D., Paris. Pp. 492. Price 7s. 6d. net.

Age Incidence, Sex, and Comparative Frequency in Disease. By James Grant Andrew, M.B., B.Ch., F.F.P. and S.Glasg. Pp. 439. Price 10s. 6d. net.

JOHN BALE, SONS, AND DANIELSSON, LTD. (London).

Jejunal and Gastro-jejunal Ulcer, following Gastro-jejunostomy. By Herbert J. Paterson, M.A., M.B., etc. Pp. 72.

CASSELL AND CO., LTD. (London).

Diseases of the Stomach. By S. H. Habershon, M.A., M.D., F.R.C.P. Illustrated. Pp. 565. Price 9s. net.

J. AND A. CHURCHILL (London).

Sight Testing Made Easy. By W. Wright Hardwicke, M.D., M.R.C.P. Pp. 66. Price 2s. 6d. net.

ARCHBOLD CONSTABLE AND CO., LTD. (London).

Studies in Tuberculosis. By Henry Clarke, M.A., M.D.Cantab. Pp. 59. Price 5s. net.

CORNISH BROS., LTD. (Birmingham).

Contributions to the Study of Rectal Diseases. By Victor Milward, B.A., M.B., etc. Pp. 92. Price 2s. net.

FROWDE, HENRY, AND HODDER AND STOUGHTON (London).

Text-book of Anatomy. Edited by D. J. Cunningham, F.R.S., M.D.Edin. et Dubl., D.Sc., LL.D.Glasg. et St. And., D.C.L.Oxon. Third Edition. Pp. 1,427. Price 31s. 6d. net.

A System of Operative Surgery. By various Authors. Edited by F. F. Burghard, M.S.Lond., F.R.C.S.Eng. In four volumes. Vol. II. Pp. 720. Price 36s. net.

Infectious Diseases. A Practical Text-Book. By Claude Buchanan Ker, M.D.Ed., F.R.C.P.Ed. Pp. 555. Price 20s. net.

Introduction to Practical Chemistry for Medical, Dental, and General Students. By A. M. Kellas, B.Sc.Lond., Ph.D. Heldb. Pp. 262. Price 3s. 6d. net.

Gall-Stones: Their Complications and Treatment. By A. W. Mayo Robson, D.Sc., F.R.C.S., and F. J. Cammidge, M.D. Pp. 315. Price 5s. net.

GALE AND POLDEN, LIMITED (London and Portsmouth).

Gale and Polden's Military Series. Guide to Promotion for Non-Commissioned Officers (Corporal to Staff Sergeant) and Men of the Royal Army Medical Corps. With Appendix on Hints for Young N.C.O.'s on Clerical and Other Duties in a Military Hospital. Compiled by Captain S. T. Beggs, M.B., Royal Army Medical Corps (Reserve of Officers). Second Edition. Price 3s. 6d. net.

H. K. LEWIS (London).

The Theory and Practice of Medicine. By Frederick T. Roberts, M.D., B.Sc., F.R.C.P. Tenth Edition, with Appendix, 1909. Pp. 1,410. Price 12s. 6d. net.

Medical Morbid Anatomy and Pathology. By Hugh Thursfield, M.D., F.R.C.P., and William P. S. Branson, M.D., M.R.C.P. Pp. 262. Price 6s. net.

LONGMANS, GREEN AND CO. (London).

Outlines of Bacteriology (Technical and Agricultural). By David Ellis, Ph.D., D.Sc., F.R.S.E. Pp. 263. Price 7s. 6d. net.  
The Vegetable Proteins. By Thos. B. Osborne, Ph.D. Price 3s. 6d. net.

Anatomy: Descriptive and Applied. By Henry Gray, F.R.S. 17th Edition, revised and edited by Robert Howden, M.B., C.M., Professor of Anatomy in the University of Durham. With 1,032 illustrations. Price 32s. net.

Recent Advances in Physical and Inorganic Chemistry. By A. W. Stewart, D.Sc., with an Introduction by Sir William Ramsay, K.C.B., F.R.S. Pp. 267. Price 7s. 6d. net.

Quain's Elements of Anatomy. Edited by E. A. Schäfer, LL.D., Sc.D., F.R.S., J. Symington, M.D., F.R.S., and T. H. Bryce, M.A., M.D. In four volumes. Vol. III, "Neurology," by E. A. Schäfer and J. Symington. Part II. Eleventh Edition. Illustrated. Pp. 384. Price 15s. net.

The Family and the Nation. By William Cecil Lampier Whetham, M.A., F.R.S., and Catherine Dunning Whetham, his Wife. Pp. 233. Price 7s. 6d. net.

E. AND S. LIVINGSTONE (Edinburgh).

Deuteronomy Smith. New Edition. Illustrated. Pp. 68. Price 1s. net.

Arsenic Gas Poisoning. By John Glalisher, M.D., D.P.H. Price 5s. net.

Chemistry. Part II. Inorganic and Organic. Pp. 73. Price 1s. net.

MACMILLAN AND CO., LTD. (London).

A System of Medicine. By Many Writers. Edited by Sir Clifford Allbutt, K.C.B., etc., etc., and Humphry Davy Rolleston, M.A., M.D., etc. Vol. VI. Diseases of the Heart and Blood-Vessels. Pp. 861. Price 25s. net.

G. STEINHEIL (Paris).

Leucopathies Metastases. Par Le Dr. Emile Feuille. Pp. 195.

JOHN WRIGHT AND SONS, LTD. (Bristol).

Dictionary of Ophthalmic Terms, with Supplement. By Edward Magennis, M.D., D.P.H. Pp. 67. Price 2s. 6d. net.

## LABORATORY NOTES.

## "AKOLL" BISCUITS.

THE repugnance often evinced by patients to foods free from carbohydrates is well-known to every practitioner, who finds considerable difficulty in selecting nutriment that will appeal to the palate without impeding his treatment. To such we would strongly recommend a trial of these "Akoll" biscuits. The name is very appropriate, as we find them to contain only a very slight trace of starch, and we have not found any sugar to be present.

Our analysis shows the biscuits to contain:—

Moisture	...	...	4.24 per cent.
Proteins	...	...	57.17 "
Mineral matter	...	...	3.98 "

Most of the remaining constituents are fats, so that these biscuits can be termed "highly nutritious" with all truthfulness. No less than seven different proteins are said to be embodied in these biscuits, and they are recommended not only for cases where starch and sugar must be avoided, but also for invalids and for aggravated cases of corpulency.

The palatability of such preparations is largely a matter of opinion, but we think that most patients would eat "Akoll" biscuits with satisfaction.

## MEDICAL NEWS IN BRIEF.

## Royal College of Surgeons of Ireland.

THE Winter Session opened on Friday last with an address by the President, Mr. Lentaigne, when the following medals and prizes were distributed:—Barker Anatomical Prize—£26 5s., H. R. Tighe; special prize, £21, J. S. Pegum. Carmichael Scholarship—£15, J. T. Duncan. Gold Medal in Operative Surgery—Miss I. M. Clarke; silver medal, F. N. Harvey. Stoney Memorial Gold Medal in Anatomy—J. T. Duncan. Various minor prizes in Anatomy, Medicine, Surgery, Midwifery, Physiology, Pathology, and Chemistry were also distributed, there being about 200 students present at the ceremony.

## St. Vincent's Hospital, Dublin.

AT the annual meeting at St. Vincent's Hospital, introductory to the work of the Winter Session, Dr. Andrew Horne, President of the Royal College of Physicians, occupied the Chair.

Mr. P. J. Fagan, Surgeon to the Hospital, delivered the inaugural address. He began by declaring open the new operating theatre which has been built in the hospital, and which is a good example of such buildings. After some references to ancient and modern methods of teaching the student, and to the teaching of the modern nurse, Mr. Fagan went on to refer to the anti-tuberculosis movement in Ireland, a movement which he considered as too prone to advertise the faults rather than the good points of the country. A vote of thanks was moved to the lecturer for his address by the Most Rev. Dr. Donnelly, seconded by Dr. Cox, the latter of whom expressed disagreement with his views on the tuberculosis question. Finally a vote of thanks was proposed to the Chairman by Dr. McWeeney. The audience then inspected the new theatre, and the meeting terminated.

## Cardiff Medical School.

THE Treasury has allocated £1,500 a year to the Cardiff School of Medicine. In spite of Sir Donald MacAlister's note upon the Faculty of Medicine in the University College, Cardiff, published in the recent report of the committee on the University of Wales and the Welsh University Colleges, few imagined that the committee would second his praise in such a practical manner. The Cardiff Medical School was started less than twenty years ago, chiefly through the enterprise and energy of Dr. Edwards, of Cardiff.

By founding two chairs, one of anatomy and the other of physiology, and by the foundation of a lectureship of *matra medica*, all of which were attached to the Cardiff and Monmouthshire University College, in which institution chemistry, physics, botany and zoology were already taught, students of medicine were enabled to spend at least three out of their five years at Cardiff. The University of Wales has appointed a medical board whose chief work has been the drawing up of regulations for the Welsh M.B., B.Ch., under the able guidance of Sir Isambard Owen. The Cardiff Infirmary has been advancing by leaps and bounds. It has an excellent staff of surgeons and physicians, and is in most respects up to date; and in two years' time, when its new wing is built, it will be fitted to accommodate students who wish to spend all their five years of study in Cardiff. Cardiff possesses also a fever hospital, and an asylum within a tram drive of the infirmary.

#### Leeds Medical School.

THE following is a list of the prizes presented on October 2nd, 1909:—

Anatomy, Junior.—G. P. Mellis, prize; J. C. Metcalfe, certificate. Anatomy, Senior.—W. Robinson, prize; F. Wigglesworth, certificate. Physiology.—G. P. Mellis, prize; J. C. Metcalfe, certificate. Physiology, Practical.—W. Robinson, prize; J. B. Sinson, certificate. *Materia Medica*.—J. C. Metcalfe, prize; G. P. Mellis, certificate. Silver Medal.—W. Robinson, prize. Pathology.—H. S. Raper, prize; J. B. Fisher, certificate. Mental Diseases.—J. N. L. Thoseby, certificate. Pharmacology.—W. H. Hooton, prize; J. P. Brown, certificate. Ophthalmology.—G. H. Cross, prize. Gynaecology.—J. N. L. Thoseby, prize; G. H. Cross, certificate. Obstetrics (Scattergood Prize).—I. B. Bernstein, prize; H. V. Lamb, certificate. Public Health (Thorp Prize).—G. H. Cross, prize; J. B. Fisher, certificate. Forensic Medicine (Thorp Prize).—G. H. Cross, prize; J. B. Fisher, certificate. Medicine.—J. N. L. Thoseby, prize. Surgery.—No award. Surgery, Practical.—B. A. Slocombe, prize. Clinical Medicine (Hardwick Prize).—J. N. L. Thoseby, prize. Clinical Surgery (McGill Prize).—J. N. L. Thoseby, prize.

Gold Medal (presented by the Faculty of the General Infirmary at Leeds).—J. N. L. Thoseby.

#### Health of the City of London.

DR. COLLINGRIDGE, medical officer of health for the City, reports that during the quarter ended September 30th the City death-rate was 9.3, as against 11.4 in the rest of the metropolis, and the birth-rate 13.3, as compared with 24. Eleven cases of infectious disease were reported, and six notifications of pulmonary tuberculosis received. In the recess 1,601 houses were inspected and 30 notices served to abate nuisances. At riverside wharves 44 tons of unsound food were condemned. At the markets and slaughter-houses 345 tons of meat were seized, of which 84 tons were frozen meat. Out of 218 samples of food and drugs analysed, two of milk and one of saffron were found to be sophisticated. Of a total consignment of 4,663 carcasses of frozen Chinese pork received in July, 884 were thawed and examined, and 80 of these condemned as unfit for human food. At the mortuary 76,345 articles of second-hand clothing were disinfected prior to being exported to South Africa. Fifty-four bodies were received at the mortuary and 48 inquests held.

#### The Port of London and Infectious Diseases.

THE September returns give 789 ships as arrived in the Port of London from foreign seaports. Of these, more than half were British. In all 1,285 inspections of these vessels took place. In the same month 1,822 inspections of coastwise and inland navigation vessels were made by the medical staff. Seventeen cases of infectious disease were reported. The medical officer states that there has been a small outbreak of scarlet-fever and mumps on the training-ship *Warspite*. The former cases have been dealt with at the Marine Society's Hospital at Denton, and the others at the

isolation hospital on shore belonging to the *Warspite*. One case of anthrax has been reported, the patient being a sailor on board a vessel in which dried hides were being carried. Nine alien immigrant ships arrived during the month, bringing 235 alien steerage passengers. They were all medically inspected and admitted.

#### The Housing Bill.

THE Medical Officers of Health in the smaller districts are not given security of tenure. They are still left with their short periods of appointment, often from year to year only, knowing that any exhibition of zeal in the condemnation of insanitary property is as much as their places are worth. And, as if in irony, the County Medical Officers, whose duties bring them much less into contact with areas of small house property under the conditions that exist in district areas, are given the needed security—that is to say, they cannot be got rid of without the sanction of the Local Government Board. In the smaller areas private interests continually confront the sanitary officer in the execution of his work, and he, above all, should be secured from arbitrary dismissal for the conscientious discharge of his duty. Apparently it is too much to expect the House of Lords to give the security. Far from having made any attempt to render the position of the Medical Officer of Health in the smaller areas more secure, the House has actually gone out of its way to remove the security of tenure even of the County Medical Officers, which at any rate was secured by the Bill as it left the Commons.

#### Chinese Pork.

MR. BURNS: Inquiries were made by the Local Government Board some months ago, before this consignment arrived, as to the character of the pork, as to the method of feeding the pigs, and we were quite satisfied that they were perfectly satisfactory. I can only say, in answer to these further questions, that it has been said on the authority of the *Meat Trades Journal* that the pork is excellent of its kind, that this was proved by the prices realised, that it was sound and wholesome, and had passed the double inspection of the Port sanitary authority and the eagle eye of the practical meat inspectors of the Local Government Board.

#### Child's Death Under an Anæsthetic.

THE death of a boy, aged 12 years, was investigated by the Portsmouth Borough Coroner on the 6th inst.

The mother stated that her son had suffered lately from an obstruction in the nose, and she had been recommended to send him to the Portsmouth Eye and Ear Infirmary. He was sent there on the 27th ult., but died on October 4th.

Dr. A. Scott Ridout said that he first saw the child in July last, and he then came to the conclusion that an operation was necessary for nasal obstruction and adenoid growths. Dr. Paul Green, the official anæsthetist, administered, first chloroform and later a mixture of chloroform and ether. When under the anæsthetic, witness injected a small dose of adrenalin, with the object of restricting the flow of blood from the nasal vessels. This was what he usually did in such cases, and he had administered it with success in at least thirty cases. The child behaved very well under the anæsthetic, but after the injection of the adrenalin witness noticed a strange pallor of the face. This was very unusual, and witness immediately opened the mouth, pulled the tongue forward, and commenced artificial respiration. After a minute or two the child began to breathe again quite naturally, but continued to do so for only a short while. Witness continued with the artificial respiration for about thirty minutes, and, as a last resource, tracheotomy was performed, but without success.

Dr. P. Green corroborated Dr. Ridout's evidence. The patient showed no danger sign after the administration of the anæsthetic. When the needle used for the administration of the adrenalin was first injected, the child gave a slight movement.

Dr. Lysander Maybury gave evidence of the post-mortem examination. He said that the nose passage

was almost entirely obstructed. He considered that the introduction of the needle beneath the mucous membrane of the nose caused reflex action. That, with the reflex action caused by an attempt to vomit, not produced by the introduction of the needle, acted in a reflex manner upon the heart, causing inhibition or stoppage, and so producing fatal syncope. Witness did not think that the drug had anything to do with death. It was simply the insertion of the needle. He had used the drug himself, because it produced a bloodless field for operation, which was very important in the case of the nose and throat.

The jury returned a verdict of "Death from misadventure," and added that they thought every care had been taken.

#### The Murder of Dr. Lalcaca.

MR. M. M. GANDEVIA, Hon. Secretary of the Edinburgh Parsi Union, asks us to publish the following letter received by him from Lord Knollys on behalf of His Majesty the King:—

Copy of the letter from Lord Knollys, Private Secretary to the King, conveying His Majesty's gracious acceptance of the "In Memoriam" to Dr. Cowas Lalcaca, published by the Edinburgh Parsi Union.

"Balmoral Castle.

"Lord Knollys has had the honour of submitting to the King the copy of the 'In Memoriam' to Dr. Cowas Lalcaca, which accompanied Mr. Gandevia's letter of the 15th ult., and, in reply, is commanded to inform Mr. Gandevia that His Majesty has much pleasure in accepting it.

"Lord Knollys regrets that, owing to a slight accident, he has been unable to answer the letter before.

"October 9th, 1909."

#### Catholic University Medical School Past and Present Students (Conjoint).

At a meeting of the above students held in the Gresham Hotel, Saturday, the 9th, Dr. Adye-Curran presiding, the following resolution was proposed and passed unanimously:—"We, the past and present students of the Catholic University Medical School, with non-University 'qualifications,' respectfully approach the Governing Body of the National University and request that they will be good enough to consider the position occupied by us at present, and kindly say what concessions they would feel disposed to grant in the event of our seeking a medical or dental degree."

All those interested in the question are cordially invited to communicate with the Secretary, "Conjoint Cecilians," Apothecaries' Hall, Dublin.

### PASS LISTS

#### The Royal University of Ireland.

THE following candidates have passed the under-mentioned examinations:—

The M.B., B.Ch., B.A.O. Degrees Examination.—Upper Pass.—James A. Brown, James B. Butler, M.A., John J. Gilmore, James A. Hanrahan, Edward G. Kennedy, Ernest W. Kirwan, John M. McCloy, Thomas Scanlon.

Pass.—Charles Alexander, Joseph Anderson, John A. Black, Percy M. J. Brett, Bartly Byrne, Samuel R. Campbell, Francis S. Carson, David S. Clarke, B.A., Albert V. Craig, William Dickey, William A. Frost, Patrick Hayes, Jeremiah Holland, David Horgan, John C. Houston, David J. Jackson, B.A., Thomas Kennedy, Henry H. MacWilliam, B.A., William Magner, Thomas P. Magnier, Thomas J. S. Moffett, Alexander Patton, B.A., Samuel P. Rea, Jeremiah Reidy, David A. Rice, Alfred M. Thomson.

Exempt from further Examination in Medicine and Midwifery.—John H. Harbison, B.A., Queen's College, Belfast.

The following candidates may present themselves for the further examination for Honours in the groups set opposite their names:—

James B. Butler, M.A., Medicine, Midwifery; Bartly Byrne, Midwifery; Samuel R. Campbell, Midwifery; William Dickey, Surgery; John I. Gilmore, Medicine; James A. Hanrahan, Midwifery; Edward G. Kennedy, Medicine, Surgery; Ernest W. Kirwan, Midwifery, Surgery; John M. McCloy, Medicine; Jeremiah Reidy, Medicine; Thomas Scanlan, Surgery.

The M.D. Degree Examination.—John Finnegan, M.B., B.Ch., B.A.O.; Samuel J. Killen, M.B., B.Ch., B.A.O.; Charles B. Pearson, M.B., B.Ch., B.A.O.; Stephen B. Walsh, B.A., D.P.H., M.B., B.Ch., B.A.O.; Thomas Walsh, B.A., D.P.H., M.B., B.Ch., B.A.O.; Samuel H. Whyte, M.B., B.Ch., B.A.O.; James E. Wilson, M.B., B.Ch., B.A.O.

The Diploma in Mental Diseases Examination.—The following candidate has passed the examination:—Daniel Gillespie, M.D.

#### Royal Academy of Medicine in Ireland.

At the annual general meeting of the Royal Academy of Medicine in Ireland, held on Friday, October 8th, the following officers were elected for the session 1909-1910:—

President—Sir Charles B. Ball.

General Secretary—James Craig.

Secretary for Foreign Correspondence—Sir John Moore.

Medical Section—President, Walter G. Smith. Council—W. R. Dawson, H. C. Drury, J. A. Matson, T. G. Moorhead, J. F. O'Carroll, A. R. Parsons, G. Peacocke, F. C. Purser, E. J. Watson, W. A. Winter.

Surgical Section—President, John Lentaigne, P.R.C.S. Council—C. A. Ball, Alex. Blaney, Sir A. Chance, L. G. Gunn, W. S. Haughton, Seton Pringle, Henry Stokes, E. H. Taylor, W. Taylor, W. I. de C. Wheeler.

Obstetrical Section—President, H. Jellett. Council—Gibbon FitzGibbon, M. J. Gibson, A. J. Horne, F. W. Kidd, R. D. Purefoy, J. Spencer Sheill, Alfred Smith, Sir W. Smyly, E. H. Tweedy, T. H. Wilson.

Pathological Section—President, A. H. Benson. Council—William Boxwell, J. B. Coleman, H. C. Earl, L. G. Gunn, W. G. Harvey, H. C. Mooney, A. R. Parsons, R. J. Rowlette, J. A. Scott, A. H. White.

Section of Anatomy and Physiology—President, T. H. Milroy. Council—A. F. Dixon, H. M. Houston, E. L'E. Ledwich, E. P. M'Loughlin, W. H. Thompson.

Section of State Medicine—President, E. J. McWeeney. Council—A. E. Boyd, W. R. Dawson, T. Donnelly, T. P. C. Kirkpatrick, J. A. Matson, W. A. Winter.

#### University of Glasgow.

THE following candidates have passed the third professional examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subjects indicated (P., Pathology; M., Medical Jurisprudence and Public Health):—

Thomas Adam, M.A., M.R.C.S. (P., M.); John A. Aitken (P., M.); Robert R. Archibald, M.A., B.Sc. (P., M.); John B. Baird, B.Sc. (M.); Charles S. Black (P., M.); James E. Black (P., M.); Alexander H. Brown (P.); James A. S. Burges (M.); Donald Downie (P.); Peter Drummond (M.); William D. Dunlop (P.); Thomas S. Fleming (P., M.); Joseph Graham (P.); John R. Haldane (M.); William Hamilton (M.); Angus Macaulay (P., M.); John G. Mackenzie (M.); Thomas J. Mackie (M.); Murdo Mackinnon (M.); Alexander T. McWhirter (M.); Frank W. Martin (M.); Robert S. Miller (M.); Clark Nicholson, M.A. (P., M.); Arthur S. Richmond (P., M.); John I. Russell (M.); Alexander H. Sinclair (M.); James D. S. Sinclair (M.); John T. W. Stewart (P.); John N. M. Sutherland (P., M.); William O. Taylor (M.); James L. Ure (M.); William S. Waterhouse (P., M.); James Williamson (Holytown) (M.); George J. Wilson (M.); John Young (P., M.).

Women.—Mary Alexander, M.A. (P., M.); Marie A. A. Beard (P.); Louisa E. Dodge (P.); Mary A. Pilliet (M.); Jemima Wallace (M.); Marion A. Wylie, M.A. (M.).

The following passed with distinction in the subjects indicated:—

First Examination.—In Botany—Robert H. Williamson, Marguerite Wilson. In Physics—John B. McDougall, James R. C. Mackintosh, Thomas M. Newton, Stanley Robertson, Stuart Robertson, Marion Thompson, Sarah A. Watson, Joseph B. Williamson. In Chemistry—John Sillars.

Third Examination.—In Medical Jurisprudence and Public Health—Thomas J. Markie, James L. Ure.

## NOTICES TO CORRESPONDENTS, &c.

**NOTES.** CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

### SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs 15.12. Messrs. Dawson and Sons are our special agents for Canada.

**SHIR'S SURGEX.**—You should certainly test the urine quantitatively for sugar. A ready way is to take standardised solutions, and note carefully the amount of urine needed to reduce a given amount of Fehling's solution. The percentage is ascertained from these data by means of a table. Messrs. Newton, Gale and Co., London, have a portable urine apparatus, with tables fixed inside the lid. They supply standardised Fehling's solution, Nos. 1 and 2.

**G. R. S.**—In a typical case of acute appendicitis the chief symptoms are those practically of a local peritonitis, namely, pain, tenderness and rigidity of the right lower half of the abdomen, with some amount of fever, quickened pulse and constipation. But, as all surgeons of experience know, an abscess may be present with hardly any symptoms at all.

**THE VICTIM'S FATHER.**—Few women will go through the ordeal of exposing their folly in a court of law in order to punish an extortionate quack; but the threat of exposure is often enough to make a quack disgorge. Consult your solicitor.

**JUVENUS.**—Medical service on the P. and O. affords the opportunity of seeing the world, but literally gives little scope for increasing professional experience.

### WANTED A BRIGHT, DRY CLIMATE.

Two patients from different parts of the country have written us this week, asking if we "know of any place in England, where the climate is bright and dry, the soil gravel, and the water good," as they have been advised by their medical attendant, that it is necessary for them to reside in a district of this nature during the Autumn and Winter months. We confess that we cannot name such a spot off-hand, as climatic conditions have been so adverse of late, that all parts appear to have suffered alike. Can any of our readers speak from knowledge of any district where these conditions usually prevail?

**RHEUMATOID ARTHRITIS.**—A practitioner wishes to record the fact that a case of this disease in a lady member of his family, of middle age, has yielded to prolonged treatment with guaiacoli and iodide of potassium. The case began with *anæmia* and chronic indigestion—gastro-intestinal fermentation.

**JUSTITIA.**—A fee, under the circumstances, might be properly claimed from the husband.

**MEDICAL STUDENT.**—Sir Richard Quain, Bart, M.D., died on March 13th, 1893. He was not the author of "Quain's Anatomy," which was written by a namesake who predeceased Sir Richard.

**L. D. S.**—The choice of an antiseptic is often a matter of individual predilection—there is no such thing as the *best* antiseptic—all those which are commonly employed are equally good.

**M.R.C.S.**—A medical coroner, with some legal knowledge—is undoubtedly a better man for the post, than a legal coroner with no medical knowledge.

## Meetings of the Societies, Lectures, &c.

### WEDNESDAY, OCTOBER 20TH.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.).—4 p.m.: Mr. J. Cantlie: Clinique (Surgical). 5.15 p.m.: Lecture: Dr. W. H. B. Stoddart: The Prognosis of Functional Nervous Disorders.

**NORTH-EAST LONDON POST-GRADUATE COLLEGE** (Prince of Wales's General Hospital, Tottenham, N.).—Clinics: 2.30 p.m.: Medical Out-patient (Dr. T. B. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 p.m.: X-Rays (Dr. H. Pirie).

### THURSDAY, OCTOBER 21ST.

**ROYAL SOCIETY OF MEDICINE (DERMATOLOGICAL SECTION)** (20 Hanover Square, W.).—5 p.m.: Dr. J. M. H. MacLeod: "Cystic Rodent Ulcer" treated by Radium. Dr. H. G. Adamson: (1) Small Follicular Syphilide; (2) Multiple Scars simulating Leucoderma Syphilitica.

**OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM** (11 Chandos Street, Cavendish Square, W.).—8 p.m.: Card Specimens by Mr. B. Harman, Mr. R. Batten, Mr. B. James, Mr. J. H. Fisher, etc. 8.30 p.m.: The President (Dr. G. A. Berry): Introductory Address. Mr. P. Smith: (1) A Note on the Making of Pedigree Charts; (2) A Pedigree of Congenital Discolored Cataract.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.).—4 p.m.: Sir Jonathan Hutchinson: Clinique (Surgical). 5.15 p.m.: Lecture: Dr. G. Carpenter: Heart Disease in Children.

**NORTH-EAST LONDON POST-GRADUATE COLLEGE** (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynecological Operations (Dr. A. E. Giles). Clinics: Medical Out-patient (Dr. A. J. Whiting); Surgical Out-patient (Mr. H. W. Carson). 3 p.m.: Medical In-patient (Dr. G. P. Chappel).

**ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN** (Leicester Square, W.C.).—6 p.m.: Chesterfield Lecture: Bullous and Vesicular Eruption (continued)—V., Herpes; VI., Zoster; VII., Dermatitis petitiiformis.

### FRIDAY, OCTOBER 22ND.

**ROYAL SOCIETY OF MEDICINE (SECTION FOR THE STUDY OF DISEASE IN CHILDREN)** (20 Hanover Square, W.).—4.30 p.m.: Dr. A. Dingwall-Fordyce: Notes on the Pathology of some Live Conditions in Childhood, with a Report of Three Cases. Dr. J. Walter Carr: Case of Pneumococcal Infection in an Infant simulating Generalised Tuberculosis.

**ROYAL SOCIETY OF MEDICINE (EPIDEMIOLOGICAL SECTION)** (20 Hanover Square, W.).—8.30 p.m.: Presidential Address: Dr. James Niven: The Relation of Poverty to Disease.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND** (Lincoln's Inn Fields, W.C.).—5 p.m.: Prof. A. Keith: Specimens illustrating Various Forms of Congenital and Acquired Diverticula of the Alimentary Canal. (Museum Demonstration.)

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.).—4 p.m.: Mr. S. Spicer: Clinique (Ear, Nose, and Throat).

**NORTH-EAST LONDON POST-GRADUATE COLLEGE** (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinique: Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Operations (Mr. W. Edmunds). Clinics: Medical Out-patient (Dr. A. G. Auld); Eye (Mr. R. P. Brooks); Skin (Dr. G. N. Meachen). 3 p.m.: Medical In-patient (Dr. R. M. Leslie). 4.30 p.m.: Lecture: Mr. R. P. Brooks: Squint.

**CENTRAL LONDON THROAT AND EAR HOSPITAL** (Gray's Inn Road, W.C.).—3.45 p.m.: Lecture: Mr. C. Nourse: Middle Ear Labyrinth.

## Appointments.

**CROWE, H. NEVILLE, M.B., Ch.B., M.R.C.S., L.R.C.P.Lond.**, Assistant Surgeon to the Ophthalmic Hospital, Worcester.

**GLASHAN, HERBERT W., M.B.Aberd.**, Assistant Medical Officer to the Natal Government Asylum, Pietermaritzburg.

**HUME, J., M.S., C.M., D.P.H.**, Clinical Assistant to the Chelsea Hospital for Women.

**LAPAGE, C. P., M.D.Vict., M.R.C.P.Lond.**, Lecturer in the Observation of Children and School Hygiene to the Manchester University.

**PRICE, E. W., M.R.O.S., L.R.C.P.Lond.**, Certifying Surgeon under the Factory and Workshop Act for the Narbeth District of the county of Pembroke.

**STADMAN, F. ST. J., M.R.O.S., L.R.C.P.Lond., L.D.S.**, Medical Superintendent of the National Dental Hospital jointly with Mr Sprawson.

## Vacancies.

**Westminster General Dispensary.**—Resident Medical Officer. Salary £120 per annum, with rooms, gas, coal, and attendance. Applications to the Secretary, 9, Gerrard Street, Soho, W.

**Leavesden Asylum.**—Second Assistant Medical Officer. Salary £180 per annum, with board, lodging, and washing. Applications to the Medical Superintendent, Leavesden Asylum, King's Langley, R.S.O.

**Staffordshire County Asylum, Cheddleton, Leek.**—Junior Assistant Medical Officer required. Salary £150 per annum, with board, apartments, and washing. Applications to the Medical Superintendent.

**University College, Cork.**—Demonstrator in Physiology, for Session 1909-10. Salary £150. Applications to the Professor of Physiology.

**Kent County Asylum, Maidstone.**—Fourth Assistant Medical Officer. Salary £175 per annum, with furnished quarters, attendance, coals, gas, garden produce, milk, and washing. Applications to the Medical Superintendent.

**Nottingham General Dispensary.**—Assistant Resident Surgeon. Salary £160 per annum, with apartments, attendance, light, and fuel. Applications to C. Cheesman, Secretary, 12 Low Pavement, Nottingham.

## Births.

**CLARKE.**—On Oct. 13th, at Rosethorne, Allerton, near Liverpool, the wife of Henry Clarke, M.B., M.A., of a son.

**LONGLEY.**—On Oct. 11th, at Strathorne, Salthurn, the wife of J. Alan Longley, F.R.C.S.E., of a daughter.

## Marriages.

**HAIG—BOYD.**—On Oct. 12th, at the Parish Church, West Bainton, Kenneth George, only son of Alexander Haig, M.D., F.R.C.P., and Mrs. Haig, of 7 Brook Street, London to Hester, third daughter of the late George Fenwick Eoyd and Mrs. Boyd, of Moor House, Leamside, co. Durham.

**ODELL—MOORE.**—On Oct. 14th, at Upton Church, Torquay, William Odell, M.D., F.R.C.S., of Fensdale, Torquay, to Ruth Anne, younger daughter of Joseph Moore, of Cuiros, Torquay.

## Deaths.

**CLIBBORN.**—Suddenly, of cardiac syncope, at 12 Bolton Gardens, London, W., William Clibborn, M.D., T.C.D., late of Dorset House, Bridport.

**LEE.**—On Oct. 13th at The Mounts, Thame, Herbert Grove Lee, M.D., aged 69.

**LINDSAY.**—On Oct. 15th, at The Oaks, Botley, Hampshire, Robert Lindsay, M.A., M.B., F.R.C.S.E., late Army Medical Dept., elder son of the late Rev. Robert Lindsay, I.L.D., Minister of Towie, Aberdeenshire.

**TATE.**—On Oct. 15th, at The Coppice, Nottingham, Sophia, wife of William B. Tate, M.D., in her 80th year.

# THE MEDICAL PRESS AND CIRCULAR.

No. 17.

## NOTES AND COMMENTS.

**The Congress on Food.** THE Whitecross Congress that came to an end in Paris on Sunday last must appeal to the medical profession of all countries. Their labours ranged from the colouring matter of confectionery to the precise definition of Camembert cheese, with a whole gamut of things eatable and drinkable between and beyond those two extremes. The Syndicate for the Defence of Pure Coffee lodged an extremely neat protest, which should draw a good deal of international attention in these days of fiscal agitation. "The 120,000,000 francs," they say, "annually levied on the consumers of coffee in France ought at least to guarantee to them the possibility of taking it as they wish to do." And so say all of us who think that he who asks for coffee, and pays for coffee, should have coffee, and nothing but coffee—revenue or no revenue. According to the *Daily Telegraph*, "the unfortunate decision" of the Congress will permit chicory to be mixed with coffee without the buyers being informed of the fact by means of the label, which was originally recommended by this Section. That result hardly augurs well for the future of a pure food Congress, but wisdom may come with maturer age.

**Our Own Pure Food.** THERE is vast room for improvement in the food of the British Islands. It were trite to say that adulteration is rife on all hands, but truth is an essential attribute of triteness. One of the most extraordinary instances is the neglect of the Select Committee of 1899, presided over by Sir Herbert Maxwell, to inquire into the use of chemical preservatives and chemicals in food. In spite of their Report, nothing has been done to check the abuse, and boracic acid is daily used to an enormous extent in milk and other articles of food. The Committee stated at the time of their investigation that half the dairymen in London used preservatives. To secure a really practical and workmanlike Act, the preliminary analysis should be done away with in prosecutions, at any rate where it can be shown to be not absolutely vital to the case. All round us are bogus wines, faked butter, fraudulent adulteration of all kinds carried on wholesale at the expense of the public. Our real want is an automatic prosecuting authority that will replace the present intermittent, feeble administration of the Food and Drug Acts by local authorities.

**Aberystwith Guardians and Medical Fees.** THE Aberystwith Guardians are clearly inspired with a stern determination to save the pockets of the local ratepayers, at any rate, so far as the payment of medical fees is concerned. It would be a matter of general interest

to learn whether their expenditure in other directions is characterised by a parsimony resembling that shown at a recent meeting of the board. On the occasion in question, the vice-chairman, Mr. Edwin Morris, drew attention to a bill sent in by Dr. Bonsall, their medical officer, in which a charge of £1 2s. 6d. was made for certifying nine certified imbeciles. It appeared that one of the female imbeciles had been visited by another medical man with a view to her removal to the workhouse, but he was unable to satisfy himself that she was a certifiable lunatic, although on the borderland of insanity. The underlying implication, so far as can be gathered from a newspaper report (*Liverpool Daily Post and Mercury*, October 12th), appears to have been that, the woman's insanity being somewhat doubtful, the fee should not be paid for her medical examination. Eventually the Guardians passed the account, and the medical officer received his princely fee of half-a-crown for each case of lunacy certification, one of the most skilled and responsible duties a medical man could be called upon to discharge.

**A Half-guinea Chloroform Fee.** BUT the ball had been set rolling, and the Guardians of the Aberystwith poor had another opportunity of tightening the purse-strings. An account of one guinea was presented

by a medical man who had been called in to give chloroform to a pauper in the House. The case appears to have been one of midwifery, for which Dr. Bonsall received fifteen shillings, his contract fee. The Guardians objected to paying a guinea, and the House Committee offered to pay 10s. 6d. chloroform fee, in accordance with a resolution passed some time previously. Dr. Bonsall naturally asked what he was to do, supposing no outside medical man would attend for that fee. A member stated in answer that the Local Government Board had informed the Guardians that the medical officer was responsible for all the cases, and any assistance he required he would call in upon his own responsibility, leaving the payment to the discretion of the Guardians, subject to the approval of the Local Government Board. It seems that Dr. Bonsall has acted as medical officer for nineteen years, and that the guinea fee has been always hitherto paid. The Guardians, however, resolved in future to offer half-a-guinea for such assistance. It is to be hoped that no medical man in Aberystwith or the district will be found willing to accept so paltry and inadequate a fee for so arduous and responsible a professional duty.

**A Stomach Ball.** AN interesting case of the formation of a metallic ball in the stomach was reported the other day by the Medical Officer of Aston. An old woman who died under his care was found post-

mortem to have a hard globular mass about the size of a cricket ball in the interior of the organ mentioned. The explanation was that deceased had worked in the wire trade and had been in the habit of swallowing small particles of copper wire, which had gradually accumulated to form the ball. The whole subject of these accretions is interesting. They are most common in cows, when they are, as a rule, composed of a firm felted mass of short hairs that have been licked off the coat of the animal. At times they are found in the horse and other animals, and occasionally reach a considerable size. The danger of such a foreign body in the stomach does not appear to be excessive. In mankind the condition most frequently occurs amongst lunatics, especially those who are in the habit of chewing or swallowing string, hair, cotton, and so on. It has been reported amongst sempstresses who have been accustomed to bite off the ends of their sewing thread. Occasionally jugglers accumulate a great felted mass of metal, glass, and other objects, sometimes to the extent of several pounds weight. Under these circumstances the stomach is often displaced downwards, and may reach the pelvis. Death not uncommonly results, even when the mass is removed by operation.

## LEADING ARTICLES.

### INEVITABLE DEATH AND THE COMPENSATION ACTS.

THE working of the Workmen's Compensation Act has revealed some of the practical difficulties that are inseparable from the application of fresh legislation to complicated social relations. From the first publication of the measure we asserted that sooner or later employers would demand a certificate of physical soundness from their employees. It is obvious that a decrepit person, or one handicapped by some defect of body or mind, would be more prone to accident, less capable of recovery, and more liable to become involved in secondary complications that affect less resistant individuals. A case in point was investigated recently at a St. Helens inquest, where a man aged thirty-eight years, for three years had been attended by a medical man for chest trouble, and latterly for consumption. It was shown in evidence that early in the present year deceased had injured his knee while working in a colliery, and he was off work in consequence for a period of twelve weeks. When he began work again he told his relatives that his employers had found him a light job. On April 8th he received another injury through a runaway pony in the pit, whereby he sustained a wound at the side of his head. On that occasion the account he gave to his friends was that he had been knocked down in the pit and run over. After the second accident he was in the St. Helens Hospital ten weeks, then at home a month, and afterwards in the Providence Hospital, where it is to be presumed he died, although the fact is not mentioned in the report of the inquest given in the *Liverpool Daily Post and Mercury*. The post-mortem examination showed that the wound at the side of the head was healed, and there were no signs either of fracture or of injury to the brain. The body was terribly emaciated, and death was due

to consumption. That view was held both by the medical attendant of deceased and by the medical man who represented the colliery proprietors. The latter said emphatically that the condition of the left lung was such that it was a wonder the man had lived so long. The point of difference between these two witnesses was whether or not death had been accelerated by the accident. While the one held that the accident had shortened life, the other failed to see how the injury could in any way have hastened death. With a view of shedding fresh light on the problem, another medical man was sent for, but his evidence did not materially aid the Court in arriving at a decision. This third expert witness pointed out that the man must have benefited very considerably from the hospital treatment and good nourishment. On the other hand, the injury and the subsequent loss of blood would render his condition less favourable. On being further pressed, the witness said, as a matter of opinion, that in all probability the injury must have devitalised deceased and rendered his resisting power less, and so hastened death; but that view was not capable of proof. The jury unanimously decided that death was due to consumption, but it was accelerated by the injury accidentally received. As this case will possibly, or probably, be the subject of further legal procedure, it cannot be discussed further here. Upon the general question, however, as to the employment of persons suffering from severe constitutional maladies, it may be permissible to offer a few remarks. Clearly, a man wasted, let us say, by diabetes or some malignant internal malady, would be less alert than a healthy person and more liable to meet with accidents. More than that, his judgment would be probably impaired owing to an impoverished blood supply. Then, again, he would be less resistant to shock and to the secondary complications of wounds than the average normal individual. From these and other considerations of a similar kind that could be brought forward it seems impossible to avoid the conclusion that, from a selfish point of view, the employer will run least risk both as to the occurrence of accidents and as to the severity of their results when he causes to be made a careful preliminary examination of the state of the health before engaging any workman. There is little room for sentiment or romance in the Workmen's Compensation Act, and it seems likely that even if the employers do not generally insist upon the preliminary medical examination, that sooner or later the step will be taken by the insurance companies as a necessary safeguard of their own interests.

## CURRENT TOPICS.

### Sociology and Evolution.

IN his opening lecture at the School of Sociology last week, Major Leonard Darwin dealt with questions that have been thoroughly discussed in these columns, although, no doubt, they still need reiteration before popular audiences. No medical man needs to have pointed out to him the fact that strenuous efforts are now being made in many

directions to counteract the natural workings of the evolutionary process on the human race, with the result that many sickly and feeble people survive to become parents, who formerly would have perished unmarried. It is a question, as Major Darwin suggests, whether, as a nation, we are now deteriorating in both body and mind. If we are not now a decadent nation, this, it is certain, may soon be our fate if due effort be not made to combat the ultimate evil results attendant on our increasing civilisation. It is quite evident that the study of the future effects of present reforms, and of new customs and conventions, is especially imposed upon us in this epoch of rapid changes. Major Darwin's sole practical suggestion is contained in a somewhat vague statement with regard to feeble-minded girls, who, he thinks, might have imposed upon them a certain curtailment of their liberty, we presume in the direction of matrimony. There cannot be the least doubt that civilised society is consciously, or unconsciously, carrying on a gigantic system of artificial selection, which favours, to a great extent, the survival of the unfit. Major Darwin, in illustrating this fact from several points of view, did not refer to the probable effect of the practice of limiting the number of children when carried to the extent now universally customary in France. The first one or two children are safeguarded through childhood to adult age, and then provided with mates in matrimony. Virtually, no French man or woman marries "for love," and however unfit be the girl for maternity—within very wide limits—a husband is found for her if she possesses a sufficient fortune. However physically and mentally fit a penniless girl may be no Frenchman will take her as a wife—as a barren mistress it is a different question. If, on the other hand, families were large, and the question not one of money alone, the girls and boys most fitted would gain mates, and evolutionary forces would have fair play. This is a point that has not been touched upon by our able correspondents, who so strenuously insist that the stationary population forms strong evidence of the decadence of the French race.

#### Lombroso's Achievements.

VERY few latter-day men of science have got through the amount of work performed by the late Professor Lombroso, and probably none who has wrought so strenuously has left so poor a record of solid achievement. Lombroso's work in physiology and criminology has been valuable in its suggestive quality, but of little use in establishing solid facts upon which generalisations could be based. His attempt to prove that all criminals are degenerates and to establish an anatomical theory of crime, did not succeed; but the fact upon which he insisted, that great classes of habitual malefactors are of an innate criminal type, and as such are not amenable to reason, or punishment, is now generally accepted. Some of our recent legislation has been evidently influenced by Lombroso's teaching—especially the laws providing for the preventive detention of those leading persistently dishonest or criminal lives. Lombroso had more than a touch of scientific genius, but he was always in too great a hurry to publish, and his reputation would have stood higher if he had sifted out, and presented to the world the valuable grains of new knowledge that were always discoverable amid the

mass of chaff which enveloped them. Lombroso's scientific qualities were never perhaps better manifested than in the work he performed in 1872 when he demonstrated the true character of pellagra, a disease then widely prevalent among the peasantry of Lombardy. The disease began in the skin, and afterwards affected the brain and nervous system. Lombroso discovered that the malady was due to diseased maize, the staple food of the people. He extracted the poison from the grain, and infected animals with it. His discovery was received with derision, and something very like a persecution was started against him by the landowners whose interests were affected. In the end the validity of Lombroso's discovery was fully established. Berthelot, the French chemist, whose attention was drawn to the matter, entered upon an independent inquiry and proved conclusively that the diseased maize contained a toxin which closely resembled strychnine, whilst differing from it in some important particulars.

#### Malarial Prevention in India.

UNDER this heading a month ago, we briefly summarised the views of Sir Ronald Ross which he had communicated to the *Times*, with regard to the then impending Imperial Malaria Conference. Sir Ronald Ross expressed the fear that too much importance might be given perhaps to quinine prophylaxis, and too little attention directed to the anti-mosquito campaign. Whether or not the Conference, which was held last week in Simla, was influenced by Sir Ronald's arguments, it has certainly adopted fully his ideas, without, however, neglecting other considerations. The Conference recommends, first of all, the appointment by the Government of India of a scientific investigation committee, to be linked up with special organisations for dealing with malaria in each province. Practical measures are next insisted upon, the extirpation of anopheles having among these a first place. Minor drainage operations; the restriction of wet cultivation near towns; the introduction of fish into tanks and other collections of water, and the oiling of small collections of water which cannot be filled up, are all aimed at the end Sir Ronald had in view. With regard to the use of quinine, detailed recommendations were made by the Conference to facilitate its sale in small quantities, and to induce private vendors to engage in its distribution. The Conference laid stress upon the importance of education, and recommended that committees of officials and non-officials, should be formed to spread among the people knowledge regarding malaria and the measures which it is possible to take against it; also that the subject should be taught in the schools.

#### The Royal College of Surgeons in Ireland.

AT the opening of the winter session of the College of Surgeons in Ireland, last week, the President, Mr. Lentaigne, again drew attention to the serious dangers which threaten the future career of the College. As has already been stated, the College is without endowments or funded property to any extent, and is dependent for the greater part of its income on the fees paid in the School. The School is now threatened with competition of an unaccustomed character. The position now is, that, whereas the School

of the College of Surgeons is practically dependent on fees paid by its students, all the other schools in Ireland either have considerable endowments or Government grants. In fact, of the six medical schools in the country, four are in direct receipt of Government funds, while the fifth, that of Trinity College, has fair endowments from other sources. In particular, the rivalry of the new and richly endowed University College School is likely to prove serious. There was, we understand, some fear that the newcomer would attempt to undersell its older rivals by lowering the scale of fees, but we are glad to observe from certain preliminary statements issued that the fees are to be approximately the same as those demanded in other Irish schools. The next few years are likely to be critical in the history of the Irish College, and the President and Council may be assured of the sympathy of their professional brethren in their attempt to maintain the only school in Ireland whose management is entirely in the hands of the profession.

#### Campaign against Tuberculosis in the United States.

IN a popular address, some months ago, Sir Frederick Treves expressed the opinion that the time was coming when mortality from preventable diseases which now count their victims by the hundred thousand annually, would become as rare in these islands as death from the bite of a rabid wolf; and there can be no doubt that when the nations shall have brought their sanitary administration up to the level of scientific knowledge and achievement, many deadly maladies, up to lately, regarded as calamities against which no protection was possible, will be extinguished. Plague and cholera, it is safe to say, will never again occur in wide epidemic form in Western Europe; science has taught the sure methods of prevention; and application of similar methods will surely, in time, render such diseases as typhoid fever and tuberculosis and rickets—the scourges of the poor—equally uncommon. The prevention of many diseases has been reduced to a mere matter of expense, and this especially applies to tuberculosis. For instance, if funds were available it might be possible to stamp out tuberculosis among cattle, and thus at once put an end to a great source of infection; whilst the isolation of human subjects in the infectious state is also a question almost entirely of expense. The facts have become more fully recognised in the United States than anywhere else in the world. We learn from a telegraphic dispatch from New York in the *Times* that appropriations amounting to more than £800,000 for this purpose have been made by State legislatures during the present year; that £600,000 at least will have been furnished by counties and municipalities, whilst the Federal Government has granted nearly £200,000 for the support of sanatoria. Sanatoria have been erected in twenty-seven States, and many more have been authorised. Besides all this, a large amount of work is being carried on by benevolent and voluntary organisations. One fraternal society of workmen is building a tent city of 1,000 acres near Colorado Springs, and

numerous other similar bodies are following this example on a small scale, whilst a wide propaganda of education is being carried on which promises to make the people all fully conversant with the measures necessary to escape the dangers of “the white plague.” If this work be continued in the same spirit, tuberculosis, it may well be believed, will be before long discoverable only in sporadic cases through the territories of the United States.

#### Is Lunacy on the Increase?

THE evergreen question amongst journalists and magazine writers is, whether or not lunacy is on the increase amongst our population. If we judge from undigested figures pure and simple the outlook would indeed be of a most discouraging kind, both as regards progress from year to year and from generation to generation. There are, of course, many obvious fallacies in modern asylum returns as compared with those of our grandfathers. Diagnosis is now more complete and general, and village idiots and imbecile paupers are nowadays placed in special institutions. The less obvious fallacies are those with which we are mainly concerned, namely, those that explain away or minimise the yearly increasing figures of to-day. The recent returns of the Asylums Committee of the London County Council, for instance, show 26,648 insane persons chargeable to the metropolitan rates on January 1st, as compared with 26,170 a year before. The average annual increase for the past 19 years is 506, an increase out of proportion to the normal increment of population. The increase is explained by the Committee as in previous years, that much of the apparent increase is to be explained by the lowered death-rate and the consequent accumulation in the asylums of chronic cases; also in part to a more comprehensive registration, and not necessarily to a greater prevalence of insanity among the population. The lessening of the death-rate has been much greater among the males than females, being in the proportion of 4 or 5 per cent. in the men to 1 per cent. in the women. Both the recovery-rate and the death-rate for 1908 were lower than the corresponding rates for 1907, and the total number of direct admissions to the London County Asylums during the year exceeded the discharges “recovered” and deaths by 894. The actual number of patients for whom the London County Council was directly responsible in the asylums was 19,716, of whom 8,578 were males and 11,198 females.

#### Inspection of Schools in Ireland.

FOR some inscrutable reason, when Parliament established a system of medical inspection of schools in England, Ireland was not included in the Act, though, unfortunately, there is reason to believe that medical inspection is more needed in Ireland than in England. Last year, when the Board of Intermediate Education resolved to introduce, for the first time, a system of inspection into Irish secondary schools, we strongly urged the appointment of one or more medical men as inspectors. Unfortunately, our advice was not taken. Nevertheless, we had reason to hope that inspection by educated laymen would exert a salutary influence

on the domestic and hygienic arrangement of the secondary schools of the country, as it was assumed that the inspectors would not be limited in their scope to mere inspection of teaching, but that surveillance of the entire school system—including domestic arrangements, games, time-tables—would come into their duties. To such a wide sphere of activity a sudden but strong opposition has arisen. A large number of boarding-schools have protested against the system of inspection going beyond the class-rooms, and the protest has been supported by some in high positions of influence. We can only say that we hope the Intermediate Board will show itself as determined to have a thorough system of inspection, as it has shown itself in many less obviously righteous decisions. We consider the hygienic system of the school of much more importance to the welfare of the pupils than the instruction they receive, and we therefore believe inspection of the former the more important. We regret that the Board has left itself without the assistance of those best qualified to judge of matters of hygiene.

### **Peculiar People, Christian Scientists and the Law.**

THE law has been so clearly laid down in late years by judges in criminal courts that there should remain little doubt in the minds of leaders of eccentric sects like the Peculiar People and the Christian Scientists as to their responsibilities when undertaking the treatment of sick people, and the cases in which a charge of manslaughter is preferred should in future become more and more rare. The law is very much in accord with common sense. There is no law to compel people to call in medical help when ill. They may be suffering from some surgical affection curable by a simple operation, but certain to end fatally without the aid of the surgeon's knife, and if they elect thus virtually to commit suicide they cannot be interfered with, nor can their friends or attendants be made responsible for not pressing or forcing medical services upon them. Responsibility would, however, arise if the patient were obstructed in calling in a doctor. If the patient were mentally incompetent or imbecile the custodians would be bound to seek medical advice under penalty of a charge of manslaughter in the event of a fatal result. The Children Act makes it imperative to call in a doctor in cases of serious illness, and this statute would render certain a conviction for manslaughter in any case where medical services had not been sought, and it was proved that the death might have been averted by timely treatment.

## **PERSONAL.**

THE King visited Norwich on Monday for the purpose of presenting colours to, and reviewing the Norfolk units of, the Territorial Force, and of laying the corner-stone of the new wing of the Norfolk and Norwich Hospital, and was enthusiastically welcomed.

HIS MAJESTY KING EDWARD VII. by connecting an electrical current in West Dean Park, Chichester, England, on Thursday last, caused the doors of the Royal Edward Institute (for the study and cure of tuberculosis), Belmont Park, Montreal, to open, and the Royal Standard was hoisted at the King's touch.

PROFESSOR PETER THOMPSON, M.D., Ch.B., of King's College, has been appointed professor of anatomy at Birmingham University, and will shortly take up his duties there.

DR. HENRY JELLETT has been elected King's Professor of Midwifery in the School of Physic in Ireland, Trinity College, Dublin, in succession to Sir Arthur Macan, deceased.

MRS. JOHN NIXON "well and truly" laid the foundation stone of the new wing at Cardiff Infirmary on last Thursday afternoon, the chairman (Major-General Lee) invited donors to place gifts on the stone.

DR. JAMES PORTER, M.A., M.D., Medical Director-General of the Royal Navy, who has been attending the Naval Medical Conference in Washington, has returned to London.

PROFESSOR T. H. BRYCE, successor to Professor Cleland in the Chair of Anatomy in the University of Glasgow, was formally introduced to his students on the 18th inst., by Principal Sir Donald MacAlister.

DR. ANDREW J. HORNE has been elected President of the Royal College of Physicians of Ireland, and Dr. E. MacDowell Cosgrave, Vice-President. The full list of officers elected last week will be found in another column.

AFTER the Harveian Oration at the Royal College of Physicians of London delivered by Dr. Savage the Moxham Medal was presented to Sir William Gowers and Weber-Parkes prizes to Dr. Cormack Wilkinson and Dr. Arthur C. Inman.

AT the same time the President of the College conferred *in absentia* the Baly Medal upon Professor Emil Fischer, of Berlin, who was unable to be present.

WITH the object of recognising the sterling worth of Dr. James Lloyd, who has been resident in Llanbradach for fourteen years, the tradesmen and others entertained the worthy doctor at a banquet at the Llanbradach Hotel. A large number of guests were present. Dr. Lloyd was presented with an address and several handsome presents.

THE Committee in charge of the testimonial to Professor Ogston desire to intimate that members of the medical profession wishing to contribute should send their subscriptions to the honorary secretary, Dr. Mackenzie Booth, 1 Carden Place, Aberdeen, at an early date, as the subscription list must soon be closed.

DR. JOHN HODGSON WATERHOUSE, M.D., of Avenue Victoria, Scarborough and formerly of Maltby Grange, Rotherham, late house surgeon to the Liverpool Northern Hospital, and consulting surgeon accoucheur to the Sheffield Royal Hospital, who died 26th August last, aged 78 years, left estate of the value of £43,997 10s. 9d., of which the net personalty has been sworn at £43,927 10s. 9d.

MR. ROBERT JONES, F.R.C.S.E., hon. surgeon to the Royal Southern Hospital, Liverpool, has been awarded by the Royal College of Physicians, Edinburgh, the Victoria Jubilee Liston Prize of £100 for the greatest benefit done to practical surgery by a Fellow or Licentiate of the college during the quadrennial period from 1905. The prize was instituted by the late Dr. Robert Halliday Gunning.

DR. J. K. COUTTS, of Valentine House, Blackley, was in Chapel Lane when a heavily laden lorry collided with his carriage. The doctor and his man were thrown into the street, while the carriage was smashed. Dr. Coutts was assisted by Sir Frederick Cawley and Mr. Whittaker, of Heaton Mills, who happened to be in the district, and after some attention he was able to resume his round. His attendant was badly shaken.

# A CLINICAL LECTURE ON HYPERTROPHY OF THE PROSTATE AND ITS TREATMENT.

By Prof. PAUCHET,

Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

HYPERTROPHY of the prostate gland is very common in men over 55 years of age. A third part of aged men present a large prostate, but only 5 per cent. suffer from urinary troubles requiring treatment. Eight times out of ten this hypertrophy is due to glandular degenerescence of the organ bearing on the two lobes, and is ovoid in shape, with the large end reposing on the middle aponeurosis of the perinæum, while the small extremity bulges into the cavity of the bladder.

The volume of the diseased prostate is that of a walnut or a small orange, and its weight is between one and three ounces.

The prostatic portion of the urethra is elongated, and a catheter introduced into the canal must be pushed almost to the extremity to withdraw the urine. Developing towards the bladder, the prostate pushes up the vesical orifice, creating a *bas fond* behind it; this *bas fond* never empties completely at the moment of micturition.

As soon as the lobes become hypertrophied, the flow of urine is more or less impeded; the bladder makes an effort to overcome the obstacle, thus producing compensating hypertrophy of the muscular coats. But soon these repeated efforts result in vesical fatigue, the bladder loses gradually its contractibility and ceases to empty itself completely.

This incomplete evacuation amounts, at the beginning, to a residue of four or five ounces of urine which remain after each micturition, representing incomplete retention without distension. But if the vesical paresis increases, the bladder will only empty itself by engorgement. The flow occurs not only at the moment of micturition but also in the intervals (incontinence). This condition constitutes distension, distension which attains not only the bladder but the ureters and even the hyx.

As regards the anatomical varieties of prostatic disease, one out of ten cases is undergoing epitheliomatous degenerescence, but of slow development (one, two or four years).

Hypertrophy of the prostate is admirably disposed for decortication; each lobe is provided with its own capsule, while both lobes, together with the prostatic portion of the urethra which runs between them, are enclosed in a common capsule, from which they are separated by a layer of cellular tissue, facilitating singularly enucleation. The musculo-fibrous envelope protects the perivesical cellular tissue against infiltration of urine and pelvic cellulitis, while retraction of this tunic obliterates the veins running through it, protecting thus against hæmorrhage or infection operation.

*Treatment.*—Every patient who, after micturition, presents a residue of four ounces, should use a catheter regularly, entering thus on catheter-life. Where the residue does not exceed four ounces the patient should use the instrument but once a day, and that before going to bed; this precaution will give him several hours sleep. If the residue reaches six ounces the catheter should be used twice a day, while for ten ounces it should be

passed every three or four hours. The patient should never wait for a pressing need to evacuate his bladder, otherwise vesical congestion and cystitis might result.

The best catheter is the soft catheter of Nélaton, but if it cannot force the obstacle, the catheter à bequille should be employed.

If a rough passage of the instrument provokes hæmorrhage or a rise in temperature, or if the patient presents symptoms of cystitis (cloudy ammoniacal urine), the catheter should be left *in situ*. The method is simple: a piece of gauze bandage is rolled around the penis and maintained with a few stitches; the instrument is introduced as far as the neck of the bladder and no farther, otherwise it would not be easily borne; four little strings of soft cotton thread are tied around the catheter at its point of exit and fixed to the four sides with sticking-plaster. The end of the instrument is kept closed by a small wooden peg or a glass stopper when possible.

According as the urine is clear or cloudy, the bladder will be washed out more or less frequently. The catheter will be changed every twenty-four or forty-eight hours, unless a false route has been made, in that case it should be left in only five or six hours.

Where palliative treatment is insufficient and the age of the patient is no counter-indication, prostatectomy should be proposed. The gland can be reached either through the perinæum or through the bladder. The former method is reserved for stout subjects, in whom the organ can be felt generally low down.

The prostate might be compared to the fruit of a chestnut tree, containing two nuts; the operation of prostatectomy consists in enucleating these two kernels by leaving behind the green pericarp or fibrous envelope. This common tunic forms a closed barrier against urinary infection and infiltration, and it is to this anatomical particularity that prostatectomy owes its benignity. The more the lobes increase in size, the more their individual capsules are distinguished from the common envelope and the more easy is the enucleation.

The bladder is first washed out with a weak solution of oxygen water, after which two or three syringes of air are injected in order to distend the bladder, and a tight bandage is placed on the penis to prevent the escape of the air. The incision commences at the pubis and extends up the middle line for two or three inches, in stout persons the incision should be longer. When the linea alba is brought to view and cut, the recti muscles are separated with the closed scissors and the peritonæum pushed upwards; at the bottom of the wound the bladder appears, easily recognisable by its grey and rose aspect and its two vertical veins.

The bladder is incised for about half an inch and the index of the right hand passed into the cavity. If any calculi are present they are removed and the bladder washed with an antiseptic solution (oxygen water). The index of the left hand, armed with a rubber finger hood, is

introduced into the rectum to sustain the prostate and push it forward. The right forefinger attacks the prostate through the vesical cavity at the most salient point and close to the orifice of the urethra. Generally the pressure alone of the finger suffices to erode the mucous membrane. If the tunic resists, the operator can fix on his finger an artificial metallic nail. As soon as the membrane is severed, the finger comes in contact with the adenomatous mass, it follows its surface, finds a point where it can pass under the common covering and enucleation begins. When the right finger, aided by the left in the rectum, has passed all around the tumour, the latter becomes mobile, and is only retained by the urethra as an apple to the tree by its stalk. Another effort of the finger tears the urethra, and the mass rolls freely into the vesical cavity. The rupture of the canal takes place right behind the veru montanum, consequently only a small portion of the urethra is suppressed, and as the prostatic segment is always considerably elongated, the solution of continuity is of little consequence, which, in any case, heals rapidly without leaving trace of stricture.

The two post-operative complications to be feared are infection and hæmorrhage. Cellular infection of the pelvis is rendered impossible by the method of intra-capsular enucleation, but general infection remains always possible through the numerous veins which surround the prostate; the same veins may bleed freely, consequently, after enucleation, retraction of the prostatic cavity should be obtained, and this is effected by vesical and rectal massage executed by the fingers for a few minutes.

Drainage is assured by Freyer's large tube, about  $3\frac{1}{2}$  ins. in length, and furnished with parallel oval holes. The tube is introduced into the bladder for about half an inch, and no farther, on no account should it touch the *bas fond* of the bladder. The business of this tube is simply to keep open the lips of the wound, and should be withdrawn between the third and tenth day. It sometimes happens that hæmorrhage sets in from the tenth to the fifteenth day in patients where the incision healed too rapidly; in that case, the wound should be reopened and a smaller drain inserted.

The age of the patient is a considerable factor in prostatic disease, as well as his general condition. As regards the latter, a whole variety of chronic affections may be encountered: heart disease, arterio-sclerosis, softening of the brain, chronic bronchitis, albuminuria, diabetes, obesity, voluminous hernia, etc. In such necessarily short-lived persons, prostatectomy can be only indicated where all other means had failed.

As to the variety of the lesions of the prostate, the rectal touch permits to diagnose if the dysuric accidents are due to cancer, to glandular prostatitis, to peri-prostatitis, or, in fine, to adenoma. This latter form is the most amenable to surgical treatment.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by James Donelan, M.Ch., M.B., Chevalier of the Crown of Italy, Laryngologist to the Italian Hospital, London. Subject: "Suppuration in the Accessory Nasal Sinuses."

SIR FREDERICK TREVES, Bart., G.C.V.O., Sergeant-Surgeon to His Majesty the King, was last Thursday evening the guest of the Liverpool Philomathic Society at their 84th annual dinner, held at the Adelphi Hotel. He devoted his address to describing the declining use of the hands in various industries.

## ORIGINAL PAPERS.

### SIX CONSECUTIVE CASES OF APPENDICITIS, OPERATED UPON, WITH NOTES THEREON OF PRACTICAL INTEREST TO THE GENERAL PRACTITIONER.

By S. J. ROSS, M.D., CH.B.,

Senior Assistant Surgeon to the Bedford County Hospital.

CASES of appendix mischief are nowadays so very common that some of your readers may wonder why I should bring the subject before their notice. I do so, as in cases of appendicitis, just as in other abdominal cases, you can never prophecy, with any hope of certainty, the condition with which you will have to deal.

The first patient was a healthy man, æt. 24, who for three years had been frequently troubled with "bilious attacks," for which he never sought medical advice. The last attack was, however, a more severe one than the previous ones, and he was compelled to seek medical advice. I saw him on the third day of the attack. His temperature was only 99°, but his pulse-rate was 120; his right thigh was flexed upon the abdomen, he complained of pain in the region of the umbilicus, and there was marked tenderness in the right iliac fossa. I diagnosed appendicitis and advised an immediate operation, to which he readily consented. I made the usual incision, which is one, the centre of which is a little below a line passing through the junction of the outer and middle third of a line drawn from the umbilicus to the anterior superior iliac spine of the right side. There were many adhesions, which made it a matter of considerable difficulty to bring the cæcum up to the surface of the wound. While carefully separating these adhesions I came across a stercolith. I then found the appendix, which was only  $1\frac{1}{2}$  inches in length, and, having freed it, I removed it close to the cæcum. I then buried the stump in the cæcum by a purse-string suture. I closed the wound in three layers. Upon opening the appendix after the operation, I found that the lumen was obliterated at the tip for an inch, and that there was a perforation close to its base, through which, doubtless, the stercolith had escaped. The patient made an uninterrupted recovery.

The second patient was a female, æt. 19, who had had three definite attacks of appendicitis. The last attack was ushered in by diarrhoea, and vomiting was very frequent. There was marked tenderness over the appendix region. Rectal examination revealed the presence of a large abscess. The abdomen was opened by the usual incision, and a large quantity of evil-smelling pus was released. As the condition of the patient was satisfactory, I proceeded to search for the appendix, which I found buried in adhesions; having freed it, I removed it. The abscess cavity was very thoroughly swabbed out with 1 in 500 biniodide in alcohol solution. A posterior drain was then inserted, through an incision made just above the iliac crest. The anterior wound healed by first intention. The drainage tube was removed from the posterior wound on the sixth day, when there was no further discharge. In fourteen days the posterior wound was healed.

The third case is that of a female patient, æt. 25. Six months before the present attack she had her first attack. She complained of pain over the appendix, and a lump the size of a pigeon's egg was easily felt. Upon opening the abdomen, a hard mass was felt in the appendix region, which was far larger than external examination had led

us to suppose. The cæcum was identified, and the mass, consisting of the appendix and enlarged glands buried in adhesions, was brought up as near as possible to the surface of the wound. A piece of inflamed appendix was dissected out from its bed of adhesions with the fingers. This proved to be a bend in the appendix near its base. The remainder of the appendix dipped down into the pelvis, the tip hanging over the pelvic brim. The appendix was dug out of its bed of adhesions with great care and removed, the stump being buried in the cæcum. The wound was closed in three layers, a small wick of gauze being inserted into the lower end, and a loose stitch being left ready to be tied when the gauze was removed. The wick drain was removed in twenty-four hours as there was no discharge, and the loose stitch was tied. The wound healed by first intention throughout its entire extent.

The fourth case was that of a youth, æt. 25. I had attended him through four definite attacks of appendicitis, the main symptoms of which were vomiting, abdominal pain, marked tenderness over the right iliac fossa, and constipation. Fever was present in all the attacks. I repeatedly urged him to submit to operation, but he could not spare the time necessary from business. However, his last attack was very acute and he consented to have the operation.

I made the usual incision over the appendix. The appendix was found with ease, its tip reaching across the middle line to the left side. It was very inflamed and its outer surface covered with lymph. I removed it and buried its stump in the cæcum. The abdominal wound was closed in three layers. The patient made an uninterrupted recovery. Upon opening the appendix, the mucous membrane was found to be very injected, and in places hæmorrhage had occurred; the wall of the appendix was thickened and the contents were purulent.

The fifth case was a female, æt. 20, who had complained of pain in the region of the right hip for a year. She had been told that she was suffering from hip disease. The hip-joint was found to be normal. There was tenderness in the right iliac fossa and also in the right loin. I explored the appendix by the usual incision. The cæcum was readily discovered. The appendix was found lying behind the ascending colon, fixed by adhesions and perforated in its centre. I freed it and removed it, burying the stump in the cæcum and covering the area with great omentum. The patient made an uninterrupted recovery.

I was called into consultation to see a boy, æt. 8, with the following history:—Five days before I saw him he had a "bilious attack," which was treated by home remedies. Two days after this he was seized with abdominal pain and vomiting, and his medical attendant was called in. He had also a rigor lasting half an hour. When I saw him his condition was as follows:—His abdomen was very distended. There was marked tenderness over the right iliac fossa, and a mass to be felt in the appendix region. His right thigh was flexed upon his abdomen. Vomiting was very frequent. His pulse was imperceptible, his extremities were cold, and it was obvious that operation was out of the question. He died a few hours after my visit.

#### REMARKS.

These cases teach us how very important it is that the layman should, in cases of abdominal pain, consult a medical man, and not trust to his own powers of diagnosis.

The first case illustrates this point very clearly. If this man had not had this severe attack, doubtless he would never have consulted a medical man, and, considering the state of his appendix as

revealed at the operation, another neglected attack might have ended in a fatal attack of septic peritonitis.

Temperature is of very little value as a guide in cases of appendix trouble. We must rely upon the pulse.

With regard to the second case, I think that it is important to note that diarrhoea occurring early in a case of appendicitis often points to the presence of pus. *In every case of appendicitis a rectal examination should invariably be made.*

In every case of appendix abscess we are justified in spending some time in searching for the appendix, and endeavouring to remove it if the patient's condition be satisfactory. If we leave a diseased appendix, we never know when a fresh infection may be lighted up.

In cases of appendix abscess a posterior drain can easily be put in, and in many cases, after careful cleansing, the anterior wound can be safely closed.

An anterior drain has several drawbacks. It is in the wrong position for satisfactory drainage, and a hernia is apt to develop subsequently at the site at which drainage was employed.

The third case reminds us of a fact which we are apt to forget: that we can never safely judge of the size of an abdominal swelling by an examination through the anterior abdominal wall.

The fifth case emphasises the fact that pain over a certain place does not always indicate that this place is the site of the disease. We must make a diagnosis very often by a process of exclusion. It is also interesting to note that this patient had a perforation at some time previous to the operation, and it is also to be noted that she complained of pain in the right loin, and that the appendix was placed behind the ascending colon. Possibly the position of the appendix saved her from an acute and fatal attack at the time of the perforation.

The sixth case is an example of neglected appendicitis, which we all deplore. Had the boy's parent called in a medical man on the first day of illness, in all probability the patient would have been alive now. As it was he never had a chance given to him.

#### GENERAL REMARKS.

I am confident that the most useful guide as to the progress or otherwise of these cases of appendicitis is the *pulse*. A rapid pulse, or a pulse which is increasing in frequency is of ill omen. The temperature is of very little value as a guide compared with the pulse. I have drained a large appendix abscess, and removed a sloughing appendix, when the patient's temperature has been normal, or even sub-normal. I should lay it down as a rule to which there are no exceptions that once a patient has had a definite attack of appendicitis, that it is our duty, during the quiescent period, to remove the appendix.

In every case of appendicitis a rectal examination should be made. Well do I remember the case of a boy, æt. 12, whom I saw on the fifth day of an attack of appendicitis. His temperature was normal, but his pulse was 130. I made a rectal examination and found a large abscess. This we drained, and the boy made a rapid recovery.

It is extremely bad practice to administer opium in any form, and even in minute doses, to a patient suffering from appendicitis, unless we are prepared to operate without delay. It masks the symptoms, but, of even greater importance, it controls the circulation and destroys our most reliable guide as to our patient's condition—the pulse. We shall not stray far if, in operating upon these cases, we take "quick in, quicker out"; to mean, we must reach the appendix with all speed, and, having found it, we must remove it as quickly as we

possibly can while ensuring the safety of our patient.

The best drainage for an appendix case is the posterior drain just above the iliac crest. If we drain the wound anteriorly we are very liable to get a hernia appearing subsequently through our scar.

The operation of appendicectomy may prove the simplest we can possibly be called upon to perform, but if adhesions be present it may prove a most difficult and tedious operation, but, whatever the difficulties we encounter, it is our duty to our patient never to be dismayed, but to remove the offending organ, if we can possibly do so without risking the life of our patient. A tedious operation and a life saved is more creditable to a surgeon than an abandoned operation, resulting in the death of the patient.

With regard to the operation itself, the most useful incision is that which I have described. An incision in the middle line of the abdomen, or through the right linea semilunaris, would have been useless in Cases 2, 3 and 5.

Splitting the internal oblique in the course of its fibres is useful in straightforward cases, and I have done it on several occasions; but in cases complicated by adhesions it greatly increases the difficulty of the operation.

With regard to the treatment of the appendix, all we need do is to ligature it as near the base as possible, having tied its mesentery, and invert the stump into the wall of the cæcum by means of a purse-string suture. If we adopt this method we are sure of removing the appendix as completely as possible.

It is in cases in which the appendix is incompletely removed that we hear complaints from patients of a "return of the old pain," or attacks of appendicular colic.

## THE NEED FOR LEGISLATION IN REGARD TO ANÆSTHETICS, AND THE LINES UPON WHICH IT SHOULD TAKE PLACE. (a)

By F. W. HEWITT, M.D. CANTAB., ETC.,

Lecturer on Anæsthetics, London Hospital, &c.

THE author submits that the importance of the anæsthetic as a factor in surgery is not sufficiently realised. A large number of deaths under anæsthesia have taken place during recent years and public confidence has been severely shaken. Many of these accidents are undoubtedly attributable to the faulty and inadequate provisions for anæsthesia which often prevail. In order to restore public confidence and to remove the present check to surgical progress certain reforms are urgently needed.

The present unsatisfactory state of the law as regards anæsthetics is dealt with. Any person whatsoever may administer a general or inject a local anæsthetic for a surgical operation. Many fatalities have thus arisen which might have been averted had a medical man been present. Our legislature should be called upon to say who should and who should not administer an anæsthetic. This is the fundamental reform required. When secured, it would unquestionably lead to the permanent establishment of the two other reforms which are needed—viz., the more thorough instruction in anæsthetics of all medical students and the better equipment, in *personnel* and otherwise, of the anæsthetic departments of our hospitals. The

question of legislation in regard to anæsthetics is part of the greater question of the suppression of unqualified practice in general, and the legislation here proposed would form a fitting instalment towards a more comprehensive measure. The chief difficulty lies in deciding where the line should be drawn—in other words in defining who should, and who should not administer anæsthetics. It is contended that no *general* anæsthetic should be administered except by a registered medical practitioner. It is also contended that this would in no way interfere with the interests of registered dentists. The new system would tend rather to raise their professional status and to free them from the present unsatisfactory and dangerous practice of single-handed anæsthetising and operating. It would, moreover, strike a decisive blow at quack dental practice, and so greatly benefit the dental profession.

The author has instituted inquiries as to the conditions of dental practice in the following towns, viz. :—

Aberdeen.	Ipswich.
Aberystwyth.	King's Lynn.
Armagh.	Kingstown.
Ballymena.	Leigh (Lancs.).
Bath.	Limerick.
Bedford.	Llandrindod Wells.
Belper.	Ludlow.
Boston.	Newton Abbot.
Bournemouth.	Nottingham.
Brighton.	Oxford.
Bristol.	Paignton.
Brixham.	Penarth.
Cardiff.	Reading.
Carnarvon.	Ryde.
Cheltenham.	Selby.
Chepstow.	Sleaford.
Deal.	Swansea.
Dumfries.	Taunton.
Exeter.	Teignmouth.
Falmouth.	Torquay.
Galway.	Tralee.
Gateshead.	Trowbridge.
Gloucester.	Truro.
Greenock.	Wick.

The following are the results obtained :—

TABLE showing conditions of registered dental practice in 48 towns scattered throughout the United Kingdom, the population of which varies between 342,388 and 1,827.

A	
Total population of the 48 towns	2,138,130
B	
Total number of registered dentists (excluding registered or qualified assistants) in practice in the 48 towns...	482
C	
Ratio between registered dentists in practice and population...	1 registered dentist to every 4,435 persons.
D	
Total number of registered dentists in practice by themselves in the 48 towns ...	352
E	
Percentage-ratio of dentists of Group D to those of Group B ...	73 per cent.
F	
Total number of registered dentists in partnership in the 48 towns ...	99

<b>G</b>		
Percentage-ratio of dentists of Group F	20.5	
to those of Group B	...	per cent.
<b>H</b>		
Total number of registered dentists in		
the 48 towns practising with regis-		
tered or qualified assistants (ex-		
cluding the latter)	...	31
<b>I</b>		
Percentage ratio between dentists of	6.5	
Group H and those of Group B...		per cent.

These statistics show that the great majority of provincial dentists have neither partners nor registered assistants, so that unless they call in medical men to administer their anæsthetics they must either themselves administer them and then operate, or obtain the assistance of persons who are quite unfit to take upon themselves such responsibilities. As it is now generally conceded (see evidence before Departmental Committee) that single-handed anæsthetising and operating is reprehensible, and that the employment of unqualified assistants, domestic servants, etc., as anæsthetists, is also to be deprecated, the only course left is that for which an appeal is here made—the administration of general anæsthetics by medical men.

Since the "General Anæsthetics Bill," now before the Departmental Committee at the Home Office, was drafted it has been found possible to modify it so as to include local (injected) anæsthetics. The following is a copy of the Bill thus modified:—

#### MEMORANDUM.

The objects of this Bill is to protect the public, as far as possible, against deaths arising directly or indirectly from the action of anæsthetics—a class of drugs or substances employed for producing either generalised or localised insensibility during surgical, medical, obstetrical, or dental operations, acts or procedures.

The three following facts indicate the need for this legislative protection:—

1. Anæsthetics are for the most part powerful poisons.
2. They are constantly being used upon a vast and increasing scale throughout the country.
3. A considerable and increasing number of fatalities are annually taking place in connection with their administration.

The promoters of the present Bill are of opinion that the solution of the problem of reducing the number of deaths wholly or partly referable to anæsthetics is to be found in a careful study of the circumstances and symptoms which have attended the deaths hitherto recorded. Such a study seems to them to indicate that anæsthetics, when employed for the above-named purposes, should be administered only by certain persons. This Bill therefore proposes to make it a penal offence for any person other than the persons herein specified to administer for the purposes above mentioned either any general anæsthetic or any local anæsthetic by the means described.

#### ANÆSTHETICS ACT, 1912.

An Act to regulate the administration and employment of anæsthetics.

Be it enacted by the King's Most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal and Commons in the Present Parliament assembled and by the authority of the same as follows:—

1. Any person other than a legally qualified

medical practitioner registered under the Medical Acts who shall wilfully administer or cause to be administered to any other person by inhalation or otherwise any drug or substance, whether solid, liquid, vaporous or gaseous, and whether pure or mixed with any other drug or substance, with the object of producing a state of unconsciousness during any surgical, medical, obstetrical or dental operation, act or procedure, or during childbirth, shall be liable on conviction before a Court of Summary Jurisdiction for such offence to a penalty not exceeding £10, and in the case of a second or subsequent conviction to a penalty not exceeding £20, provided always that a person shall not be liable to a penalty under this Section if in conducting such administration he was acting under the immediate direction and supervision of a legally qualified medical practitioner, or if the circumstances attending the administration were such that he had reasonable grounds for believing, and did believe, that the delay which would have arisen in obtaining the services of a legally qualified medical practitioner would have endangered life, or if having been registered under the Dentists' Act, 1878, before the passing of the present Act he conducted such administration for a dental operation, act or procedure.

2. Any person other than a legally qualified medical practitioner registered under the Medical Acts who shall inject, insert or introduce, or cause to be injected, inserted or introduced into any tissue or tissues of the body of any other person through a puncture, incision or other breach of surface, any drug, medicament or substance, whether solid or liquid, and whether pure or mixed with any other drug, medicament or substance, with the object of producing a state of localised insensibility to pain without unconsciousness during any surgical, medical, obstetrical or dental operation, act or procedure, or during childbirth, shall be liable on conviction before a Court of Summary Jurisdiction to a penalty not exceeding £10 and in the event of a second or subsequent conviction to a penalty not exceeding £20, provided always that a person shall not be liable to a penalty under this Section if in attempting to produce, or in producing, such localised insensibility he was acting under the immediate direction and supervision of a legally qualified medical practitioner, or if being registered under the Dentists' Act, 1878, he attempted to produce, or did produce, such localised insensibility for the performance of a dental operation, act or procedure, or if, being a *bonâ-fide* student in dental surgery or dentistry, and acting under the immediate direction and supervision of a person registered under the Dentists' Act, 1878, he attempted to produce, or did produce, such localised insensibility for the performance of a dental operation, act, or procedure.

3. The expression "Court of Summary Jurisdiction" in this Act shall have the same meaning as in Sub-Section 11 of Section 13 of the Interpretation Act, 1899. In Scotland it shall mean any Justice of the Peace, and also the Sheriff. The expression "the Medical Acts" shall mean the Medical Act, 1858, any Acts amending the same passed before the passing of this Act.

4. This Act may be cited as the Anæsthetics Act, 1912.

LAST week it was stated at a meeting of the Stepney Council that two or more cases of small-pox had occurred in the borough of Stepney. The newly infected persons were the sister and brother-in-law of the man Gaffney, who was discovered with the disease in Whitechapel, and afterwards died. They were removed to the small-pox shelter, and were not allowed to come in contact with other persons.

## QUACKS, FALSE REMEDIES, AND THE PUBLIC HEALTH.

By DAVID WALSH, M.D.ED.,

Senior Physician, Western Skin Hospital; Physician, Kensington and Fulham General Hospitals.

### PART V.

#### AN AMERICAN BOOK ON QUACKS AND QUACKERY. (a)

IN the United States the question of secret remedies has been taken up with vigour. The American Medical Association recognises the good faith of some proprietary medicines. In February, 1905, a Council on Pharmacy and Chemistry was formed to investigate the subject. Numerous analyses of many secret remedies were made, and reports published dealing with claims to cure, therapeutic value, cost, composition, and other pertinent matters. These reports have been reprinted in a small octavo volume, of rather under three hundred pages. They form a valuable mass of evidence.

The American book deals with a number of nostrums not included in "Secret Remedies." It treats everything with unsparing frankness. Those who require any information as to the Viavi remedies for female troubles will find a fairly full notice in its pages. That particular method, with its various medicaments, appears to have originated in California, and thence, after the fashion of such things, to have spread to other quarters of the globe. In the United Kingdom Viavi is lectured upon to women, and advertised in some of the larger towns.

#### THE INLAND REVENUE.

One of the cruelties of the traffic in secret medicines is the use of alcohol. In this way it may lead man, woman, or child to acquire a drug habit, and at the same time inflict all kinds of damage to brain, kidneys, liver, and other internal organs. A more striking example of callous contempt of right-mindedness it would be hard to find than that afforded by the sale of whisky to teetotallers as "tonics" and of strong dilutions of ardent spirit to drunkards under the guise of "drink cures." A common abuse is that of sham "tonics" composed of Taragona port or other wine, compounded with various meat essences, extractives, and so on. The Inland Revenue might interfere in all alcoholic secret medicines with considerable effect, inasmuch as their action would reveal the true nature of the wrong that has been perpetrated not only upon the public, but also against the national revenue. In Canada, where effective steps have been taken against both abuses, the subject of patent medicines has been investigated in the laboratory of the Inland Revenue Department, Ottawa. Mr. Thomas Macfarlane, Chief Analyst, in the course of a report (b) to the Deputy Minister of Inland Revenue, January 9th, 1906, Bulletin 3, says of "Peruna":—"From the small percentage of total solids contained in this article, less than is found in ordinary rye or Scotch whisky, it does not appear to belong to the class of patent medicine. The quality of alcohol found in it (40 per cent. proof spirit) is considerably higher than the strongest port wine, and about two-thirds that of the ordinary grade of whisky. It becomes a question whether it could be legally sold by druggists without a liquor licence. In the *New Hampshire Sanitary Bulletin* of the present month it is stated that an order has been issued by the Commissioner of Internal Revenue, Treasury Department of the United States, requiring dealers in certain patent medicines to pay a revenue tax as liquor dealers." A list of proprietary preparations follows, and of these Mr. Macfarlane says:—"These preparations contain so small an amount, if any, of effective drugs or medicines, and so large an amount of alcohol, as to make their use as intoxicants not uncommon."

Here, then, we find in an existing organisation a

(a) "The Propaganda for Reform in Proprietary Medicines." Reprinted from *The Journal of the American Medical Association*. New York. Fifth Edition. September, 1908.

(b) "Australian Report," p. 109.

powerful means of attacking one of the deadliest and most insidious of secret remedies. Armed with an analysis showing the alcoholic and other ingredients (or lack of ingredients) of a remedy of this kind, it should not be a matter of any great difficulty to induce some member of Parliament interested in temperance questions to ask a question in the House about the incriminated preparation, and in that way to reveal its true nature not only to the public, but also to the Inland Revenue authorities.

#### THE FOOD AND DRUGS ADULTERATION ACT.

IN some instances where it can be shown that the vendors of patent medicines have failed to use the drugs that are named in their advertisements, they would probably lay themselves open to prosecution under the Food and Drugs Act. In the above-quoted Bulletin No. 113 of Mr. Macfarlane, he writes of "Ozone":—"Since this article contains a substance whose properties are the opposite of those indicated by the name, its sale would appear to be illegal under Section 2 of the Adulteration Act, according to which a drug shall be deemed to be adulterated 'if its strength, quality, or purity falls below or differs from the professed standard under which it is sold or offered for sale.'"

That something can be done, however, under the British Food and Drugs Act has been shown by Dr. Hope, the Medical Officer of Health for Liverpool. He obtained a conviction in the case of a patent medicine vendor who sold a nostrum as a specific cure for liver complaints. This so-called remedy he showed to consist of an acidified solution of glycerine worthless for the purpose mentioned, therefore sold to the detriment of the purchaser. His successful prosecution under the Food and Drugs Act suggests that Medical Officers of Health might exercise a great amount of control generally over the trade in secret remedies. Dr. J. C. McWalter (a) insists on the importance of Dr. Hope's precedent, which, coupled with the published analyses of the British Medical Association, should induce local Councils to prosecute persons selling worthless articles as cures for diseases. Then medical officers of health could testify to the worthlessness of the preparations and the purpose for which they were sold.

Dr. McWalter holds that the solution of the quack medicine problem is to be found in compelling the makers of nostrums to set forth the ingredients on the label. His remarks on the attitude of the British Government, which last year received some £340,000 from the Inland Revenue stamps upon patent medicines, put the case with strong and vigorous rhetoric.

"The concurrence of the Government (b) in this traffic," he writes, "has become a national scandal. No other reputable legislature on earth has consented to take from quack medicine vendors what may be described as the 'wages of sin.' There is, indeed, a small tax in the United States on proprietary articles, but as their composition must be set forth on the label, the money may be considered as comparatively untainted. The Government of France tolerates no quack remedies—home or foreign; the ingredients must be made known to the public. The German Government have even a stricter rule. Were our flourishing quack medicine makers, who take over £2,000,000 per annum from the sick and ignorant, and pay £340,000 to our Government, to attempt to carry on their calling under like conditions in Italy, or even Russia, the police and the gaol await them."

#### THE CHILDREN ACT, 1908.

Dr. A. G. Bateman has drawn attention to the fact that it is possible to proceed indirectly against irregular practitioners who have treated children under the age of 16 years. The Children Act, 1908, Section 12, renders it a misdemeanour for a parent or other person legally liable to maintain a child (c) or young person (d) who shall be deemed to have

(a) "How to deal with the Quack Medicine Traffic." By J. C. McWalter, M.A., M.D. *Medical Press and Circular*, September 22nd, 1909.

(b) *Loc. cit.*, p. 318.

(c) "Child" defined for purposes of Act as under 14 years.

(d) "Young person," 14 to 16 years.

neglected him in a manner likely to cause injury to his health if he fails to provide adequate food, clothing, medical aid, or lodging for the child or young person. The misdemeanour is punishable under the Act on conviction on indictment to a fine not exceeding £100 and imprisonment up to two years, or on summary conviction to a fine not exceeding £25, or six months' imprisonment. Should it be shown that the parent or guardian is directly or indirectly interested in money accruing from the death of the child or young person, the punishment on conviction is much heavier. Again, should the child or young person die, the parent or other guardian is open to a prosecution for manslaughter.

The bearing of this upon quacks and quackery is clear. Any parent or guardian of any child or young person is liable to smart punishment if convicted for having failed to provide adequate medical aid, demanded by Section 12 of the Act. It is hardly conceivable that any magistrate would regard the advice of an unqualified person as falling under that head. Nor is it likely that the prescription of a chemist, despite his knowledge of drugs, would fall within the definition of "adequate medical aid." Then comes the further point that any person giving unqualified services in such a case would become an accessory to a misdemeanour or a felony, and therefore open to prosecution. In this way it would be possible to prosecute the whole tribe of bonesetters, herbalists, bogus oculists, and others—indeed, of all quacks incautious enough to treat any person under 16 years of age. It may sound somewhat harsh to mention in this connection chemists, who form a skilled and honourable class of men. Nevertheless, it is evident that if, by reason of good nature or inadvertence, a chemist were to prescribe certain physic for the use of a young person, he might find himself involved in extremely unpleasant consequences.

Another strong point in the Children Act is the provision in Clause 6 that in the case of any person who has taken charge of an infant he is to give notice in writing of the death within 48 hours. Unless a certificate signed by a duly qualified medical practitioner is forthcoming, the coroner is required to hold an inquest upon the body, unless satisfied that there is no ground for such an inquiry. A proper observance of this clause would probably render parents and guardians less likely to resort to quacks and quack medicines for their ailing children. This section should be known by all resident medical officers at hospitals and other medical charities. It is a common practice to bring babies and children who have been neglected or treated with quack remedies to a hospital once or twice, and then, in case of death, to apply for a certificate. A rigid rule should be observed in all medical charities that no death certificate should be signed in the case of any patient who has not been under treatment for at least a week. A rule of that kind is strictly kept by almost all medical practitioners. It is obvious that the bringing of a large number of cases of infant deaths under the notice of the coroners would enable the latter to acquire a mass of accurate information as to illegal medical practitioners and the effects of secret remedies administered to infants. By keeping in touch with the police, coroners might do a great deal under the Children Act towards the suppression of quacks and quackery.

#### THE PHARMACEUTICAL SOCIETY.

The Pharmaceutical Society was established in 1841. There have been five Pharmacy Acts between 1852 and 1908 which have given them powers of examining and registering. The functions which concern the present inquiry are the Society's right (a) to institute proceedings against sellers of poisons, and (b) through His Majesty's Order in Council to vary poisons schedule.

(a) The right of the Pharmaceutical Society to prosecute sellers of poisons apparently furnishes a powerful weapon of attack upon patent medicine vendors who use certain recognised poisons in their proprietary medicines. The Society can now gain authoritative information as to many of these preparations from the books published by the British Medical and the American Medical Associations ("Secret Remedies"

and "Propaganda for Reform" respectively), and from the "Australian Report."

(b) As regards the poisons schedule, would it be feasible for the Pharmaceutical Society to extend—or take steps to extend—the poisons schedule so as to add certain drugs to the list so far as patent and proprietary medicines are concerned? If it be shown, for instance, that colchicine is sold in certain pills to "correct" female troubles, and that its action as a cumulative poison is highly dangerous, could not the sale of that drug in that form be made the subject of prosecution? Again, calomel is a dangerous poison in the case of children, and is extensively sold in the form of "teething powders." Would it not be possible to schedule calomel as a poison in secret remedies, and proceed against those who sell it hereafter?

If this principle be once established, its extension to acetanilide, opium, morphia, and many other poisons would aim a deadly blow at the most injurious portion of the quack medicine trade.

#### THE BRITISH MEDICAL ASSOCIATION.

The most powerful organisation hitherto created amongst medical men is that of the British Medical Association. During the last few years the evolution of that body has been proceeding at a rapid pace. It is needless to dwell upon the many ways in which they might help the campaign against quacks and quackery. Such steps as advisory representations to the General Medical Council, pressure upon corporations to exercise their powers in particular cases, appeals to Government for the amendment of defective Acts, and the like, are sufficiently obvious. Coming from the representative organisation of the majority of the medical profession, their opinions could not fail to carry weight with any official body.

It would be, perhaps, possible for the Association to co-operate with the Society of Apothecaries in the prosecution of unqualified practitioners, and to defray a part of the cost of such proceedings out of the funds of the Association.

#### THE SOCIETY OF APOTHECARIES OF LONDON.

The Society of Apothecaries of London dates, as a licensing body, from James I., in the year 1617. The original Charter gave them the power to "remove or prohibit" persons practising unsatisfactorily as apothecaries without their licence. Under the Apothecaries Act, 1815, they can and do from time to time prosecute unqualified persons who infringe the privileges of the apothecary. Bonesetters appear to be outside the Society's jurisdiction. Herbalists have sometimes met their prosecution with a defence already mentioned, raised under a statute of Henry VIII., not yet formally repealed, which granted to them certain privileges with regard to sundry specified diseases. It would be an advantage to the public were the General Medical Council to carry to appeal, should occasion arise, the question whether the Act of Henry VIII. is still operative or otherwise.

The statute above alluded to, is thus spoken of in the first "Medical Directory," (a) published in 1845:—"By Statute 34 and 35, Henry VIII., c. 8, unlicensed persons may use and minister on and to any outward sore, income wound, apostumations, outward swelling or disease, any herb or herbs, ointments, baths, pultures or emplaisters, according to their cunning, experience or knowledge in any of the diseases sores and maladies aforesaid, and to all other like to the same, in drinks for the stone, strangury, or agues, without suit vexation trouble penalty or loss of their goods, the foresaid statute in the foresaid 30th yeare of the King's most gracious reign or any other Act notwithstanding."

With respect to this statute, Lord Chief Baron Comyns says (in his "Digest title Physician D.") that it "enables only to make application to external sores," etc., not internal; and in Le Colledge de Physicians' case, Littleton's Reports 349, Lord Chief Justice

(a) "The New Directory of Great Britain and Ireland for 1845," Published at Medical Directory Office, 272 Strand, Oliver and Boyd Edinburgh; Fannin and Co., Dublin; and by all booksellers.

Richardson, in delivering the judgment of the Court of Common Pleas, says that "this statute reaches neither in word, nor in intent and meaning to give liberty to any person that practises or exercises for lucre or profit, so that this statute excludes all those who take any money or gain."

This last-mentioned ruling seems to be of importance in view of the defence set up by herbalists and others. It apparently shows that if any money is paid to the unqualified person he cannot avail himself of the statutory right conferred by 34 and 35, Henry VIII.

The Apothecaries Act appears to give ample powers for the suppression of quacks. Presumably, also, it is able to put a stop to the sale of medicines for the cure of disease by unauthorised persons. The costs of prosecutions no doubt usually falls upon the Society, which can hardly be expected to undertake wholesale proceedings of the kind. Were the State to find the money for legal process under the Apothecaries Act, there would be little need of fresh legislation.

The writer has been reminded by a legal friend that recent legislation has rendered it possible for magistrates to give costs in cases of this kind. This fact may encourage the Society to increase the number of prosecutions.

#### TREASURY PROSECUTIONS.

The "Australian Report" (p. 365) comments upon the "First and only prosecution of the British Treasury," that is to say, of a quack. On September 21st, 1906, William Henry Hawkins, 62, and his son were charged on a Treasury warrant with conspiring by false pretences to obtain money and valuable securities from such of His Majesty's subjects as should thereafter purchase from them certain powders. Their circulars included a biography, written by the elder Hawkins, of the Rev. Joseph Hook, telling how he discovered the wonderful powers of the medicine known as "Corassa Compound" from a priest in South America. The compound was said to consist of four drugs: "Corassa abinus, selarmo umbertifera, alkernes edifolia, and karsadoc herbalis." This medicine was said to cure forty-seven diseases. Other remedies, discovered by other clergymen, were circularised under the name of the Rev. Mr. Stone. Analysis showed the powders to consist of a mixture of bicarbonate of soda and bromide of potassium. The trade cost of twenty-five powders was about one penny. That number of powders was sent by accused at a charge of 18s. 6d., and it was stated that a chemist would charge 28s. for making up these powders. The prosecution against the younger Hawkins was withdrawn, but the father was found guilty.

The judge, in passing sentence of three months' imprisonment with hard labour, said that he looked on it as a sort of test case, and he wished the Treasury every success in taking up cases of that kind. A great and good work would be done by stopping the sale of quack medicines.

The Australian Commissioner makes some caustic comments on the result of this trial. "Can anyone claim," he asks, "that the judicial perception of right really accords with the desires of the British people? Four years' for stealing a skirt, two years' for snatching a hand-bag, seven years' for embezzlement, five years' for stealing ducks, as against three months' for issuing—uttering—200 to 500 actual forgeries a day, and carrying on the practices for ten years at least. Hawkins made 'considerable sums of money' by proven fraud against the lives and health of the public, especially against persons suffering from contagious sexual diseases, so that wide personal and racial damage was done. Three months' confinement for these multitudinous infamies! No wonder, when such is the proper punishment, according to the judicial estimate, that this was the first and only prosecution by the Treasury."

As a matter of fact, the prosecution of Hawkins had been demanded by the *Lancet* ten years before his actual trial. What can be the candid feelings of newspaper editors who for all that period inserted the felonious advertisements whereby this impersonator of clergymen was enabled to defraud the public with his worthless nostrum?

From what has been said, it is clear that there are in existence many ways in which both false practitioners and false and secret remedies may be checked and controlled. It is to be hoped that the General Medical Council, faced with the failure of the penal section of the Medical Act of 1858, will ascertain the exact legal position both of the Council and of other bodies with regard to their powers against quacks and quackery.

#### SUMMARY AND CONCLUSION AS TO EXISTING METHODS OF CONTROL.

The real want is a Public Prosecutor or a Department that would put into force some of the many existing laws that can be brought to bear upon the unqualified practice of medicine and the sale of injurious secret remedies. Were the police to take up zealously the prosecution of offenders under the Children, the Death Certification, the Adulteration, and other Acts, and generally of obtaining money under false pretences, a great deal of good would be effected. The chief defect in the application of various existing laws to suppress the evil of quackery lies in the want of a zealous prosecuting authority and of a means of defraying the cost of prosecution. Were the legislature bent on suppressing quacks, as they suppress or punish burglars, they would find plenty of ways and means in the law as it stands. For instance, by paying the costs of prosecutions under the Apothecaries Act, it is possible that the State might practically put an end to irregular medical practice. At the same time, their hands might be greatly strengthened by certain legal and administrative reforms, which suggestions will be dealt with in our next and concluding section.

#### HOW TO DEAL WITH QUACKS AND SECRET REMEDIES.

##### RECOMMENDATIONS.

##### PUBLICATION OF FORMULA.

The stronghold of the secret medicine vendor is secrecy, and anything that does away with that condition will deal him a death blow.

The publication of the formula of the contents of every secret remedy, its attachment to every package or bottle, and its appearance in every advertisement, is an obvious step on the part of any legislature desirous of checking the evil.

Publication is the rule in Germany and other countries, and has been found to work well enough. It would not damage the respectable proprietary manufacturer, who already in many cases publishes the full formula of his preparation. He is content to copyright his title and to look for his reward in the sale of a good article with the approval of the medical profession.

##### ABOLITION OF THE PATENT MEDICINE TAX.

The patent medicine stamp should be abolished. In the eyes of ignorant persons it undoubtedly suggests a guarantee from the Government as to the good qualities of the article to which it is attached. By accepting a money payment the Government are to a great extent hampered in prosecution when fraud is revealed. Nay, it is a fact that the Government stamp is still fixed upon articles that have been publicly proclaimed to be fraudulent by His Majesty's Judges in open Court. The Australian Report has exposed a mass of fraud, chicanery, damage to the public health, and criminal practices in connection with patent medicines. Yet the British Government are being paid for their protection to not a few of the false remedies thus exposed. The British revenue benefits to the extent of a few hundred thousand pounds (a) yearly from patent medicine stamps. As a matter of fact, the money comes from the pockets of the deluded customers, so that the State is actually making money out of this nefarious trade. So accustomed have the Government grown to this source of revenue that we may be thankful that there has been no attempt to

(a) Revenue from patent medicine stamps £268,000 in 1907: £334,000 in 1908.

extend the tax during the recent deficits in the national Budget. The attitude of the average statesman towards the patent medicine stamp duty may be gauged from the answer given by Mr. Herbert Gladstone on September 16th, 1909, to Captain Craig. In his answer the Home Secretary practically promised the appointment of a Select Committee in the following session to inquire into the sale of patent medicines. This important announcement was made in response to Captain Craig's question: "Whether the Home Secretary would consider the advisability of issuing regulations making it compulsory on all manufacturers of medicines liable to patent medicine duty to print on the label on the bottle or other vessel in which such article is sold the full ingredients of such bottles or vessels, as well as the diseases they purport to cure; whether he would consider the advisability of increasing the size of the lettering of the Government stamp as a further precaution against ignorant people believing that the contents are guaranteed by Government." In his reply Mr. Herbert Gladstone said "he was in communication with the Privy Council with reference to the first part of the question, and he was disposed to think the matter of sufficient importance to require an inquiry by a Select Committee next session. New designs for stamps and labels had recently been adopted, and were being prepared, which would clearly indicate that the stamp did not imply a Government guarantee."

Here we have a leading statesman acknowledging in the Commons that the State is ashamed of the wares from which this mean and paltry duty is taken.

From an economic point of view the paltry sum of money raised for the revenue from the patent medicine duty must represent an enormous trade in false remedies that in the long run inflict incalculable damage upon the health and the lives of the nation.

The probability is that the cost to the public of stamped nostrums must be somewhere between two and a half and three and a half millions yearly.

The abolition of the patent medicine duty is one of the first duties of a Chancellor of the Exchequer who has the national welfare at heart, and who wishes to draw his revenue from sources that are wholesome and untainted.

#### A ROYAL COMMISSION.

One of the best methods of gaining a thorough knowledge of the facts of the case and of educating the public thereon is undoubtedly by way of Royal Commission, with full power of summoning witnesses and of otherwise obtaining information. That plan has been adopted with extraordinary success by the Commonwealth of Australia, which is flooded with quacks and quackery of the same pernicious kind that devastates the British Isles. Recognising the advantages of this step, the General Medical Council have lately petitioned the Privy Council in favour of a Royal Commission upon irregular medical practice. Such an inquiry, however, would be of little use were it to exclude secret remedies, which, in point of fact, constitute one of the most deadly and injurious forms of false medical practice. That fact was fully realised by the sturdy logic of King Henry VIII., whose charter created a College of duly qualified medical men on the one hand, while on the other he conferred on that body the duty of suppressing false practices and false drugs by powers of a summary kind. A Royal Commission, then, if it is to fulfil its functions adequately, must investigate the sale of secret remedies as a part of the larger question of irregular medical practice.

#### HOW TO SOLVE THE PROBLEM BY EXISTING LAWS.

Since the stalwart days of Henry VIII. there has been little or no efficient legislation against quacks and quackery, save a pious affirmation of the powers of the Royal College of Physicians of London in various reigns up to the year 1860. The restraining powers have been in existence, as regards London, for nearly 400 years, but have been poorly applied. The Medical Act, 1858, which, under Section XL., should have extended similar penal powers to the whole Kingdom, has proved a failure, not so much on account of its inherent weakness, as of the interpretation put upon the Section by magistrates and judges. As

regards this particular kind of legislation, indeed, there appears to be a peculiar leniency in legal administration, and on that account alone it would be wise to make use as far as possible of existing laws, short of the attempt to secure fresh legislation. If, as sometimes contended, the penal powers of the London College of Physicians of London, or of any other bodies, were superseded by the creation of the General Medical Council in 1858, it becomes all the more incumbent upon the latter body to take steps to render those powers effectual. Fortunately, there are many legal methods by which quacks and quackery may be directly and indirectly attacked. These methods have, for the most part, been already discussed, so that there will be little need in conclusion to do more than append a list of the author's recommendations with a note here and there of important details.

#### RECOMMENDATIONS.

##### TO INSTITUTE

1. A Royal Commission upon unqualified medical practice, including secret cures and remedies.

##### TO ENFORCE

2. The Children Act, especially as regards the duty of obtaining adequate medical aid for infants and young persons.

3. The statutory duties of the Royal College of Physicians of London as regards London and a compass of seven miles round, if it can be shown that they are still in existence, as regards false medical practice and false drugs and remedies.

4. The administration of Excise and Inland Revenue as regards patent and proprietary medicines.

5. The various powers of coroners, police, registrars, and Public Prosecutor with regard to the evil practices of quacks and the injurious results of secret cures and remedies brought under their official notice.

6. The penal powers of the Society of Apothecaries of London against unqualified practice.

7. The powers of the Pharmaceutical Society against unqualified pharmacists and the scheduling of poisons sold in proprietary and patent medicines.

##### TO ABOLISH

8. The patent medicine stamp duty.

##### TO AMEND

9. The Poisons Act, so as to extend the poison schedule, and apply a prominent poison label to all secret remedies containing one or more of the drugs so scheduled. If deemed advisable, also to create a special extension of the poison schedule, to be applied solely to proprietary and patent remedies.

Further, to forbid absolutely the sale in secret remedies of certain potent drugs, which should never be prescribed except under skilled medical authority and supervision. Also to provide that the word "poison" affixed to any label shall be in conspicuous red letters.

10. The Food and Drugs Acts to be amended so that patent medicines are brought explicitly within the provisions directing that a vendor shall supply materials dealt with by the Act of the nature, quality, and substance demanded by the purchaser, and proposed to be sold by the vendor.

11. The Medical Act, 1858. The Act might be greatly strengthened so far as the suppression of quacks and quackery is directly and indirectly concerned:—

(a) By increasing the number of directly-elected representatives of the medical profession on the General Medical Council.

(b) By causing the nominees of the various universities, colleges, and other medical corporations to be in all cases elected by the holders of their respective degrees and qualifications.

(c) By amending Section XL. on the general lines that the public should be protected against unqualified medical practice not less efficiently than they are against unqualified dental, veterinary or legal practice, and more particularly by omitting the condition that in order to secure conviction the accused person must be shown to have "wilfully and falsely" pretended to be or have taken the name or title of a physician, etc.: in other words, to constitute medical practice by an

unqualified person a punishable offence in itself, apart from any personal knowledge that he is committing an offence.

(d) By the substitution or addition of the principle as regards Section XL. that it is illegal for an unqualified person to exercise or discharge any act essentially appertaining to qualified medical practice.

(e) By granting summary powers to recover fines and costs upon conviction under Section XL.

12. The Apothecaries Act, 1815, so as to confer summary powers of recovering fines and costs from offenders upon conviction.

It is to be hoped that the Legislature will recognise and put a stop to the evil that is wrought upon the community by unqualified medical practice. The statesman who undertakes to sweep out this Augean stable will find himself faced with no light task. Owing to the attitude of the newspapers, he would find that the case can be adequately established only by means of a Royal Commission, whereon the main body of the medical profession was duly represented. On the other hand he would probably recognise that, by a wise amendment and consolidation of existing laws, Parliament would avoid the necessity of fresh legislation to put an end to the evils inflicted upon the nation by false medical practice and by the sale of secret remedies.

## CLINICAL RECORDS.

### A CASE OF ACCIDENTAL VACCINATION— WITH PHOTOGRAPH OF THE PATIENT.

By RANDAL HERLEY, B.A., Roy. Univ.,  
IRELAND, L.R.C.S., L.R.C.P., EDIN.,  
House Surgeon, General Infirmary, Dewsbury.

MRS. S., æt. 22, was admitted on June 6th, 1909, suffering from swelling of the left upper eyelid and sores on the right nipple. She had never been vaccinated.

On May 13th, 1907, the patient was delivered of a child, which she suckled until May 9th, 1909. The child was vaccinated on May 19th. On

June 1st, Mrs. S. noticed some sores on her nipple; she spoke to her mother about them, who remarked, "they are very like vaccination marks." On June 2nd the left upper eyelid began to swell; the patient complained of pain, and was unable to open the eye. The left side of the face was swollen.

On admission her temperature was 101, and pulse 90. There were three typical vaccine pocks on the right nipple; the glands in the right axilla were enlarged and tender. There was considerable swelling of the eyelid and chemosis. On the margin and outer surface of the eyelid, close to the inner canthus, there was an ulcer with a greyish floor and hard border. The cornea was clear. The eye was treated with boric acid lotion and fomentations. Mrs. S. was made an out-patient on June 17th. The ulceration was confined to the eyelid. I saw this patient quite recently, and beyond a slight thickening of the skin and loss of the eyelashes at the affected part, very little can be seen.

## OPERATING THEATRES.

### ROYAL FREE HOSPITAL.

PISTOL SHOT WOUND OF THE ABDOMEN.—MR. WILLMOTT EVANS operated on a woman, æt. 54, who had been admitted with a bullet wound of the abdomen. She was walking past a public-house about two hours before the operation, when the door suddenly opened and a man ran out. He was followed closely by another, who fired with a revolver at the first man. The patient was between the two, and received the bullet in the abdomen. She was at once brought to the hospital, suffering from a little shock and more fright. The bullet wound was found on the left side of the abdomen, above a line drawn vertically upwards from the middle of Poupart's ligament and on a level with an inch above the umbilicus. A second bullet wound was found at an almost corresponding position on the right side. She was at once admitted, and as it was impossible to tell whether a viscus had been injured or not by the bullet in its transit through the abdomen, it was resolved to explore. The abdomen having been cleansed, and the patient having been anaesthetised, it was opened in the middle line above and below the umbilicus, and the bowels examined. Immediately behind the abdominal wall, and on a level with the bullet wounds, lay the transverse colon, and on its anterior surface near the middle was a slight longitudinal groove just perforating the peritoneum, but hardly injuring the muscular coat. Two Lembert's stitches were put in the peritoneum of the bowel so as to close in the wound. The bowel was then replaced. No injury of any other abdominal viscus was discovered. The tracks of the bullet were examined; no bleeding was present. Their internal openings were closed; no stitches were placed in the bullet wounds of the skin, as they were so minute; the abdominal wound was sutured and dressed, and the patient put back to bed.

Mr. Evans said that not many years had elapsed since a surgeon was averse to opening the abdomen in cases of bullet wounds unless he felt sure that some viscus had been injured, and this practice extended to the period after the introduction of antiseptic surgery; it was true that a certain number of bullet wounds of the abdomen heal and the patients recover, even though no operation is done, though it was certain that the bullet had entered the abdominal cavity, especially when the projectile has been a small bore bullet of a modern rifle or revolver. The proportion of recoveries is, however, small, and it is nowadays always advisable to explore in cases of bullet wounds of the abdomen, unless it is absolutely certain that the bullet has not entered the abdominal cavity, and on this point it is very difficult to be certain except in

cases where the wound is very superficial. To account for the recoveries in cases where no operation has been performed it has been suggested that a small bullet may perforate a piece of bowel and yet through contraction of the opening or the plugging of it by eversion of mucous membrane no extravasation may occur, and no peritonitis may follow. Whether this ingenious explanation is correct or not, it would be absurd to trust to the possibility of such a thing happening, and there can be no doubt that the safest plan is, as he had before mentioned, to explore all bullet wounds of the abdomen. In the present case the prominence of the abdomen made it practically certain that the bullet, even in passing straight from one aperture to the other, had entered the abdominal cavity; therefore, it was thought not advisable even to probe the wound. The two openings were very similar in appearance, but it was clear which was the aperture of entrance and which of exit, for the aperture of entrance had bruised edges, and it was slightly smaller than the aperture of exit, the edges of which were slightly everted, and the testimony of the patient corroborated that she had been wounded on the left side.

The wound of the transverse colon was about as slight as it possibly could be, and in all probability it would have healed completely, even if no operation had been performed, though it is not unlikely that the surface which had been denuded of its peritoneum would have become adherent to the abdominal wall. Though this case illustrates the fact that a bullet may penetrate and traverse the abdominal cavity without causing any lesion that would prove fatal, yet the operation was fully justified and the risk incurred by it was extremely small.

The patient rapidly recovered, no symptoms appearing at any time. The stitches were removed at the end of ten days, and the patient left the hospital well twenty days after the injury.

## TRANSACTIONS OF SOCIETIES.

### THE ROYAL SOCIETY OF MEDICINE.

#### OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

MEETING HELD THURSDAY, OCTOBER 14TH, 1909.

The Presidential Address was delivered by Dr. MACNAUGHTON-JONES, on  
PAIN ASSOCIATED WITH DISORDERS OF THE FEMALE  
GENERATIVE ORGANS.

Dr. CHAMPNEYS proposed that the thanks of the Section be given to the President for his eloquent address, and that he be asked to allow it to be printed.

Mr. W. D. SPANTON said he seconded the resolution of a vote of thanks to the President with the utmost pleasure. They had listened to a most interesting and suggestive address, the outcome of the ripe experience of Dr. Macnaughton-Jones, graced with that charm which always characterised him. Philosophers have told us there is no such thing as pain, but the President had clearly shown how pain may exist without any tangible physical change, while tissue changes of the gravest character are found where pain has never been felt. Mr. Spanton thought it well that our attention should be directed to these well-known facts in the delightful manner it had been that evening.

Dr. J. CURTIS WEBB, M.B., B.C., read a paper on  
THE USE OF INDICATIONS FOR ELECTRO-THERAPY IN SOME  
GYNÆCOLOGICAL AFFECTIONS.

He remarked that in the treatment of gynæcological affections by electro-therapy different types of currents must be employed to produce different therapeutic effects. A rapidly interrupted induced current produces a sedative effect, and is useful in neuralgic conditions. A current with slow interruptions should be used to tone up relaxed muscle. When bare metallic electrodes are used, they produce their action by ionisation of the metals; local effects are produced, and the result will vary with the valency and composition of the electrodes. Thus a positive zinc electrode amalgamated with mercury has a strong antiseptic action.

Metallic ions are driven in, and the acid radicles of the body fluids being attracted, exercise a cauterising and hæmostatic effect. If the electrode be negative, the basic components of the body fluid are drawn out, producing a solvent or congestive effect. When the electrodes are covered by non-metals, such as wool, there is no ionisation of metallic particles, and so no local effect is produced.

The causes of the metabolic effect brought about by interpolar action were mentioned. The author considered that treatment by static electricity is of great value in certain cases, more especially when a general rather than a local effect is desired. The methods of obtaining and controlling currents, and the various types of electrodes to be used, were next described. In inflammatory diseases of the vagina or vulva, copper or zinc ionisation, used in addition to ordinary methods of treatment, were of great value, and he described a special electrode suitable for these cases. Methods of treating amenorrhœa, scanty menstruation, and dysmenorrhœa, were also mentioned. In inflammatory affections of the uterus brilliant results may be obtained by zinc mercury ionisation, which will probably largely take the place of curettage. Much may be done for simple inflammatory diseases of the tubes and ovaries. As a rule, in these cases a course of abdomino-vaginal applications should precede intra-uterine treatment. Brief notes were given of a series of cases exemplifying these methods of treatment.

In a discussion which followed, Mr. SPANTON expressed his surprise that, in discussing the different forms of electric treatment in gynæcology, no mention had been made of the name of Dr. Apostoli, who certainly deserved credit for being one of its chief pioneers. He (Mr. Spanton) had adopted his treatment in cases of uterine myoma with hæmorrhage, with most excellent results, 20 years ago, but found the method somewhat cumbersome and difficult to carry out in hospital practice, and expensive and tedious in private patients, and these were probably the chief reasons why it has somewhat fallen into disuse.

Dr. AMAND ROUTH said the Section was indebted to Dr. Curtis Webb for bringing before them some electro-therapeutical methods of dealing with gynæcological troubles in women who were averse to "operations," or were for some other reason unable to be dealt with in the usual way. Some years ago, when he had more time, Dr. Routh adopted the methods advocated by Apostoli, and he had found real benefit from the use of the positive intra-uterine pole with a current of 60-120 milliampères in cases of uterine hæmorrhage due to "endometritis" or fibroids or subinvolution. He felt, however, that the time, trouble and expense of the treatment was not justified by the results obtained as compared with those following ordinary methods of treatment. In severe cases of chronic subinvolution and endometritis curettement was preferable, and accomplished much more than mere removal of hypertrophic mucosa as suggested by Dr. Webb, for it led to radical changes in the fibromuscular tissues of the uterus, promoting absorption of inflammatory exudations, lessening bulk, and, generally speaking, restoring the uterus to its normal size and function. Fibroids were only symptomatically cured, and the cure was only permanent when near the menopause. He felt more inclined to believe that the treatment of fibroids by X-rays, as advocated by Albers-Schönberg would cause their atrophy and cure much more effectually than the electrical treatment, even if associated with ionisation, as carried out by Dr. Webb. The fact that Graafian follicles had been proved to disappear from rabbits' ovaries in twelve days, and that sterility had been proved to follow the use of X-rays, and that rapid shrinkage of fibroids and cessation of hæmorrhage in women had been observed by Crabbe and Caldwell, of New York, led us to hope that we were on the eve of finding some reliable method of treatment as an alternative to hysterectomy.

He believed also in the germicidal action of high frequency currents in septic pruritus pudendi, and would be glad of an opportunity of trying it by means of a glass intra-uterine electrode in a case of septic puerperal endometritis. He hoped that in time the

cases which gynecologists could safely and hopefully hand over for treatment to their colleagues in the X-ray and electrical departments of medicine would become defined, for there was abundant room for any remedies which could take the place of radical operations.

Dr. HERMAN STEDMAN said that he had selected some half-dozen cases of chronic endometritis and cervical catarrh, and had endeavoured to cure the discharge by means of ionisation with zinc and copper, but that after six treatments of 600 milliampères-minutes had only in one instance succeeded in effecting a cure. The dose used was the standard adopted on the Continent and was arrived at by using the strongest current the patient could bear and maintaining it for a sufficient time, which when multiplied in minutes by the number of milliampères resulted in a total of 600, *e.g.*, 30 m.a. for 20 min.=600 m.a.m.

Dr. F. HOWARD HUMPHRIS wished to bear out the remarks of Dr. Curtis Webb, and from personal experience to testify that, as an adjunct to gynecological treatment, electro-therapy was invaluable. He had used it himself for several years, and had found that results could be obtained from its use which he had been unable to get without it. Various ill-defined pelvic pains and backache could be relieved as surely with the Faradaic current as with a hypodermic injection of morphia, only it was not with every Faradaic coil that these results could be obtained; different lengths of wire were needed in different cases, but in most conditions, in which a sedative effect was required, a long, fine wire coil, used with a bi-polar vaginal electrode, would give relief in 15 to 20 minutes. In cases of sub-involution, in prolapse, and in all conditions in which the uterus was lacking in tone, electricity was one of the most valuable remedial measures. In these cases static electricity, the vacuum tubes applied locally, and the wave current over the lumbar region, Dr. Humphris had found to be of special benefit, pain being relieved from the first, and the pathological cause being ultimately improved or replaced by the former physiological healthy condition.

Dr. Humphris heartily concurred in the statement as to the value of the incandescent light bath, but preferred the use of the single high candle-power lamp, especially in cases of painful menstruation, and wished that time had permitted him to quote several successful cases. In cervical endometritis Dr. Humphris had been in the habit of using the uncovered copper electrode in the cervix, with the indifferent negative pole made of clay, thus by cataphoresis disinfecting the cervical canal with nascent oxy-chloride of copper. This, he explained, is the procedure of Dr. Betton Massey, under whom he had worked for a little time, and to whose teaching and book (a) he owed a deep debt.

In conclusion, Dr. Humphris added to the plea in the valuable paper of Dr. Curtis Webb for the more general use of electricity as a therapeutic agent in gynecological practice, not as a universal panacea, but as a most useful addition to the usual means of resource, not necessarily as a substitute for, but as an adjunct to, the more classic forms of treatment, as a palliative in many cases of pain, and as a curative agent in those cases which are amenable to its influence.

The PRESIDENT (Dr. Macnaughton-Jones) said that years since Charles Goodell had taught him that there were things in gynecology we had to "learn to unlearn"—practices we followed that we had to abandon, others we despised which we were forced to accept. The one thing we all had to unlearn was bias and prejudice. A good deal of both had existed with regard to electrical treatment in gynecology. This might be explained by the fact that we had hitherto been generally ignorant of the nature and structure of electricity, and how the different kinds operated in their therapeutical applications. Physicians desiring to be exact looked with suspicion on a treatment which they regarded as empirical, and the action of which they could not explain. Hence a bias and scepticism prevailed, but this should not prevent the acceptance of

new facts and the adoption of more rational methods. The late Dr. Charles Routh, almost simultaneously with Cutter, in the sixties, advocated electrical treatment; then came Tripiet, and, following him, Apostoli. When the latter's methods and results were published, he (the President) had procured all his appliances, and had tried both electro-causés and the Faradaic treatment. For the latter he used different coils and the high-tension battery, with the various-sized coils recommended by Apostoli, and which had just been referred to, with the vaginal and intra-uterine bi-polar electrodes.

With regard to electro-causés he had so serious a result in one case that he abandoned it altogether. The patient was a lady who suffered from cataleptic and hystero-epileptic attacks, associated with profuse hæmorrhages from a fibromatous uterus. Every practical precaution was taken in the application of the current both as to strength and antiseptis. At first she apparently did not suffer from the treatment. A skilled electrician was present at each sitting, which was given in bed; suddenly she developed symptoms of peritonitis, which proved fatal. Apostoli pointed out that this class of patient was particularly susceptible and the most risky to treat. With regard to Faradaisation in amenorrhœa and dysmenorrhœa, he had varying results—both with the constant and Faradaic currents. In many cases, as might be expected, there was no influence on either the flow or the pain.

The present discussion had, however, rather turned on cataphoresis and ionic medication—of this he (the President) had no personal experience in gynecological cases. There was no doubt in his mind from the reports he had read of the results in other hands that this method of treatment might be very beneficial in certain affections of the female genitalia, but he quite agreed with Dr. Routh that there were cases in which the delay necessitated in carrying out the treatment might be disastrous to the patient. He could not agree that curetting only removed the mucous membrane. It affected intimately the underlying muscular structure and set up a new circulatory relation between the uterus and adnexa through the blood vessels and the lymphatics, having a most important effect on the latter. Of course he referred to thorough curetting and at times tamponading of the uterus, not to mere superficial and co-called scraping. The all-important point, in deciding on any form of electrical treatment, was diagnosis. Apostoli had emphatically insisted on this. In many forms of adnexal disease such treatment was not only inapplicable and useless, as, for example, in pyosalpinx, but extremely dangerous, not merely from the point of view of delay, but from the nature of the interference itself.

#### CASE OF PLACENTA PRÆVIA IN WHICH IT WAS DEEMED ADVISABLE TO PERFORM CÆSAREAN SECTION.

Dr. MUNRO KERR, of Glasgow, reported a case of Cæsarean section for placenta prævia. The patient—a lady 28 years of age—was seen with Dr. McEwen, of Helenborough; she was one week from full term, and had been curetted by Dr. Donald, of Manchester, for fibroid tumours of the uterus. She was considerably better for this operation, and soon after became pregnant. For a few weeks before full term hæmorrhage occurred from the uterus on several occasions, and an examination under an anæsthetic revealed the presence of a centrally situated placenta prævia. The fibroid tumours, which are situated centrally over the fundus, had become considerably larger. After careful consideration of the case, Dr. Munro Kerr came to the conclusion that the best treatment would be Cæsarean section, since it held out the best prospect of saving the child's life, and of avoiding the risks to the mother so likely to accompany a case of placenta prævia. Further than this, removal of the uterus was likely to be soon required, and the chance of any further pregnancy was small. The friends having given their consent, he performed Cæsarean section, removing a centrally situated placenta prævia and delivering a living child. The uterus was then removed by supra-vaginal amputation. It contained a number of fibroids, the largest one on the anterior

(a) "Conservative Gynecology and Electrical Therapeutics." By G. Betton Massey, M.D., Philadelphia.

wall about the size of the closed fist. The patient made a good recovery except for a slight attack of pleurisy on first getting up.

Dr. Kerr had seen one other case in which similar treatment would have saved the child, and, in all probability, the mother also. It was a case of central placenta prævia in a primipara of 36 years of age with a generally contracted pelvis. Delivery was finally effected by craniotomy after version. Judiciously chosen he was convinced there was a place for Cæsarean section in certain cases of placenta prævia. By the ordinary methods of treatment placenta prævia had a maternal mortality of 6-8 per cent. and a foetal of 50-60 per cent. in hospital practice, and the respective mortalities were much larger in general practice. In a carefully chosen case at full term, not interfered with, and where there was every prospect of a difficult extraction if the child was delivered *per vias naturales* would Cæsarean section have a higher maternal mortality than 6-8 per cent.? Certainly not.

In fact in a series of cases where these respective treatments were employed Cæsarean section would probably give a lower mortality, for he knew of nothing more likely to be followed by death or grave septic mischief than a difficult extraction with a placenta prævia. With a full term child this operation, too, would certainly give it a much better chance of surviving.

He only claimed that in certain well-selected cases at full term Cæsarean section had a place, and was sound treatment.

Sir WILLIAM SMYLY said that in the case recorded where placenta prævia was complicated by uterine myomata, Cæsarean section followed by hysterectomy was undoubtedly the correct line of treatment, and he most cordially congratulated Dr. Munro Kerr upon its success. Both conditions called for relief, and it was better practice and involved less risk to both mother and child to treat them simultaneously. He had not himself met with a case of placenta prævia in which he thought an abdominal operation advisable.

Dr. GRIFFITH had been convinced for some years that certain special cases of placenta prævia would be best treated, both in the interests of the mother and the child, by Cæsarean section. The difficulties, and therefore the dangers, of placenta prævia, were very slight when dilatation of the cervix was easy and labour pains powerful, but the difficulties increased with the difficulty of dilatation and the absence of pains, and it was in the cases where the placenta was the so-called "central," the cervix closed and tough, and considerable hæmorrhage present that the danger was great.

In January, 1905, he was called by Dr. Crabtree, F.R.C.S., of Weybridge, to a lady, 38 years of age, who had two severe hæmorrhages. The child was lying in the first position above the brim, the cervix closed and tough, the pelvis of normal size, and the vagina narrow. Both husband and wife expressed the wish that the life of the child should be saved, and readily agreed to Cæsarean section, which was at once performed. Both mother and child made an excellent recovery. The need of special care to ensure complete detachment of the placenta had impressed itself upon Dr. Griffith. He had to remove a piece of firmly adherent placenta, which he had left behind, from the lowest part of the uterine cavity, 36 hours after the operation. The child—a boy—is living and strong, and there has been no subsequent pregnancy.

Vaginal Cæsarean section, which, in his opinion, would be the operation of election in a similar severe case of accidental hæmorrhage, would probably involve too severe hæmorrhage in a case where the placenta was prævia.

The PRESIDENT said that the case brought before them raised the all important question of the justification for Cæsarean section in placenta prævia. It had quite recently given rise to one of the most important discussions at the McDowell Centennial Anniversary in America, in which their late president, Dr. Herbert Spencer, took part. The case brought forward by Dr. Munro-Kerr was obviously, from the myomatous complication, one in which the operation was indicated, as also in that mentioned by Dr. Williamson.

Such complications demanded operation. He (the President) agreed that in primipara, with a rigid and undilatable cervix or abnormally small introitus, especially with central attachment, the step was indicated. But he thought that many advocates of Cæsarean section greatly exaggerated the dangers to the mother of this complication. Henry Fry, in the discussion referred to, instanced the reports of 161 cases distributed between six operators, and also quoted Holmes, who had collected 1,029 cases distributed between 11 surgeons, and the mortality in both instances did not exceed 3.3 per cent.

The whole question was one well worthy of a special discussion, when the vast experience gained in the British Lying-in and Maternity Institutions could be availed of, and an authoritative opinion might go forth from this Section. The well-known teachings of the Irish school, from which he himself hailed, and which for years he had followed, convinced him that only in very exceptional instances was Cæsarean section called for. As was stated by Fry, if we allow for the occurrence of placenta prævia once in a thousand pregnancies, then the demand for Cæsarean section would not exceed one in 20,000. There were many incidental points which it would be well to have debated if the subject came up for special discussion in the Section.

#### NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD IN LIVERPOOL, OCTOBER 15TH, 1909.

Dr. J. W. MARTIN (Sheffield) President, in the Chair.

Dr. A. J. WALLACE (Liverpool) showed an extreme example of hydrocephalus, and also a uterus and vagina removed for

##### CARCINOMA OF THE CERVIX.

extending superficially over the entire anterior vaginal wall. The uterus was freely movable, and there was no infiltration of the parametric tissues. The vagina was first separated from below, and its lower end invaginated and closed by a double row of sutures. The operation was completed by the abdomen, an ordinary pelvic dissection being performed. The pelvic glands on the left were enlarged and were freely cleared out. Those on the right side were much enlarged and too intimately adherent to the iliac vessels to justify removal.

Dr. J. E. GEMMELL (Liverpool) showed a good example of a rare foetal monster. *Symelus*.

Miss IVENS (Liverpool) read the notes of five cases of

##### TUBERCULOUS SALPINGO-OVARITIS.

In four the disease was apparently primary in the tubes, in the fifth there was an associated bone lesion. The ages varied from 20 to 36. Dysmenorrhœa was the only symptom common to all. Dysuria occurred in four cases, and menorrhagia in three. In no case was the uterus removed, though both tubes were extirpated in each case. A portion of ovary was left in all but one instance. In all there has been an immediate and maintained good result, with gain in weight and freedom from pain. In one tuberculous peritonitis developed but subsided with tuberculin treatment.

##### GASTRIC OR DUODENAL ULCER AS A CAUSE OF PELVIC PERITONITIS.

Dr. ARNOLD W. W. LEA related 3 cases of pelvic peritonitis which had developed in patients suffering from symptoms of gastric or duodenal ulcer, and called attention to the possibility of perforating ulcer being a causal factor in the production of the disease. Two of the patients were single, one was married, but sterile. In all the usual sources of ascending infection could be excluded. In each instance there was a history of long continued dyspepsia, which was followed by a severe illness with symptoms of general peritonitis, apparently due to rupture or leakage of an ulcer. It is well known that in perforation of a duodenal ulcer the fluid tends to flow into the right iliac fossa, and into the pouch of

Douglas. If no operation is performed and the patient is able to withstand the peritonitis which follows, the fluid will tend to collect in the floor of the pelvis. This may undergo complete absorption, but it is possible that the inflammatory re-action which ensues may result in the formation of adhesions around the uterus and appendages. In these cases the uterus was found at the operation to be firmly adherent to the pelvic floor with a variable degree of perimetritis and fixation of the appendages. Ventro-fixation was carried out with relief to the pelvic symptoms.

Dr. LEITH MURRAY (Liverpool) read a paper on the anti-autolytic action of blood serum and its relation to hyaline degeneration in uterine fibroids. Small pieces of a fibroid incubated in serum very soon develop distinct hyaline change limited to the connective tissue. Muscle fibres take a purely passive part in the process. The hyaline appearance produced resembles hyaline degeneration occurring naturally both to general microscopical examination and in staining peculiarities.

The clear fluid cavities in œdematous fibroids do not result from thinning out of surrounding hyaline material, as Kelly and Cullen assert, but the fluid in them is directly responsible for that change, and can produce it in vibrio.

## CORRESPONDENCE.

### FROM OUR SPECIAL CORRESPONDENTS ABROAD.

#### FRANCE.

Paris, Oct. 24th, 1909.

#### THE SERTHERAPY OF TETANUS.

ANTI-TETANIC serum is, like the serum of Behring-Roux, an anti-toxin serum which renders inoffensive the toxin circulating in the blood by combining itself with it, but possesses no action on the bacilli which produced the toxin.

The bacillus of tetanus discovered by Nicolaier remains fixed in the wound it infects, a wound anfractuous, irregular, and soiled by earth, mud and animal dejections. The toxin it creates diffuses, on the contrary, beyond the wound, following, as Marie proved, the tract of the nerves until it reaches the nerve centres and fixes itself on the nerve cells, for which it possesses a particular affinity, thus producing the characteristic contractions of tetanus.

The method of preparing the serum for tetanus is rather too complicated to recall here. It will suffice to say that it is prepared like similar serums by immunisation of animals. MM. Roux and Vaillard employ the serum of the horse. According to Dr. Torres, an authority on the subject, the serum may be injected subcutaneously into the veins, along the nerve or in the neighbourhood of the nerve centres.

Hypodermic injections, in order to be efficacious, must be employed at the very outset of the accident—that is to say, before tetanic symptoms have set in; they should also be abundant, according to Louis Martin, to have any chance of being successful; two to three ounces should be injected daily for at least a week, as the immunity conferred by each injection does not extend beyond ten days, and if at this moment the bacillus has not disappeared from the wound, tetanic symptoms set in.

Intravenous injections have also been practised as creating a more rapid action than the subcutaneous method.

Here also large doses are indicated. Louis Martin and Darré successfully injected as much as three ounces into the vein of a boy eight years of age. However, similar doses should be injected under the skin concurrently with the above.

Apert and Lhermitte recommend para-radicular injections into the canal of the sacrum. This method appears to possess advantages; it is easy to execute, can be renewed as frequently as necessary; it reaches the nerve at the point where it divides into its numerous branches (cauda equina). Each branch is thus plunged in an anti-toxin solution at the point

where it is not yet enveloped in the membranes of the cord.

As to the results of the treatment of tetanus by the serum method, Roux and Vaillard declare that the action is purely but yet really preventive, but it has no effect on the infection.

The immunity conferred is only temporary, and disappears completely between the fortieth and fiftieth day. The quantity of serum necessary to prevent fatal consequences increases in proportion to the number of days that have elapsed after the primary infection. Where a certain time has elapsed—say a month or six weeks—the serum is useless.

Has the serum a curative effect? The question was much debated two years ago at the Académie de Médecine. While some were entirely opposed to the idea of any curative action, others affirmed having obtained cures in the active period of the disease, but all were agreed on its prophylactic efficiency.

Consequently, each time that a wound is found to be soiled with earth, mud, or manure which may contain tetanic spores, the surgeon's duty is to inject the anti-toxin serum daily until the wound be completely healed. However, local antiseptic treatment should not be neglected; complete disinfection of the wound and application, if possible, of dry serum reduced to powder, not forgetting the general classic treatment; isolation in a darkened room, administration of chloral and bromides in large doses, and subcutaneous injections of phenic acid as recommended by Bacelli.

If, in spite of all, tetanus sets in, large doses of serum may be injected, and perhaps also intrarachidian injections of sulphate of magnesia, as strongly advocated by Blake, Griffon and others.

#### GRANULAR CONJUNCTIVITIS.

Soft, granular lids are a common affection, and divers forms of treatment have been advocated and used. It must be said that each and every one of them have shown certain advantages. Touching the granulation with a solution of nitrate of silver was common practice, but it was superseded by the method of Dr. Hache, which is very successful, and consists in painting the surfaces after dry rubbing with a piece of antiseptic cotton wool, so as to provoke bleeding, with a solution of iodine in vaseline oil (iodine, 1 gr.: vaseline oil, 2 dr.).

Another agent would seem to be particularly successful in the treatment of granular lids: it is hermophenyl, an organo-metallic powder containing 40 per cent. of mercury, and very soluble in water; it has the advantage of not irritating the tissues, while its toxic effects are insignificant. The salt is employed in solution of 1-30 for purulent ophthalmia. For granular conjunctivitis the strength of the solution is 15 per cent., or 30 gr. for 2½ drachms of distilled water, and painted over the surface of the conjunctiva. For bathing the eye, a solution of 1-200 is employed: the results are much superior to those obtained with boric acid, the antiseptic properties of which are illusory. By this treatment a cure is obtained in about 20 days, or half the time required by the iodine treatment.

Ciliary blepharitis is also very amenable to treatment with hermophenyl. A plug of cotton, moistened with a solution of 1-20, and rubbed briskly on the edges of the lids every two days, produces a rapid cure.

#### GERMANY.

Berlin, Oct. 24th, 1909.

#### THE NEW ERA OF OBSTETRICS AND VAGINAL CÆSAREAN SECTION IN CONTRACTED PELVIS.

THIS is the title of a contribution by Prof. Dürhsen to Hegar's Beiträge 14, I. Cæsarean section and pubiotomy, says the writer, are to be avoided as much as possible. In placenta prævia he recommends the metreurynteur in the first instance for the arrest of hæmorrhage. It also affords the smallest infant mortality. With moderate hæmorrhage during the pregnancy, and a closed os uteri, an attempt should be made to carry on until the normal end of the pregnancy, by means of anti

and aseptic tamponade of the vagina. With more free hæmorrhage during the pregnancy, and a closed os, metreuryis with preliminary moderate dilatation by means of the finger along with rupture of the membranes is indicated, with possible vaginal Cæsarean section. During the labour internal version should be effected, and with moderate pulse extraction may follow, but only when the os uteri is fully dilated. In all other cases combined version is to be preferred on account of the ease with which it can be carried out, and also on account of lesser infant mortality. If the hæmorrhage is arrested it will only be necessary to watch the further course of the labour and see that the strength of the patient is maintained. For many myomata and also for many ovarian tumours encountered during labour vaginal removal is the proper way, when the uterus can be emptied at the same time. In case of normal pelvis there is no reason to give up vaginal Cæsarean section in favour of the supra-symphysary form of operation. It is within his view to displace suprapubic Cæsarean section in contracted pelvis by vaginal Cæsarean section combined with Ritgen's gastro-elytrotomy, as from the vagina he opens the cervix uteri extraperitoneally, draws the neck on one side, then opens the abdominal wall subperitoneally, and through the passage thus made extracts the child above the pelvis. For all doubtful cases it is necessary that the drainage should be good and that there should be no tension anywhere. The most perfect drainage is attained when the anterior vaginal arch is opened and kept open through the vaginal Cæsarean section, and the most perfect relaxation when the bladder is separated from the uterus, and the whole of the uterine wound left open.

#### ADRENALIN IN CÆSAREAN SECTION.

This question is discussed by Dr. M. Bogdanovics in the *Zentralbl. f. Gyn.*, 12, 09.

The maximum dose of adrenalin is, he says,  $\frac{1}{2}$  mg., equal to 15 drops of a 1-1,000 solution. Even in cases of general infection it is just as useful as for the arrest of hæmorrhage, in combating collapse and cardiac failure. In a case referred to, one of generally contracted flat rickety pelvis, the conjugate was 7.3. In spite of powerful contractions the head did not enter, and the bladder gave way. Cæsarean section was performed. The uterus contracted badly, and there was free atonic post-partum hæmorrhage. An injection was made into the uterine wall of 1ccm. of a 1-1,000 solution of adrenalin, when the uterus contracted with effect.

#### VENENANÆSTHESIE.

This method of producing anæsthesia has been practised in the human subject by Prof. A. Bier, and a report of his experiences in 134 cases is given by him in the *Berl. Kl. Wochensh.*, 11/09. In 115 of the cases the result was good, in 14 gratifying, and in 5 it was unsatisfactory. By intravenous injection the anæsthetising solution passes quickly from the veins into the tissues, and the method far surpasses local anæsthesia. He makes use of a graduated syringe containing 100 ccm. The needles have very thin walls, and are connected with the syringe by very thick indiarubber tubing into which a stop-cock is inserted. Near the point of the needle is a circular groove, into which the thread used in tying the vein runs. The anæsthetising fluid is a 0.5 per cent. solution of novocain in physiological saline solution, and used at about the normal body heat. It was found of advantage to make the part to be operated on as bloodless as possible. This is done in the usual way with the Esmarch expulsion bandage, but the bandage must be put on very firmly. Where there is infection, however, or tumours with infected cells, the bandage need not be applied, but it may in all cases of necrosis and tuberculous joints. At the upper end of the expulsion bandage that is above the spot that is to be operated on, the proper bloodless bandage of thin indiarubber is to be applied in many folds. A second bandage of the same material is now to be applied below the field of operation, and the injection is to be made between the two bandages. It is suggested

that for exposing and opening of the vein Schleich's "Infiltrationsanæsthesie" should be made use of. The vein must be large enough to take the cannula easily; for the leg the saphena is named, for the arm the cephalic and basilic or the median vein of the elbow. If the vein is not visible it must be sought for by transverse incision. The injection must always be made in a peripheral direction. Intravenous injections are not more poisonous than those into the tissues. "Venous anæsthesia in completeness and amplitude is destined to put all other methods of local anæsthesia into the shade."

#### AUSTRIA.

Vienna, Oct. 24th, 1909.

#### STATUS THYMICO-LYMPHATICUS.

NEUSER, in a long paper at the Budapest International Congress, endeavoured to form a differential diagnosis of this disease, which he said was as yet very badly defined. Paltauf had described a number of cases under the title of the lymphatic chlorotic constitution as a result of his anatomical research. Some of his pupils, particularly Bartels, Kyrles, etc., have found a hypertrophic and atrophic stage in the scrotum, ovaries, and arteries. Neuser thinks the individual terms, status thymicus-lymphaticus and hypoplasticus is not sufficient to cover all the clinical varieties. At this point he gave a few clinical histories and anomalies to illustrate the point. Two individuals, he said, had reached their sixtieth year, both of whom had been afflicted with infectious diseases as well as typhoid and dysentery, and now were healthy and strong, but on the other hand two younger people suffering from this anomaly take trifling diseases such as catarrh, jaundice, or purpura hæmorrhagica, and suddenly die. Pernicious anæmia, lymphatic leukæmia, morbus Basedowii, and Addison's disease, all belong to the same class.

The diagnosis of status-lymphaticus depended largely on a careful examination and true value of the symptoms, such as enlargements, increased growth, delicate structures, dilatation of the pelvis in the male, and movement at the epiphysis. In the female late appearance of menstruation, hyperplastic uterus, comparatively small pelvis, hydrocephalus, rudimentary symptoms of morbus Basedowii, osteomalacia, Stokes-Adams' symptoms, and other forms of fibrous polyserositis and cirrhosis of the liver are pathognomonic of the disease. In conclusion, he affirmed that the diagnosis was not so easily accomplished clinically as in the post-mortem room, yet the clinician, with careful observation, could often recognise rudimentary conditions in a hypoplastic constitution that were characteristic.

#### OBESITY.

Van Noorden contributed to the Congress an interesting paper on the ætiology of fat, which he divided into two forms: (a) the active overfeeding; (b) the necrotic form of fat; but frequently both were combined. The first arising from over nutrition and reduced energy, is quite reasonable and easily demonstrated, but the second is more difficult to explain, where the intake is less than the normal, though the average work is more than the energy supplied, which may be termed constitutional obesity. After decenniums of discussion we are still without a reasonable cause beyond the hypothesis that the oxidising energy of the organism is reduced. This is a factor all are agreed on, but the connection with the glands, and particularly the thyroid, is an active agent in this oxidising transition. Primary thyrogenic fat is conceivable when any changes take place in the thyroid gland such as atrophy, degeneration, functional disturbance, etc., but this thyrogenic condition has also a secondary form, where the functional anomaly of the gland awakens a disorder in other organs, such as the pancreas, hypophysis cerebri, thymus and suprarenal gland, which are co-related by means of internal secretion. The importance of this inquiry is not only theoretical, but demands our attention in practice as to how therapy should be conducted.

## FROM OUR SPECIAL CORRESPONDENTS AT HOME.

### EDINBURGH.

**APPOINTMENT OF PRINCIPAL TO THE ABERDEEN UNIVERSITY.**—The King has been pleased, on the recommendation of the Secretary for Scotland, to approve the appointment of the Rev. George Adam Smith, M.A., D.D., LL.D., to be Principal of the University of Aberdeen, in succession to the late Principal Marshall Lang, whose death was referred to in this column a few months ago. Dr. George Adam Smith is one of the most eminent clergymen in the United Free Church, and is esteemed alike as a preacher, a scholar, and a personality. He is 53 years of age, and after passing through the usual theological training at the New College, Edinburgh, he supplemented the curriculum there by studying the Semitic languages at Tübingen and Leipsig. In 1880 he was appointed to conduct the Hebrew classes in the Free Church College, Aberdeen, on the suspension of Robertson Smith, probably the greatest scholar the Free Church has ever produced. After an interval of 12 years he was appointed to the chair of Old Testament Language, Literature, and Theology in Glasgow, and during his tenure of that office his reputation has steadily risen. There may be, perhaps, a certain feeling of disappointment that a member of our own profession has not been elevated to the Principalship of Aberdeen; but Dr. George Adam Smith is a man who enjoys an almost European reputation. He is a brilliant scholar, a man of the most liberal views, and one who takes an active interest in social work. He is endowed with a most persuasive and charming personality, and seems in every way an ideal man for the position to which he has just been raised.

**ISOLATION HOSPITAL AT DINGWALL.**—The newly-constructed Isolation Hospital in connection with the Ross Memorial Hospital at Dingwall was opened on October 21st by Lady Munro of Foulis. The hospital, which has cost £1,400 to build, is situated in the rear of the present building, and will secure complete separation of different infectious diseases sent from various parts of the county. Dr. Bruce, introducing Lady Munro, said that during the past six years 3,000 patients had been treated, including 140 cases requiring major operations, and 625 cases of fever.

**ROXBURGH, BERWICK, AND SELKIRK ASYLUM.**—The Medical Superintendent's report shows that there were 316 resident patients on May 15th last; 40 men and 32 women were admitted; 405 patients were under care during the year, of whom 43 were discharged, and 38 died. Hereditary predisposition was ascertained to exist in 32 (44.4 per cent.) of the new cases; in 24 cases (33.3 per cent.) there were suicidal tendencies. In 76.4 per cent. of the patients the physical condition was poor, and in 5.6 per cent. very bad. Of the 43 patients discharged, 21 had recovered, 10 were relieved, and 2 not relieved. The recovery rate was 43 per cent., that for the previous 36 years since the asylum was opened being 33.4 per cent. The process of reconstruction of the asylum, which has now been in progress for 13 years, is now within measurable distance of completion.

### GLASGOW.

**THE TEACHING OF ANATOMY IN GLASGOW.**—Professor Bryce, as the newly appointed Professor, in his opening address on the 18th inst., took "The Teaching of Anatomy in Glasgow" as his subject. After alluding to the earlier occupants of the chair, he pointed out that the Glasgow chair, which was founded in 1718, was from the first a chair of comparative anatomy, including in early days zoology, vertebrate and invertebrate, physiology, pathology and even surgery. In 1807 zoology was separated, and physiology in 1839; but, notwithstanding this specialisation, the chair had always remained one of comparative anatomy, and the ideal of 1720, viz., that the university teaching of anatomy involved the profession of everything that elucidated the structure of the human body, remained the ideal of 1909. Joseph Black, the famous chemist,

was an occupant of the chair. Allen Thomson, appointed in 1848, was the first who devoted himself wholly to anatomy. He was a pioneer in the study of embryology, was associated with Sharpey, Cleland, Schäfer and Thane in the seventh, eighth and ninth editions of "Quain's Anatomy," and added much to the reputation of the chair. Professor Cleland, who followed, had been generally acknowledged as the most philosophic anatomist of his time. He was specially interested in morphological questions, more particularly in the morphology of the skull. In his "Animal Physiology" and his various addresses, such as that on Evolution, Expression and Sensation, and the Classification of the Vertebrata, he developed with argumentative force and subtlety his conception of definite and determinate evolution as opposed to that of natural selection. Professor Bryce then shortly indicated the lines on which he hoped to see the study of anatomy developed. He claimed that the teaching of histology—that was of normal as opposed to applied or physiological histology—would more properly be taught in the anatomical department. He next referred to the paramount importance, for the comprehension of anatomical fact, of a study of development, and pointed out that the enormous advances in recent years of the knowledge of the details of human development placed the teacher in an increasingly advantageous position for the demonstration of embryological facts.

**THE ANNUAL DINNER OF THE SOUTHERN MEDICAL SOCIETY.**—Dr. Peden, the President, took the chair at this annual function, on the 21st inst. Dr. Chas. Robertson, in proposing the health of the guests, desired information from Dr. Roberts (the newly appointed Medical Officer of the School Board) as to what was going to be the attitude of himself and his assistants in regard to the treatment of school children and their relationship to the general practitioner in the city. Dr. Roberts stated that he would endeavour to protect the interests of the general practitioner, and that only those in necessitous circumstances would be treated either by himself or his assistants, and he anticipated that their interests would in no way clash with the interest of the general practitioner.

**REQUEST TO THE GLASGOW WESTERN INFIRMARY.**—By the will of the late Mr. Alexander Fleming, of Messrs. W. Baird and Co., coal owners, the Glasgow Western Infirmary will benefit by the sum of £10,000. Altogether, over £61,000 has been bequeathed by the deceased gentleman to Glasgow and West of Scotland institutions.

### BELFAST.

**INSPECTION OF MILK SUPPLY.**—A special meeting of the Public Health Committee of the Corporation was held last week to consider the report of the Medical Superintendent Officer of Health on the Sanitary (Veterinary Inspectors') Order, 1908, and also a letter from the Local Government Board on the subject of Section 19 of the Tuberculosis Act, in respect of dairies outside the area of the city. In his report Dr. Baillie pointed out that the order substitutes the Veterinarian for the Medical Superintendent Officer of Health for practically all matters relating to the milk supply of the city. Since the Medical Officer is responsible for matters concerning the health of the city, the objection to the Order is obvious. Divided responsibility would be most objectionable in such matters. The Order may be very useful in country districts where the provisions of the Dairies, Cow-keepers, and Milkshops Order have not been carried out; but it would be most unsuitable and unsatisfactory for Belfast or any other large city. The general opinion of the Committee was that it would be unworkable and impracticable in Belfast, and a small deputation was appointed to wait on the Local Government Board on the subject.

**QUEEN'S UNIVERSITY OF BELFAST.**—The first Matriculation Examinations under the new University were held in Belfast during the past week, and the number of entries is likely greatly to exceed the entries at the College in any previous year. Since some of the entries will be made through the Royal University, and some

OCT. 27, 1909.

through the Intermediate Education Examinations, it is impossible to estimate the numbers as yet. The third and fourth year medical classes have been much upset by the new regulations, some being crowded and others nearly deserted, and no doubt it will take a few sessions to straighten matters out, and get properly into the running of the new curriculum.

## LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

### RELIGION AND MEDICINE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your able leader of Wednesday last I venture to think you put your pen on the beginning and end of Christian Science, when, while exposing its "side of positive nonsense," you display religion's opportunity "to pluck from the memory a rooted sorrow, or to cleanse the bosom of that perilous stuff that weighs upon the heart."

The Christian Scientist appears to be making the error common to all flesh—riding his idea to death—he sees his speciality in every case. On the other hand what Christian Science might be able to do can be done, has been done and is being done by the orthodox in all the ordinary religions. Except therefore, perhaps, as a new money-making machine the *raison d'être* of Christian Science is not easy to see. As to the wider study "Religion and Medicine," which is the heading of the leader I am referring to, that is a matter lost in the illimitable sea of change, as shown for example in the history of Lombroso's mental life or in the following lines which "Vanoc" a few weeks ago had in one of his articles:—

"A fire-mist and a planet,  
A crystal and a cell,  
A jelly fish and a saurian,  
And caves where cavemen dwell:  
Then a sense of law and beauty.  
A face turned from the clod,  
Some call it evolution,  
And others call it God."

I am, Sir, your truly,  
G.F.D.

### THE SCOTCH COLLEGES AND THE MEMBERSHIP DIPLOMA.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Some time since an open letter appeared in your columns addressed to the Royal College of Surgeons of Edinburgh by the Association of Medical Diplomates of Scotland with reference to the creation of a membership diploma. As a Scotch licentiate of many years' standing, it would interest me greatly to hear if the proposal was favourably or otherwise received by the Council of the College. In my own practice I have found the lack of a membership qualification, that is to say, of one equal in titular degree to that of the majority of my competitors, a serious practical drawback on more than one occasion. So, too, have many of my friends who hold the Edinburgh conjoint diploma. What logical reason can the College have for refusing the membership that would add so greatly to its attractions: and, more than that, would bring a large amount of money into its coffers? It seems to me, as a plain man, that the day of the provincial university is at hand, and that the Colleges, English, Scotch, and Irish, will soon have to face a sharp struggle for survival. In England the higher diplomates of the two Colleges have secured a virtual monopoly of the larger hospital posts, but that will hardly enable them to compete in the long run with the higher University degrees in surgery. But we are concerned more precisely at present with the Scotch colleges. Why should they not, both at Edinburgh and at Glasgow, unite and take advantage of the permission given them in the Medical Act of 1858 to grant the diploma of M.R.C.S.? Why not, indeed, unless they wish to set up a lasting monument of conceit, that preferred their own selfish and

petty parochial interests to those of the vast body of licentiates whose money they were not above accepting. *Quem deus perdere vult, prius dementat.* I, for one, Sir, trust the Association of Medical Diplomates of Scotland will not let this matter drop.

I am, Sir, yours truly,

L.R.C.S. and P.EDIN.

Staffs, October 26th, 1909.

## OBITUARY.

### DR. T. SPENCE MEIGHAN, OF GLASGOW.

On account of the sudden death of this gentleman, we were able only to chronicle the fact in our last impression, that he was seized with sudden illness in the street, was taken to a nursing home, where he died shortly afterwards without regaining consciousness. Dr. Meighan was a general practitioner in the East End of Glasgow during most of his professional career, but from an early date took a special interest in diseases of the eye, and while engaged in general practice among the poorer population he managed by his ability and by the force of his character to find or make time to cultivate diseases of the eye, in which speciality he attained deservedly a very high reputation not only in Glasgow but in the West of Scotland. For many years he conducted a class on ophthalmology in Anderson's College, Glasgow. He was an excellent teacher, and knew the wants of the general practitioner, and his instruction was always of a practical character. He was ambidextrous, and could operate with equal facility with both hands. It was generally allowed that he was the most expert operator in Glasgow in cases of cataract. He was honoured some time ago by being made a Fellow of the Faculty of Physicians and Surgeons, Glasgow. He wrote several pamphlets on the eye, bearing the mark of acute observation, and of a practical character. His life affords a splendid example of a general practitioner forcing his way to the top of his profession in a speciality under unusual disadvantages and hardships. His sudden death in the fulness of his powers recalls the lines of Dr. Johnson on Dr. Levett:—

"Death broke at once the vital chain  
And freed his soul the nearest way."

### CESARE LOMBROSO.

THE late Professor Lombroso was born at Verona on November 18th, 1835. He was descended from a Jewish family which had attained high positions as doctors, lawyers, rabbis and authors. As a boy Lombroso was well-nigh precocious. At twelve years of age his "Greatness and Decline of Rome" was published, and from that time he steadily began to build that fabric which is now such a remarkable reputation.

## MILITARY & NAVAL MEDICAL NOTES.

**TUBERCULOSIS IN THE NAVY.**—Statistics furnished by the First Lord of the Admiralty, in reply to recent questions in Parliament, show that 2,673 officers and men suffering from tuberculosis were invalided out of the Navy between 1889 and 1906. Of course, the number is comparatively small with so large a body of men, the conditions of naval life, as has been aptly shown, do not tend to induce this disease, so that greater care is suggested in the medical examination of naval recruits. As such strong comments have been made about the discharge from hospital of these military and naval cases to their homes on being invalided, doubtless in more or less advanced stages of the disease, repeated questions have been put in the House of Commons to the First Lord of the Admiralty and also to the Secretary of State for War. A suggestion has been made in one military journal that a small hospital or home for men invalided for

this disease out of the two Services might be established, and it points out that the cost would not greatly exceed the payment of the present invaliding pensions of 9d. or 1s. a day, and turning them adrift.

**KING EDWARD VII. HOSPITAL.**—A letter by a Gunner Major appears in *The Pioneer Mail* of India, appealing to officers to contribute 5s. yearly to this hospital, generally known as Sister Agnes' Hospital. Long since a claim for support of this institution was publicly made. The benefits conferred by it on officers have been very great. Numberless sick and wounded officers were tended with great care and efficiency during the South African War, and the good work has ever since been continued through Sister Agnes' (Miss Agnes Keyser) generosity. It will certainly be a reproach to the military if the pleading for funds by small subscriptions fails to meet with response.

**A TEST OF WAR RATIONS.**—A test of these has been undertaken by a detachment of twenty soldiers, who started from Tidworth on the 11th inst. to march backwards and forwards across Salisbury Plain at the rate of fourteen miles a day. The test is to be carried out as nearly as possible under war conditions, the men sleeping under canvas, and on the march carrying their knapsack, food, and kindling wood, etc., etc. The men will be watched by Army medical officers. The daily ration is to consist of: 1½lb. fresh meat or 1lb. preserved, 1½lb. of bread or 1lb. biscuits or flour, ½oz. tea, ¼lb. jam, 2oz. sugar, ½oz. salt, 1.36oz. pepper, ½lb. fresh vegetables or 2oz. dried vegetables, 2oz. cake tobacco, to last a week.

**DOGS IN WARFARE.**—It has been known for years past that dogs for ambulance and seeking wounded in war have been trained in several European armies. Our own War Office seems the only one among the Great Powers that is hidebound and will give no attention to its importance. It is indeed a melancholy reflection. In the *Army and Navy Gazette*, of the 18th June, 1904, Colonel Frank Howard (retired), Army Medical Staff, wrote an article on "The Use of Dogs in War," tracing the subject back to the times of the Greeks and Romans, and even the saving of Corinth by war dogs. More recently Major Hautonville Richardson, of Carnoustie, N.B., has pressed home the subject, and has been in Melilla experimenting during the present campaign by Spain in Morocco, and confirms the views of Colonel Howard and other medico-military authorities.

## REVIEWS OF BOOKS.

### THE MORPHIA HABIT AND ITS RENUNCIATION. (a)

THE name of Oscar Jennings of Paris has long been associated with the treatment of the morphia habit on which he is the recognised authority. That the vice of morphinism both in this country and on the Continent is steadily on the increase is the experience of most medical men who practise in large cities. It is but one phase of the craving for drugs of the narcotic type which is the besetting sin of civilised people and especially of society women. Almost daily we see in the papers reports of inquests on the victims of this pernicious custom, and yet in all probability not one-tenth of these cases are afforded the light of publicity; the chief anxiety of the friends and relations being to hush up matters and avoid a scandal.

Dr. Jennings states as a fact that one medical man out of four is a drug *habitué*, usually a morphinist. He is probably speaking of a specially selected class and we do not suppose that the statement applies to the great mass of country practitioners actively engaged in the work of their profession. They, as a rule, although leading an arduous life, are a healthy race, but little addicted to vicious habits. The temptation occurs chiefly in the case of young consultants holding hospital appointments, who have to keep up a good

appearance on totally inadequate means. By most authorities it is held that the habit once established is never eradicated. Many victims anxiously seek to cure themselves by taking those widely advertised remedies which almost invariably consist of some preparation of opium or one of its alkaloids. Any temporary benefit that may accrue is fallacious, for the patient is only obtaining his drug from another source. He still takes his morphia but purchases it at another shop.

The question is not so simple as it first appears for the victim of the craze usually resorts to more than one toxic agent. He is often more or less alcoholic, takes morphia or cocaine during the day and veronal at night. It matters little by what channel the drug is introduced into the system, whether taken by the mouth or injected hypodermically, for the effects are equally pernicious. Dr. Jennings devotes an interesting chapter to "Morphinism complicated by Cocainism," and in another describes a case of Heroin habit. The whole work is illustrated by references to cases which have been under his care, many of them being recorded with an abundant wealth of detail. His most interesting observations, however, are those devoted to treatment, and his remarks on the re-education of self-control and the interaction of mind and body are masterpieces of reasoning. This is not the place to divulge his methods which have been laboriously evolved as the result of many years of practical experience, but we cordially commend the book to the careful attention of our readers, feeling sure that they will derive much useful information from its study. Dr. Jennings has done good work and the conclusions at which he has arrived will have a far-reaching influence on the treatment of the disease of which he treats. His cases are graphically described and his description of "a personal relation of a suppression after twenty-five years addiction" is a most impressive narrative.

## MEDICAL NEWS IN BRIEF.

### Honyman Gillispie Post-Graduate Lectures.

THIS course will be commenced to-morrow (Thursday), at 5 p.m., when the Lord Mayor of London, Sir George Wyatt Truscott, Bart., will be present at the Public Introductory Lecture to be delivered by Dr. George Burford on "The Medicine of the Future: Coming Events that Cast their Shadows Before," at the London Homœopathic Hospital, Great Ormond Street.

### Annual Dinner of the Queen's Hospital, Birmingham.

AT the tenth annual dinner of the Past and Present Residents' Association of the Queen's Hospital, at Birmingham, held at the Midland Hotel, Birmingham, on October 22nd, Dr. Blakeney, of Cheltenham, in the chair, Sir James Sawyer, the senior past president of the Association, exhibited some interesting mementos of the early days of the hospital, including a portrait of the founder of the hospital, Mr. Sands-Cox, F.R.S., dated 1862, and a record of the first ten years of the hospital's work, as a charity and as a clinical institution, from 1841.

### National University—Scheme of Scholarships and Prizes.

A SCHEME of scholarships and other prizes for the session 1909-10 in connection with the National University has been issued. As regards the Faculty of Medicine they are as follows:—

In the subjects of the First Professional Examination, or first year's studies:—

Two Scholarships of £25 each, tenable for one year.

Two Exhibitions of £25.

Two Exhibitions of £15.

Other prizes to amount of £20.

In the subjects of the Second Professional Examination, or second year's studies:—

Two Scholarships of £25 each, tenable for one year.

Two Exhibitions of £25 each.

Two Exhibitions of £15 each.

(a) "The Morphia Habit and Its Voluntary Renunciation." By Oscar Jennings, M.D. Pp. 500. London: Baillière, Tindall and Cox. 1909. Price 7s. 6d.

Other prizes to amount of £20.  
In the subjects of the Third Professional Examination, or third and fourth years' studies:—  
Two Scholarships of £25 each, tenable for one year.  
Two Exhibitions of £25 each.  
Two Exhibitions of £15 each.  
Other prizes amounting to £20.  
In the subjects of the Fourth Professional Examination, or fourth and fifth years' studies:—  
Two Scholarships of £25 each, tenable for one year.  
Two Exhibitions of £25 each.  
Two Exhibitions of £15 each.  
Other prizes amounting to £20.

The Scholarships will be awarded soon after the opening of the session, the Exhibitions at the close of the session.

As the scale of fees for the various classes cannot be completed before regulations have been made in regard to the University courses in the Session 1909-1910, the following arrangements have been provisionally adopted in the Faculty of Medicine by the Governing Body:—

The amount payable for attendance on the courses of instruction given in the College for the primary medical degrees of the National University of Ireland will be £14 per annum if the courses are equally distributed over a period of five years. In the ordinary distribution of the subjects for professional examination in certain years the subjects required are greater in number than in other years, so that the fees in those years would vary accordingly.

#### Royal College of Physicians in Ireland.

At the annual meeting last week, the following officers were elected for the year ensuing:—

President: Dr. Andrew J. Horne. Vice-President: Dr. E. MacDowel Cosgrave. Censors: Dr. E. MacDowel Cosgrave, Dr. E. Hastings Tweedy, Dr. Coleman, C.M.G., and Sir W. J. Thompson. Examiners for the Midwifery Licence: Dr. Spencer Sheill and Dr. D. J. O'Connor. Additional Examiners to take the place of an absent Censor or Examiner: Medical Jurisprudence and Hygiene: Dr. H. T. Bewley. Medicine: Dr. O'Carroll. Midwifery: Dr. T. Henry Wilson. Examiners for the Membership: Clinical, Dr. Bewley and Dr. Coleman, C.M.G.; Practice of Medicine, Dr. E. E. Lennon and Sir W. J. Thompson; Pathology, Dr. H. C. Earl and Dr. A. C. O'Sullivan. Supplemental Examiners under the Conjoint Examination Scheme: Biology, Dr. T. P. C. Kirkpatrick; Chemistry, Professor E. Lapper and Dr. Ninian Falkiner; Physics, Dr. W. A. Winter and Dr. E. J. Watson; Pharmacy, Materia Medica and Therapeutics, Dr. Travers Smith and Dr. M. Dempsey; Physiology, Dr. H. C. Earl; Pathology, Dr. F. C. Purser; Medicine, Dr. G. J. Peacocke and Dr. J. A. Matson; Hygiene and Forensic Medicine, Dr. A. Nixon Montgomery. Examiners for the Conjoint Diploma in Public Health: Chemistry, Professor F. Lapper; Hygiene, Dr. W. R. Dawson; Meteorology, Dr. W. G. Harvey. Extern Examiners for the Conjoint Preliminary Examination: Languages, Mr. E. H. Alton, F.T.C.D.; Science, Mr. R. A. P. Rogers; Irish, Dr. C. Maguire. Representative of the College on the General Medical Council: Sir John Moore. Representatives of the College on the Committee of Management: Dr. Walter G. Smith, Sir John Moore, and Dr. Craig; Treasurer: Dr. H. T. Bewley. Registrar: Dr. James Craig. Librarian: Mr. R. G. J. Phelps. Architect: Mr. A. E. Murray. Law Agents: Messrs. S. Gordon and Son; Land Agents: Messrs. Townshend. Dr. Walter G. Smith, F.R.C.P.I., was elected King's Professor of Materia Medica and Pharmacy in the School of Physic, Ireland, and Dr. Henry Jellett, F.R.C.P.I., was elected King's Professor of Midwifery in the same School.

#### University College, Dublin.

THE following appointments to vacancies in University College, Dublin, have been made by the Dublin Commissioners:—

Dr. Hugh Ryan, M.A., D.Sc., Professorship of Chemistry; Dr. J. A. McClelland, D.Sc., Professorship of Experimental Physics; Dr. George Sigerson, M.D., Professorship of Zoology; Dr. E. P. M'Loughlin, M.B., Professorship of Anatomy; Mr. J. S. M'Ardle, M.Ch., F.R.C.S., Professorship of Surgery; Dr. B. J. Collingwood, M.D., Professorship of Physiology and Histology; Dr. E. J. M'Weeney, M.D., Professorship of Pathology and Bacteriology; Dr. J. M. Meenan, M.D., Professorship of Hygiene and Medical Jurisprudence; Dr. Martin Dempsey, M.D., Professorship of Materia Medica and Therapeutics; Sir Christopher Nixon, Bart., M.D., Professorship of Medicine; Dr. Alfred Smith, M.B., F.R.C.S., Professorship of Midwifery Gynaecology; Mr. J. J. Dowling, M.A., Lectureship in Physics; Mr. J. Bayley Butler, M.A., Lectureship in Botany; Dr. L. Werner, Lectureship in Ophthalmology; Mr. J. L. Potter, L.D.S., Lectureship in Dental Mechanics; Mr. E. Sheridan, F.R.C.S., L.D.S., Lectureship in Dental Surgery.

#### University College, Cork.

THE following appointments have been made by the Dublin Commissioners to vacant offices in University College, Cork:—

Professor of Anatomy: Dr. D. P. Fitzgerald. Professor of Archaeology: Dr. B. C. A. Windle. President. Professor of Botany: Major H. A. Cummins, M.D. Lectureship on Mental Diseases: Dr. J. J. Fitzgerald.

#### Royal Colleges of Physicians and Surgeons of Edinburgh, and Faculty of Physicians and Surgeons of Glasgow.

THE following candidates having passed the requisite examinations of the above Board in October, were admitted Diplomates in Public Health:—

Alfred B. Darling, Richard L. Bolton, Cecil C. Murison, Jamesina J. Marr, Francis W. Greaves, James B. Miller, Douglas P. Blair, Richard B. Davidson, and John Allan.

At the same sederunt the following candidates passed the First Examination in Public Health:—

Louis W. C. Macpherson, Laurence Gibson, William H. Mackenzie, Agnes E. Porter, John Reid, Byramji S. Tarapurwalla, and John Scott.

#### Royal College of Surgeons of Edinburgh—Fellowships.

AT a meeting of the College, held on the 19th inst., the following gentlemen were elected Fellows:—Alexander Allan, L.R.C.S.E.; Robert B. Anderson, M.D., L.R.C.S.E.; Walter E. Barrett, L.R.C.S.E.; Oliver Carlyle, L.R.C.S.E.; Alexander E. Chisholm, M.B., Ch.B.; Ramsay L. Daly, M.D.; Ezra N. Drier, M.D.; Charles G. Edmonston, M.B., Ch.B.; Mark S. Fraser, M.B., Ch.B., D.P.H.; John D. Harmer, M.B., Ch.B.; Robert H. Jamieson, M.B., Ch.B.; James Kirkwood, M.B., Ch.B., I.M.S.; John McCulloch, M.D.; Alexander C. B. McMurtrie, M.B., Ch.B., D.P.H.; Herbert M. Moran, M.B., C.M.; John Murdoch, M.B., Ch.B.; Frank P. Patterson, M.D.; Francis E. Price, M.R.C.S.Eng.; Vivian H. Roberts, L.R.C.S.E., I.M.S.; William Tarr, M.B., Ch.B., I.M.S.; Robert Telford, M.D.; James A. Thwaites, M.B., C.M.; and Frederick H. Wallace, M.R.C.S.Eng.

#### Society of Apothecaries of London.

THE following candidates, having passed the necessary examinations, have received the L.S.A. Diploma of the Society, entitling them to practise Medicine, Surgery, and Midwifery:—N. B. Benjafield, H. S. Brown, B. Robertshaw, S. H. Scott, and G. Tate.

#### University College Hospital—School Prizes.

THE following medical scholarships tenable at University College and at University College Hospital have been awarded: The Bucknill Scholarship, value 135 gs., to Mr. C. I. de Silva, of Colombo; entrance scholarship, value 55 gs., to Mr. R. J. Clausen, an old pupil of University College School; the Epsom Free Scholarship, to Mr. J. H. Stewart, of Epsom College.

## SUMMARY OF RECENT MEDICAL LITERATURE, ENGLISH AND FOREIGN.

*Specially compiled for THE MEDICAL PRESS AND CIRCULAR.*

**On the Treatment of Puerperal Convulsions.**—Little (*Journ. Obst. and Gyn. Brit. Emp.*, xvi. 3). Based on the review of 40 cases. Nine cases were post-partum, and 10 women were at term. The following classification is suggested:—(a) Eclampsia in patients before term, 21; (b) eclampsia in patients at term, 10; (c) in patients after confinement, 9. Thirty-two cases occurred between October and March, and it is suggested that the increased incidence at this time of year is consequent upon the difficulty of access to out-house and lavatory, and resulting tendency to chronic constipation. When a definite history could be obtained, severe epigastric pain was always noted. Observations were made in five cases on the coagulation of the blood, and all showed marked decrease to a time varying from  $2\frac{1}{2}$  to  $2\frac{3}{4}$  minutes. The time gradually increased with improvement of the patient. Four, or 10 per cent., of the cases died, which seems to justify some consideration of the treatment employed. One death was due to acute yellow atrophy, and another to cerebral thrombosis, which occurred after the patient had recovered from the toxæmia. After the occurrence of convulsions in 31 undelivered women, 15 were delivered immediately, and 16 underwent treatment before delivery; in 60 per cent. of the former and 62.5 per cent. of the latter the convulsions ceased after labour, which shows that preliminary treatment had little effect in minimising the possibility of convulsions post-partum. Of the 15 patients delivered immediately, 12 live babies were obtained, and, excluding 1 non-viable and 1 dead *in utero*, gives 92 per cent. alive. Of the other 16, 2 cases were admitted with the child dead *in utero*, and 1 child was non-viable. Of the remaining cases, 3, or 23 per cent. of children, were born alive. This shows a difference of 69 per cent. in favour of the child by immediate delivery. It seems that immediate delivery offers the best chance for both foetus and mother. If the child is dead or non-viable, temporising measures are perhaps desirable, as little is gained by delivery in these cases. Cæsarean section was not employed, and should not be seriously considered with eclampsia as the only indication. Vaginal section is only necessary if the cervix is very rigid and undilatable by other means. Forcible dilatation can be effected either instrumentally or by hand, and Harris's method has been most consistently used. The morbidity in these cases has not been any higher than the general average of all cases. When convulsions recur after delivery, or occur during the puerperium, secondary influences are assumed to be at work, the result of disordered metabolism. Suppression of urine being the rule, the skin may be made to act, and the use of hot-air baths has been a great success. Better and more effectual than sweating is bleeding, and it would seem proper to bleed until pallor or weakness of the pulse supervened, usually to 700-900 cc. The third important factor is the administration of large quantities of fluid, 200 cc. per mouth every 20 minutes. F.

**The Induction of Hyperæmia to Determine the Site of Amputation in Gangrene of the Foot.**—Lejars (*Med. Record*, September, 1909, from *La Semaine Médicale*) has used the following method in 22 cases for determining the site in spontaneous gangrene of the foot. Both lower limbs are elevated for a few minutes, and an elastic bandage is applied high on each thigh so tightly as to stop the circulation in the limb. After five minutes the bandage is removed, and the resulting hyperæmia is compared on the two sides. On the sound limb the hyperæmia appears at once, and spreads to the toes. On the gangrenous side the flush may extend to the foot, or even to the limits of the gangrene, but more often it ceases at a variable height

on the leg, or it may not descend below the knee. The level to which this hyperæmia descends marks the level to which the vessels are permeable, and thus indicates the site at which amputation may be performed. Experiments on the cadaver have shown that the permeability of the deeper vessels may be fairly accurately gauged by the limits to which the cutaneous hyperæmia extends. When the colouration ceases abruptly below the patella, it indicated thrombosis of the popliteal, or of both anterior and posterior tibial arteries. Sometimes, while the external surface of the leg remains pale, the redness may extend normally on the posterior and internal aspects of the limb. This shows that the posterior tibial artery has remained sufficiently permeable to justify amputation in the upper part of the leg by a postero-internal flap. In some cases calcification of the vessel made compression impossible, and the test was inapplicable. The procedure appears to be free from danger. No bad effects have resulted in 22 cases in which it has been performed. S.

**Herpes Febrilis on the Fingers.**—Adamson (*Brit. Journ. of Dermatology*, October, 1909) records the cases of four patients who presented this very unusual condition. The first patient was a boy of five years of age who had periodical attacks of an eruption of small vesicles on the thumb. It was thought that this was due to thumb-sucking, to which the child was addicted, but it was found that the eruption of vesicles coincided with attacks of feverish cold, and on one occasion the vesicles appeared on the fore-finger which was not sucked. The second patient was a boy of four years of age who had an eruption of vesicles on the dorsal surface of the second joint of the left index finger. The child was poorly at the time and had herpes at the skin margin of the lower lip. The third patient was a girl of eight years of age, she had during the course of an acute apical pneumonia, an attack of herpes on the dorsal surface of the index finger of the right hand. In the fourth case, the patient a girl, aged nine years, suffered from repeated attacks of herpes on the dorsal surface of the fold between the roots of the first and second fingers of the left hand. K.

**Chorea a Symptom—Not a Disease.**—Swift (*American Journ. of the Med. Sciences*, September, 1909) urges the propriety of looking on chorea as a symptom, as we do jaundice, convulsions or dropsy, and not as a definite disease. The vast majority of cases of chorea may be divided into two classes. In one of these the incoordinated movements are a symptom of some definite infection such as malaria, or infection with the pneumococcus, the bacillus typhosus or the micrococcus rheumaticus. In many such cases there is an accompanying endocarditis and myocarditis, which may result in persistent valvular disease of the heart. The treatment suitable to these patients will depend on the nature of the infecting organism, but absolute rest, physical and mental, is essential to success. In the other group of cases the causal agent is not so definite. The patients are usually young girls between the ages of seven and fourteen years, they are usually in a condition of bad health and anæmia, and have been subjected to some strain, mental or physical. The condition is quite analogous to hysteria occurring in older people. All the treatment necessary for such patients is rest, good feeding and tonics. Under such treatment they improve quickly, and as the nutrition of the central nervous system improves the child regains her lost control over the muscular movements. K.

## NOTICES TO CORRESPONDENTS, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

### SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs 15.12. Messrs. Dawson and Sons are our special agents for Canada.

### ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

BARRISTER-AT-LAW.—Certainly the claim for insurance pay should be made at total incapacity rates under the circumstances you describe. A wound the size of a forin, involving the destruction of the epithelial layer of the skin, is not, of course, in itself dangerous. The risk is mainly that of septic absorption should the dressings slip on movement, and the wound become septic from that or other cause. The proper course is to lie up until the surface is covered with sound skin.

LICENTIATE IN MEDICINE.—The matter to which our correspondent refers has not escaped our notice, and will be dealt with in due course—after further inquiries have been made.

MR. J. PALMER.—Lead poisoning, as an industrial disease, is scheduled for compensation under the Workmen's Compensation Act.

EXPOSITOR.—A full list of references will be found in "Neale's Medical Digest," a copy of which is included in most medical libraries.

A. MARTERTON.—Our correspondent is thanked for his communication; the firm to which he refers has no connection with the well-known medical author of the same name.

WARDER.—Our correspondent has omitted to send his name and address.

NERVOUS INVALID.—Nearly all advertised "electrical" instruments for the cure of nervous ailments are fraudulent. Very often it is impossible to discover any electrical action in them, even by means of delicate testing instruments.

DR. SYDNEY H. HALL.—An early proof of your paper shall be sent you in due course.

MR. R. J. (Barnet).—We agree with the view entertained by our publisher, that it would be inconsistent with the principles we profess to insert your advertisement.

## Meetings of the Societies, Lectures, &c.

WEDNESDAY, OCTOBER 27TH.

HUNTERIAN SOCIETY (17 Finsbury Circus, E.C.).—8.30 p.m.: Clinical and Pathological Evening.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Clinics: 2.30 p.m.: Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 p.m.: X-Rays (Dr. H. Pirie).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m.: Mr. M. Collier: Clinique (Surgical). 5.15 p.m.: Lecture: Dr. C. Riviere: Notes on Tuberculin Treatment.

THURSDAY, OCTOBER 28TH.

ROYAL SOCIETY OF MEDICINE (NEUROLOGICAL SECTION) (20, Hanover Square, W.).—8.30 p.m.: Presidential Address: Professor Sherrington, F.R.S.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m.: Sir Jonathan Hutchinson: Clinique (Surgical). 5.15 p.m.: Dr. F. J. Smith: On the Examination of the Person.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m.: Discussion on the Influence of Mind as a Therapeutic Agent (opened by Dr. C. Shaw).

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynecological Operations (Dr. A. E. Giles). Clinics: Medical Out-patient (Dr. A. J. Whitting); Surgical (Mr. Carson). 3 p.m.: Medical In-patient (Dr. G. T. Chappell). 4.30 p.m.: Lecture: Mr. H. W. Carson: Perforated Gastric Ulcer.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6 p.m.: Chesterfield Lecture: Parvuloculides Due to Tuberculous Toxins—I, Macular; II, Papular; III, Pigmentary.

FRIDAY, OCTOBER 29TH.

ROYAL SOCIETY OF MEDICINE (BALNEOLOGICAL AND CLIMATOLOGICAL SECTION) (20, Hanover Square, W.).—6 p.m.: Presidential Address: Dr. Leonard Williams: To Redress the Balance. Paper: Dr. Eyer: The Hygiene of Naples.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5 p.m.: Prof. A. Keith: Specimens illustrating Malformation of the Abdominal Wall and Irregularities in the Fixation of Viscera. (Museum Demonstration.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m.: Mr. H. Tod: Clinique (Ear).

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinics: Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Operations. Clinics: Medical Out-patient (Dr. A. G. Auld); Eye (Mr. R. P. Brooks). 3 p.m.: Medical In-patient (Dr. R. M. Leslie).

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn Road, W.C.).—3.45 p.m.: Lecture: Dr. Abercrombie: Pharynx and Nasopharynx.

TUESDAY, NOVEMBER 2ND.

CENTRAL LONDON THROAT AND EAR HOSPITAL.—3.45 p.m. Accessory Sinuses: Mr. Stuart Low.

ROYAL SOCIETY OF MEDICINE (THERAPEUTICAL AND PHARMACOLOGICAL SECTION) (20, Hanover Square, W.).—4.30 p.m.: Mr. David B. Lees: The Physical Signs of Incipient Pulmonary Tuberculosis, and Its Treatment by Continuous Antiseptic Inhalations, with the Results of 30 Cases. Dr. H. H. Dale: The Action of Some Diuretics.

## Appointments.

ALLAN, KENNETH BRUCE, M.B., B.S.Durh., Assistant House Surgeon at the Norfolk and Norwich Hospital.

BERGIN, W. MARMADUKE, M.B., B.S.Lond., F.R.C.S.Edin., Assistant Surgeon to the Royal Eye Hospital, Southwark.

COLLIER, JAMES, M.D., F.R.C.P.Lond., Honorary Physician to the Royal Eye Hospital, Southwark.

DODDS, H. BONAR, M.D.Edin., District Medical Officer at St. Vincent, British West Indies.

FRASER, FORBES, F.R.C.S.Eng., Honorary Surgeon to the Royal United Hospital, Bath.

HUTTON, WILLIAM K., M.A., M.B., C.M. (hons.) Glas., Lecturer on Anatomy, Queen Margaret College, Glasgow.

MCHARDY, M., F.R.C.S.Edin., Honorary Consulting Surgeon to the Royal Eye Hospital, Southwark.

FOLLARD, REGINALD, M.B.Durh., M.R.C.S.Eng., Clinical Assistant to the Chelsea Hospital for Women.

STARK, A. CAMPBELL, M.B., B.S.Lond., Assistant Surgeon to the British Skin Hospital.

## Vacancies.

Down County Infirmary.—House Surgeon. Salary £60 per annum, with board and residence. Applications to D. Smith, Registrar.

Nottingham General Dispensary.—Assistant Resident Surgeon. Salary £160, with apartments, attendance, light, and fuel. Applications to C. Cheesman, Secretary, 12, Low Pavement, Nottingham.

Clayton Hospital, Wakefield.—Senior House Surgeon. Salary £120 per annum, with board, lodging, and washing. Application to the Hon. Secretary, Clayton Hospital, Wakefield.

The Guest Hospital, Dudley.—Senior Resident Medical Officer. Salary £100 per annum, with board, residence, attendance, and washing. Applications to the Secretary.

Stamford Hill and Stoke Newington Charitable Dispensary, N.—Assistant Medical Officer. Salary £100 a year, with board and residence. Applications to the Resident Medical Officer.

Lowestoft Hospital.—House Surgeon. Salary £100 per annum, with board, lodging, and washing. Applications to E. S. Norton, Clerk, 148, London Road, Lowestoft.

Aston Union.—Resident Assistant Medical Officer. Salary £120 per annum, together with furnished apartments, rations, and washing. Applications to John North, Clerk to the Guardians, Union Offices, Vauxhall, Birmingham.

## Births.

PENNEFATHER.—On Oct. 23rd, at Deanhurst, Harrow, the wife of C. Maxwell Pennefather, M.B., B.S., of a son.

## Marriages.

JACKSON—ORMEROD.—On Oct. 20th, at St. Matthew's Church, Rastrick, Major R. W. H. Jackson, R.A.M.C., eldest son of Sir Robert Jackson, Knight, C.B., of Sandymount, co. Dublin, to Mary Beatrice, youngest daughter of the late C. J. Ormerod, Esq., of Grearoyd, Rastrick.

JAMES—BRAILEY.—On Oct. 22nd, at the Cathedral, Bombay, Thomas Leslie, son of Frederick James, of South Kensington, to Agnes Helen, only daughter of W. A. Brailey, M.D., of Old Burlington Street, London, W.

## Deaths.

BRICKWELL.—On Oct. 24th, at Pinwell, Slough, the residence of his son-in-law, Mr. John Smith Brickwell, M.R.C.S., L., in his 74th year.

EVANS.—On Oct. 15th, at 43 Cromwell Road, Hove, Henry Evans, M.R.C.S., L.R.C.P., L.S.A., after a long and painful illness.

FREELAND.—On Oct. 22nd, John Ellis Freeland, M.D., C.M.Glas., of 26 Sackville Gardens, Hove, Sussex.

FOMAN.—On Oct. 23rd, at Gate House, East Hoathly, Sussex, Thomas Holman, M.R.C.S., L.S.A., in his 72nd year.

MYERS.—On Oct. 21st, at Kent Cottage, Cleveland Road, Falinge, Henry Reynolds Myers, V.D., late Surgeon-Colonel 19th, late 37th Middlesex (Bloombury), Rifle Volunteers, in his 73rd year.

## NOTES AND COMMENTS.

### Again—the Suffragettes.

THE latest feat of the Amazon Suffragette suggests a steady progress of that hysterical female to the criminal climax. The throwing of tiles from roof-tops upon resident passers-by has been followed by the extremely hazardous crime of destruction by means of corrosive agents. A criminal lunatic of the class that has now grown only too painfully prevalent gained access to the polling booth and threw into the ballot-box a bottle charged with corrosive fluid. The motive of this outrage was presumably to destroy ballot papers, and it may be assumed that the incidental disfigurement of the face of an attendant official merely adds an unlooked-for item of brilliancy to the result. Coming from women who have raised a chorus of indignant fury because of the feeding of some of their number with soft tubes and broth, the disproportion of the whole thing assumes a ludicrous aspect. Tiles from house-tops and vitriol are legitimate weapons on the one side, forsooth, to injure or destroy life, while, on the other, the soft stomach tube and fluid meals are implements of refined torture, in spite of the fact that their mission is to save life. There are still petroleum and dynamite left to these women, who appear to be forsaking the traditions of English womanhood for the ways of the Continental anarchist. The state of mind of a Suffragette who uses corrosive fluid as a means of advertisement of her cause demands careful medical investigation.

### Hop-pickers and Rural Sanitation.

THE backwardness of rural sanitation in the United Kingdom is still the despair of the progressive sanitarian. It constitutes a standing menace to the health of towns, be they never so enlightened and advanced, if they are open to the constant importation of plague and pestilence of various kinds from the country. The agencies whereby the enemy gains an entrance are manifold, albeit in some cases mysterious, and in many others perhaps not even suspected. The instance of milk will occur to every reader as an easy first in the introduction of such scourges as diphtheria, foot and mouth disease, scarlet fever, enteric fever and tuberculosis, into our town populations. Of recent years a reciprocal danger has been recognised in the case of the hop-pickers. Years ago it was shown that a serious outbreak of typhoid fever at Maidstone was due to the infection of the sources of the water supply by infected hop-pickers. Some of the Midland towns are now being vexed by the appearance of that most undesirable malady in their midst. Inquiry has traced the origin of the outbreaks to hop-pickers who have returned from a certain rural district. The correspondent of one local newspaper asks the

Mayor of Dudley to have a personal examination made by the Medical Officer of Health at the incriminated farms. It seems unfair that the rate-payers of a given town should have to pay for the sins of omission of some far-off and petty rural district. A better illustration of the common interest of town and country in public health administration would be hard to find.

### Christian Science.

A CASE in the Coroner's Court at Paddington, on Friday last, illustrated the state of the law with regard to responsibility of attendants on Christian Science patients, which was explained in these columns last week. The wretched victim was an ex-colonel of the Inniskilling Fusiliers, and only fifty-five years old. His malady was varicose ulcers of the legs. Lacking medical help, the disease progressed, acute blood-poisoning supervened, and an attack of syncope brought relief in death. The widow deposed that, after thoroughly discussing the matter, her late husband had throughout declined to see a doctor. It is significant that the Christian Science practitioner is stated to have suggested towards the end, "that as many of the relatives might probably not be Christian Scientists, it would be better to call in a doctor to diagnose the case." When the patient was at the point of death a medical man was called in, and he very properly declined to certify without an inquest. Varicose ulcers in well-to-do patients under scientific treatment do not constitute a deadly disease, and the verdict of the jury that death was accelerated by lack of ordinary medical attention was no doubt a correct one. It was evident that the deceased had never had explained to him the danger in which he lay, and that simple surgical measures would have saved his life. He pinned his faith on Christian Science, and paid the extreme penalty, and the law in such cases, as we explained last week, holds all concerned blameless. To surviving relatives of this unfortunate officer not afflicted with the mental aberration which renders possible belief in a system of sordid miracle-mongering, it can afford little consolation to be assured, as they were by a Christian Science witness at the inquest, "that Christian Science never fails, but the practitioner of the Science sometimes fails through want of understanding"!

### Field Service Rations.

AN experiment just carried out on Salisbury Plain promises to provide some scientific data of the highest importance to the Army, whilst of considerable interest to the medical profession. In order to test the value of the present issue of field service rations, an officer and twenty men were selected to march for twelve days a dis-

tance of at least fourteen miles under service conditions. The men varied between twenty and thirty years of age, and, although all trained soldiers, they were not specially selected for the experiment. They carried the full equipment, which with rifle and 150 rounds of ball ammunition weighed over 56 lbs. No food other than Government rations was allowed; intoxicating liquors were forbidden, and smoking was discouraged. A minute medical examination was carried out at intervals, and the physical results are said to be satisfactory, some of the men losing flesh, but still retaining their muscular strength. The final report, which will include observations of pulsation, blood pressure, and heart affection, will be awaited with interest.

It was impossible for Professor **Professor Osler** Osler, in his address at the opening of the winter session at the London School of Tropical Medicine. School of Tropical Medicine to say anything which would sound novel in the ears of medical members of his audience. The subject has constantly held a prominent place in our columns, and our readers must be well posted up both as regards the scientific position and the practical measures that are possible, and are being carried out in the prevention of tropical diseases. Professor Osler's audience was, however, mainly non-professional, and he evidently succeeded in impressing deeply, not only the American Ambassador, who occupied the chair, but all those who had the privilege of listening to him. Professor Osler pleaded first for central organisation in dealing with the heavy burden of securing health in the Tropics, and pointed to the Sleeping Sickness Bureau, under the Royal Society's auspices, as a model. He then pleaded for funds. He pointed out how vast was the amount of work already achieved by the London School with a capital of less than £40,000. A capital of £2,000,000 would probably suffice for every requirement; and seeing that millions sterling are spent annually on church missions, it seems not unreasonable to ask for adequate endowment for the missions of science.

**The Endowment of Research.** THE Cambridge University authorities announce that Dr. R. C. Brown, of Preston, is continuing for 2 years the scholarship of £150 per annum which he founded in aid of the work of the Committee on Rheumatoid Arthritis and Allied Diseases. The *Times*, whilst dwelling upon the importance of the investigation being carried out, points out that the Committee is much hampered in its work by the want of funds, and suggests that Dr. Brown's example is one that might very generally be followed with advantage. The *Times* does not, however, say anything about the fact that the new knowledge of the disease which in so many directions is proving of such enormous advantage to mankind, is nearly all being accumulated through the self-sacrificing labours of men of science, or through endowments like that bestowed by Dr. Brown—endowments by members of a profession whose source of income is being destroyed by their own generous efforts on behalf of humanity. The State does virtually nothing for the advancement of pure science. The majority of wealthy men have seldom any conception of what is meant by research, and therefore rarely include it within the scope of their benevolence. This ignorance will be overcome only when a knowledge of at least the methods and objects of science is deemed an essential part of a liberal education. At present a great proportion of our boys pass through public schools and universities without the smallest scientific instruction of any kind whatever.

**The Modern "Octopus."** A GLANCE at the annual statistics marshalled and published by the London County Council must cause a sense akin to awe in any but the vain and small. These figures show a population of 7½ millions for greater London, and give the number of the houses at their disposal, together with the area in square miles. Next they detail the seas of water, tons of food, volumes of gas, and other necessary accessories absorbed daily by this multitude. They deal further with their comings and goings, their correspondence and their sewage, the totals mounting to millions, and sometimes to billions. Greater London looms out of this cloud of numbers like some great octopus extracting its nourishment from all quarters of the world; in fact, the compilers are fain to contrast parts with Paris and Berlin. The figures of all three cities which deal with births, deaths and marriages, tell the same tale, but each exhibits a different character. There is a continuous fall in both births and deaths, more marked, however, in the births pointing to a time when the deaths must have the advantage. There are not wanting signs that the German, having joined the rout, will soon overtake his neighbours (the fall being 2 per cent. in Berlin for 1 per cent. in London). The marriage-rate is depressed in London, but has a slightly upward tendency in Paris and Berlin. All these figures, taken with those for illegitimate births, indicate that modified meanings must be applied to such words as vitality, prosperity and respectability, or else what has happened before in history must happen again—viz., civilised man will be enthralled by a slavery caused by the number and variety of his necessities and amusements, which will eventually kill him.

## LEADING ARTICLES.

### SCHOOL CLINICS.

It could never have been the intention of the framers of the clauses of the Education Act, which empowered authorities to carry out the systematic medical inspection of school children, that mere examination and reports, not followed by measures to remedy physical defects and diseases, should be the sole result. The Board of Education, informed by its medical staff, was well aware of the existence of a large group of defects to which children are subject, and which, though undermining health, and often threatening life, do not incapacitate the sufferers from leading the ordinary life of school children. It soon became evident that reports and statistics were of very little practical value, although costing large sums to prepare, and the question next arose as to what agency could be organised for the task of dealing with the evils exposed, and whence the funds were to come to pay for the extra outlay. The question of expense is a vital one in every department of local government. The burden of imperial and local taxation is becoming heavier and heavier. In most districts the education rate has within the past few years risen from a few pence to as many shillings in the pound; burgesses recognise that it is no relief to them merely to shift the impost from local to imperial funds; they have in the end to contribute their share, albeit under another heading. The ratepayer will, however, not for long pay for things that he believes to be of no value; already there is evi-

dence that he is beginning to ask for results of a definite character for the money he spends on medical inspection; he begins to recognise that if the work is ever to become efficient, the same agency that reports on disease must take over also the task of removing it. The solution of the problem—the provision of medical and dental attendance for necessitous children—seems likely to be found in the school clinic; and permission to open such clinics under certain conditions was given in a circular issued by the Board of Education last year. At these clinics the children of the very poor can be attended free, whilst parents able to pay may be, at least, made to contribute towards the expense. The experiments in this direction made by local authorities have proved the practicability of the idea. At Bradford a clinic was opened, and it is stated that of 800 patients passed through during the first six months, 500 were cured. Some clinics have been started with the help of charitable contributions. This has been done at Bow by the London Authority co-operating with the Society for Promotion of Welfare of School Children. During the first six months 80 out of the 141 children were passed as "cured." It is not necessary to specify here the defects and maladies dealt with; there are a vast number that merely call for systematic simple treatment or minor operations. The dental clinic at Cambridge, mentioned on several occasions in our pages, which is also supported partly by the authority, partly by voluntary contributions, has shown what can be done to put an end to conditions looked upon too often as unimportant, although frequently in themselves enough to lower the standard of health to danger-point. The advantage of a clinic in dealing with other simple maladies has been shown in the case of favus. This disease, taken systematically in hand at the London Favus School, was stamped out in three years. It seems evident that, even in the sordid sense of the word, it will pay the State to incur a considerable annual outlay, if by that means it can reduce the burden it now bears owing to the existence of an army of unemployables, incapable in consequence solely of the neglected defects and diseases of childhood.

## CURRENT TOPICS.

### A Medical Hero.

FROM time to time the heart of the medical profession is stirred to its depths by the news of the heroism of one of its fellow workers. The most recent incident of the kind comes from Darran Colliery, about two miles from Bargoed, in South Wales. Early on Friday morning last a violent explosion occurred shortly before the workers on the night shift were timed to leave their work. The ordinary approach to the mine was completely blocked, and the only means of access to the scene of the disaster was through the shaft of another pit four miles away. Soon after the news reached the latter spot, a relief party, headed by Mr. M. Bowen, the general manager, Dr. Turner, the colliery surgeon, and others, descended the shaft and fought their way towards the other pit. One by one they were overcome by the choke-

damp, which was described by one authority as having been the most deadly ever known. Five of these heroes, including the manager, were overcome by the fumes and died. Dr. Turner had a narrow escape. He is described as having repeatedly risked his life in heading the relief party. At length he collapsed, and his followers succeeded in reaching him, but were so overcome by the deadly gas that they were compelled to abandon the doctor to his fate. His death was regarded as certain, but after a while these brave men resolved to return. After walking a quarter of a mile they found Dr. Turner lying in the roadway, still alive. He was carried to a place of safety where oxygen was administered, and he was later conveyed in a comatose condition to Cardiff Infirmary. A deed of this kind deserves the enthusiastic recognition of the whole medical profession, who may well be proud of this South Wales colliery surgeon. The loss of life from the explosion is estimated at twenty-nine, including five rescuers.

### Death from Sea-Sickness.

ALTHOUGH sea-sickness is usually regarded as a subject especially fitted for humorous treatment, it is well to remember that there is also a serious side to the question. Not long ago a man of thirty-five years of age died as the result of sea-sickness during the voyage from Plymouth to Cork. The voyage, which usually takes about a day and a half, was prolonged by a gale, and the steamer was delayed some twenty-four hours. The unfortunate man's sufferings were so great that he appears to have expired while being transferred from the ship to the hospital. Curiously, his former occupation was that of a naval stoker, which he relinquished some time back on account of deafness. It is a well-known fact that even seasoned sailors will at times get sea-sick when exposed to some seas, notably, to the curious roll often experienced in the Carribean Sea. Numerous cases of death from sea-sickness have been recorded. In some cases the untoward result appears to be due to simple exhaustion in otherwise robust persons, in others to rupture of an aneurysm or perforation of a gastric ulcer, while others are the result of shock and exhaustion in individuals who are enfeebled from various organic diseases. It is somewhat curious that medical science has never found a really satisfactory remedy for this distressing malady.

### Sir Victor Horsley and Anæsthetics.

IN his remarks to the students of the London School of Dental Surgery, a week or two ago, Sir Victor Horsley dealt with the relation of dentists to the administration of anæsthetics in a less convincing fashion than is usual with that strenuous thinker. As his views are likely to carry weight from the deserved respect given to Sir Victor Horsley's opinion, it is necessary to inquire whether his argument is quite sound. He was asked, he said, What was a licentiate in dental surgery qualified for? He replied, dentistry, and inasmuch as dentistry could not be carried on without anæsthesia, then it followed that a dentist must be qualified as an anæsthetist. But does it follow? Does Sir Victor suggest that dentistry cannot be carried on unless the dentist himself administers the anæsthetic? This would be very pernicious teaching, if it were not so far removed

from fact. It would be no less absurd to say that the surgeon must be a qualified nurse. Or, to put it further, we might argue that, inasmuch as Sir Victor Horsley's practice cannot be carried on without the aid of railway-trains, it follows that Sir Victor is a qualified engine-driver. On another point, we think Sir Victor's remarks equally open to criticism. In speaking of the administration of chloroform, he stated that as soon as chloroform was given by dose, and not by haphazard open methods, practical safety would be attained. If there is really any evidence to this effect, it should be brought forward, but at present the statement is quite in the air. Moreover, as we have before remarked, there is no reason to believe that chloroform can be administered by dose, for there is no means of knowing how much chloroform is absorbed, even if the percentage in the air be known. However, if Sir Victor be right, a clockwork machine would be the safest of anæsthetics. In our opinion, whenever reliance is placed on perfection apparatus rather than on individual skill and attention, there is grave danger to the patient, and in so far as it is taught that chloroform by any mechanical contrivance can be rendered a "safe" anæsthetic, in so far lives are endangered.

#### The National University of Ireland.

THE lists published in the issue of last week of the appointments made to University College, Dublin, and University College, Cork, almost complete the teaching staff of the new National University. As far as the medical schools are concerned, except for one or two minor appointments, the teaching staffs are now complete. We are glad to congratulate the University on the way in which the appointments have been made, and the fact that the schools are so strongly manned. As far as University College is concerned, it draws most of its staff from the Catholic University School, in Cecilia Street, as was to be expected. The gentlemen who have, under great difficulties, maintained the reputation of that School, will now have a chance of building up a school under more favourable conditions. It is possible that in some of the appointments local influence of the candidates was given too much weight, but, on the other hand, we know that in some cases the Commissioners held out firmly against strong local claims. We wish the University every success in its career.

#### International Conference on Leprosy.

As our readers interested in the question are aware, Dr. Arthur Newsholme and Sir Malcolm Morris were appointed delegates of the British Government to the Conference on Leprosy, held at Bergen, in August last. After the Conference the British and Colonial delegates met, and drew up a statement, and in a Parliamentary Paper issued within the last few days Dr. Newsholme and Sir Malcolm Morris recapitulated the resolutions unanimously adopted in August, and add their own recommendations as to the line of administrative policy needed for the prevention of leprosy within the British Empire. A policy of prevention can only be solidly based on a knowledge of the causation of the disease. In this connection it is interesting to note that, contrary to the strenuous advocacy of Sir Jonathan Hutchinson, the authors

of the Report declare positively that leprosy is not due to the eating of fish, or any particular food; but beyond the statement that the disease is spread by direct and indirect contagion the Report throws no light on its ætiology. The suggestion is made that indirect contagion may be effected by fleas, bugs, lice, and such parasites; and it is pointed out that personal and domestic filth and overcrowding, with close and protracted association between the leprosy and non-leprosy favour the spread of the disease. The Report recommends compulsory notification and segregation in settlements or asylums, and the authors believe that if effectually carried out these recommendations alone will provide the most efficient means of mitigating suffering and assisting recovery, and at the same time will produce a reduction and ultimate extinction of the disease. The Bergen Report had previously affirmed that leprosy was curable, and although no certain remedy is at present available, it is possible that science may in time discover a specific remedy.

#### A Universal Races Congress.

To the making of Congresses there is no end; the latest assumes the title which heads this paragraph, and is to be held in July, 1911. The object of the Congress is officially stated to be the discussion of the larger racial issues in the light of modern knowledge and the modern conscience, with a view to encouraging a good understanding, friendly feeling, and hearty co-operation among races and nations. Political issues of the hour will be subordinated to this comprehensive end, in the firm belief that when once mutual respect is established, difficulties of every type will be sympathetically approached and readily solved. Although the truly formidable cosmopolitan list of professors and men of science who lend their names to this project is calculated to put fear into the heart of a critic, we cannot forbear from setting forth the suggestion that from the scientific point of view the Congress does not seem very practical or very hopeful. In the first place, it may be asked, are there any longer any distinct races to be discovered in Europe, or, at any rate, in Western Europe? As De Foe playfully suggested, it is so very easy to distinguish your Saxon, Danish, Roman, Norman, English. For some thousands of years at least the blood of every European people has been gradually mingling, not only with that of their neighbours, but with that of peaceful and warlike invaders from the remotest parts of the Continent. The British Isles have formed practically the remotest and most difficult of access of all European lands; and yet from what diverse stocks do the present inhabitants spring. Assuming that any pure races ever existed in Europe—an assumption by no means proved—the British of to-day are an amalgam of all those races. Race and nationality are two very different things; and because language, religion, and customs clearly separate the various peoples, it does not at all follow that they can be sorted out and labelled under a truly scientific racial nomenclature.

#### The Foods and Drugs Acts.

MORE than one London daily paper is now giving much space to consideration of the question

of adulteration of foods and drugs. They show very clearly, as we have so often pointed out, that the laws for prevention of adulteration are at present almost complete failures. Their failure justifies John Bright in the opposition he offered to the passing of the first Bills through Parliament. He contended that the evils could never be put an end to until the moral qualities of manufacturers and merchants were so raised that they would no longer be capable of making money by palming off upon the public products, not only faked and inferior, but capable of seriously affecting the health of the consumers. The *Daily News* and the *Daily Express* devote long articles to showing how the laws are evaded, not only with regard to luxuries like wine, but also the common necessities of life, the purity of which is essential to the poor consumer. They show how preservatives are abused, and how, for instance, milk, on its way from the cow to the customer, is, to a vast extent, so dosed with boracic acid as to be converted into a positively poisonous mixture capable of producing deadly results in infants and the aged, whose lives depend upon an adequate supply of the pure article. Our contemporaries do not, however, refer to the fact that the administration of the Acts is in the hands of local authorities, and that, either from parsimony—a desire to keep down the rates—or from self-interest—they are often dominated by small tradesmen, these bodies very commonly ignore the Acts altogether, or, at most, use them in a partial perfunctory fashion. In a great number of urban and rural districts the department of sanitary inspection is defective, there are no officers to take samples, and no provision is made for analysing them, even if they were taken. It is difficult to see what practical effect is likely to be produced by the newspaper articles to which we refer; but it is at least important that the facts should be made widely known among the public.

## PERSONAL.

THE KING has expressed a wish to visit the Lynn Hospital Art Loan Exhibition. As Saturday next, November 6th, is the earliest date on which His Majesty can fulfil the engagement, the exhibition, which was to have closed to-day, will be kept open until that date.

MR. JOHN D. ROCKEFELLER has just set aside a fund of £250,000 in order to fight the "hookworm."

DR. W. A. WINTER, F.R.C.P.I., has been elected Visiting Physician to Dr. Steevens' Hospital, Dublin.

ON October 20th a bronze memorial tablet was unveiled in the chapel of King's College Hospital to the late Professor Lionel S. Beale.

DR. NORMAN MOORE, Physician to St. Bartholomew's Hospital, has been elected to an honorary Fellowship of St. Catherine's College, Cambridge.

ON October 19th Sir T. Clifford Allbutt visited his birthplace, Dewsbury, to open a new nursing home and operating theatre for the Dewsbury Infirmary.

AT the Gwyn Hall, Neath, on October 26th, Dr. J. W. Thomas, the ex-Mayor, was the recipient of a service of plate in recognition of his public work.

MR. ROBERT JONES, a Liverpool surgeon, has won the Liston Prize of £100.

MR. H. T. BUTLIN, D.C.L., F.R.C.S., President of the Royal College of Surgeons of England, has been nominated President-elect of the British Medical Association.

MR. F. E. SMITH, M.P., was formally elected President of the National Pure Food Association, at a meeting held at the Royal Society of Medicine, Hanover Square, on October 28th.

DR. ANTON BREINL, Director of the Runcorn Research Laboratories of the Liverpool School of Tropical Medicine, has been selected to take charge of the newly-formed School of Tropical Medicine in Queensland.

MR. CHARLES BALLANCE, M.V.O., M.S., F.R.C.S., will deliver an address entitled "The Lesson to be Learnt from the History of the Mastoid Operation," at the Central London Throat and Ear Hospital, on November 8th next.

AT Rugby, Mr. T. Johnston, M.R.C.S.Eng., has been presented with a marble clock as a mark of respect and esteem by the members of the Ancient Order of Druids, of which he is a Past Arch, on the occasion of his leaving Rugby to take up a practice in Hove.

DR. J. C. MOTTRAM, Mr. Bryden Glendinning, and Mr. Somerville Hastings have been reappointed to the "Richard Hollins," "Walter Emden," and "Salters' Company" scholarships respectively for a period of one year in the Middlesex Hospital Cancer Research Laboratories.

DR. TURNER, of Deri, who, with commendable pluck, descended the coal pit in South Wales to administer restoratives, is recovering from his exposure to the gases he inhaled. It has also been reported that one of Dr. Turner's shoulders has been dislocated, possibly in the efforts made to save him.

AT a meeting of the Special Election Committee of the Queen's Hospital, Birmingham, held on October 26th, under the chairmanship of Mr. H. F. Keep, Dr. Joseph George Emmanuel was appointed Hon. Physician to fill the vacancy caused by the death of Dr. Foxwell.

DR. JOHN E. JONES, J.P., of Dolgelly, whose death was recently announced in these columns, has left £27,533 personalty; and Dr. Hubert E. J. Biss, Assistant Editor of this journal, whose brilliant career was cut short last month, at the early age of 37, has left personalty valued for probate at £3,731.

DR. JAS. A. LINDSAY, Professor of the Theory and Practice of Medicine, Belfast University, delivered the Bradshaw Lecture, yesterday, at the Royal College of Physicians, London, the subject being "Darwinism and Medicine." We hope to publish this lecture in our next. At the same College, Sir T. Clifford Allbutt will deliver to-morrow the Fitzpatrick Lecture on "Greek Medicine in Rome."

LIEUT.-COL. H. CARR, on arrival from England, is to command Station Hospital, Jullundur; Lieut.-Col. J. V. Salvage, on arrival from England, is to command Station Hospital, Ferozepore; Lieut.-Col. T. Daly is to command Station Hospital, Dalhousie, from March 1st next; Major H. N. Dunn is to command Station Hospital, Dagshai, from March 1st next; Major R. F. E. Austin, on arrival from England, is to command Station Hospital, Jutogh.

# A CLINICAL LECTURE

## ON

### SUPPURATION IN THE ACCESSORY NASAL SINUSES. (a)

By JAMES DONELAN, M.Ch., M.B.,

Chevalier of the Crown of Italy; Laryngologist to the Italian Hospital, London.

#### PART I.

IN selecting suppuration of the accessory sinuses of the nose as the subject of a lecture before qualified and experienced medical men, one has first to consider what aspects of it are likely to be of interest to one's audience. Naturally, one would not attempt to treat so vast a subject fully in a single lecture. On the other hand, in discussing suppuration in cavities so closely associated that one may infect all, and where none can be considered as regards diagnosis without reference to the others, it is very difficult to make a selection. It has seemed to me that my attempt to employ usefully the time at our disposal would be more likely to attain some measure of success if I were to confine myself to setting before you a brief account of the causes, symptoms, and diagnosis of sinus suppuration in general. It would take us too far back in the genesis of chronic suppuration of the sinuses to speak in detail of the acute or sub-acute inflammations that precede it. It may be said at once that the greatest number of these troubles arise from infectious diseases, while those due to constitutional states or extension of neighbouring pathological processes are much rarer.

A long list of these diseases has been contributed by various investigators. It includes influenza, diphtheria, facial erysipelas, croupous pneumonia, enteric, scarlatina, measles, small-pox, cerebro-spinal meningitis, and tuberculosis. Of these only influenza and diphtheria have been proved exciting causes, while on the ground of cases reported by Hajek, of Vienna, and others, it is probable that facial erysipelas may be classed with them. To these should be added attacks of "acute catarrh" of at present unascertained origin.

Influenza must be regarded as the principal causative agent. Linderthal showed in 1897 that the bacillus is almost constantly found in the pus from the sinuses, and very often isolated. Other writers have proved that this organism alone is capable of setting up sinus inflammation and suppuration, and that the other germs so often found—*e.g.*, *D. pneumonia*, *Staph. pyogenes* *an. et alb.*, *Streptococcus*, and *B. coli* are only of secondary importance. The more frequent reports of suppuration in the sinuses in the last 20 years are therefore based not only on improved means of diagnosis, but actually on a much greater amount of material resulting from the frequent recurrence of epidemic influenza.

Of the other organisms I will refer only to the *D. pneumonia* and tuberculosis. The mention of the diplococcus recalls the interesting discussion in which Fränkel championed it as the great cause of sinus suppuration. Fränkel's later researches have shown that the *D. pneumonia* is a common inhabitant of perfectly normal sinuses. He found it in 28 out of 40 perfectly normal cavities, so that it would seem that pathological conditions occur not so much from the mere presence of the organism as from its sudden multiplication.

**Tuberculosis.**—It may be worth while mentioning that, while primary tuberculosis of the mucous membrane of the sinuses is an extremely rare condition, it is somewhat remarkable that Fränkel and Wertheim found sinus inflammation in 33 per cent. of persons who had died of tuberculosis. Tubercle should very likely be regarded as one of the general predisposing causes.

While the preceding are the principal causes of primary inflammation and suppuration of the sinuses, suppuration may also be secondary to other influences. These are, (1) traumatism, and (2) extension of primary diseases from the bony walls.

(1) Trauma of the walls, accompanied by bleeding into the mucous membrane and cavity, affects, as a rule, only the superficial sinuses, frontal and maxillary.

The infectious agent may be conveyed by the injury, or may be already in the sinus, and infect the blood extravasated.

(2) The diseases that may extend from the bony walls include:—

(a) Periosteal and sub-periosteal abscess from dental caries, causing suppuration in maxillary antrum in a large minority of the cases seen.

(b) Syphilis of bony walls.

(c) Primary tubercle of bony walls.

(d) Malignant neoplasms—*e.g.*, empyema of maxillary sinus in connection with cancer of its wall.

It has been a fruitful subject of discussion whether sinus suppuration is more frequently of independent origin, or is always secondary to a nasal affection. The greater weight of evidence, both anatomical and clinical, appears to support the view that it is usually an extension from the nose, and that even where no changes can be observed in the nasal mucous membrane the initial nasal inflammation may have been so slight as to leave no trace.

The most important feature in the mechanism of these diseases is the condition of the outlets, as it almost constantly determines why, in a series of cases of sinus inflammation, some get well spontaneously, while in others chronic suppuration is established.

The following case may serve to illustrate this and some other points:—

A man, æt. 27, seen at the end of December, 1905, had a history of attacks of acute nasal catarrh, with headaches mostly on left side, for several years. Had four attacks of influenza in preceding five years, with severe frontal headache and yellowish discharge from nose, chiefly left side. Two months before he was seen by me had similar influenzal attack; the headache and discharge of thick, yellowish, muco-purulent matter continued, with painful sensation of pressure at root and along dorsum of nose, feeling of tension in left orbit, and almost constant flow of tears from the left eye.

On examination, there were general congestion of the nasal mucous membrane on both sides, yellow muco-purulent discharge in both middle meatus, which recurred rapidly after removal on the left side, not so rapidly on the right.

No recurrence in the olfactory fissure once cleansed. There was a marked difference in the form of the right and left middle meatus. On the right, the middle turbinal was almost normal but for congested coverings; the posterior end of the hiatus semilunaris could be seen. On the left the middle turbinal was much swollen, out-curved, blocking the middle meatus except at anterior end. Between these rhinoscopic findings and the symptoms there was a distinct correspondence; there was also tenderness on percussion of anterior walls of the frontal sinuses, especially the left; on this side there was also sharp pain on pressure of the inner part of upper wall of orbit and over the lachrymal bone. Transillumination showed obscurity over both frontal sinuses and obscurity over left maxillary antrum as compared with its fellow.

(a) Delivered at the Medical Graduates' College and Polytechnic, London, Oct. 5th, 1909.

The treatment consisted in irrigation with tepid alkaline aseptic solutions, and internally, in view of the recent influenza, strong doses of Tr. cinchonæ co. with the decoction, which I have found more useful in post-influenzal conditions than the exhibition of a sulphate of a single alkaloid such as quinine. Within a week the right side got well spontaneously. On the left side, however, the discharge, swelling, and external tenderness continued. As the pain over the left frontal sinus and the orbital tension were increasing, the anterior half of the middle turbinal was removed under local anæsthesia and ischæmia by scissors and snare. The passage of a probe from the hiatus into the infundibulum was followed by a free outflow of pus, and immediate relief of the frontal pain. The probe was next passed into the ostium of the anterior ethmoidal cells for about half an inch, and its withdrawal was followed by a free flow of offensive pus. A test puncture in the inferior meatus of the maxillary antrum showed no pus. The patient made a good recovery, and was seen a few months ago, having had no recurrence of his trouble.

The precise diagnosis in so many of these cases must necessarily be *ex post facto* as regards the removal of part of the middle turbinal, covering the sinus outlets. Before this was done, however, there was good reason to suspect acute influenzal inflammation and suppuration of both frontal sinuses, and probably on the left side implication of the anterior ethmoidal cells as well. Though this is a type of case of almost everyday occurrence, there are several points about it which deserve further analysis as illustrating the mechanism of sinus suppuration, its general tendency to spontaneous healing, and why, notwithstanding that tendency, so many cases become chronic.

Taking first the right side, we learn that spontaneous cure even of such a recessed cavity as the frontal sinus, with its tortuous channel, may take place. It can scarcely be claimed that the irrigation had any direct influence on the abscess other than in favouring its discharge by diminishing the congestion and swelling of the margins of the hiatus semilunaris. That there is nothing extraordinary about such spontaneous cures has been proved over and over again by numerous writers. On the contrary, there is a well-established general tendency to spontaneous recovery with normal structures, otherwise every common cold or influenza would place us in danger of severe sinus troubles or dangerous complications. The practical inference is that expectant treatment should be carried out for a reasonable time if there is no aggravation of the symptoms, before deciding on any operative measures. I have seen many cases, and many have been reported, in which the symptoms disappeared without operation in from four to six weeks.

It is not, however, the spontaneous recovery of the right side in this case that claims our interest so much as the failure to recover without operation on the left. Why do not all cases heal spontaneously? Hajek says:—"The answer to this question illuminates the whole mechanism of sinus empyema." In the vast majority of cases the condition of the outlets determines whether spontaneous healing shall or shall not take place. Other factors there are which shall be mentioned, but this is the most important.

At an early stage of the systematic study of these affections Zuckerkandl recognised the importance of this question, and attempted to answer it on anatomical grounds. He pointed out that, owing to the varying calibre of the infundibulum and ostia of the sinuses, free drainage did not always occur. Moreover, septal deflection, or, as in the case before us, rolling of the middle turbinal outwards on itself, tended to impede the outflow. Further experience has amply confirmed this view, as does the more frequent affection of the maxillary antrum, its mode of drainage in the erect position of the head being less favourable than that of the other sinuses. But while one recognises the work of so many patient investigators, one cannot lose sight of the fact that it is only a tardy application to the nasal accessory sinuses by the general principles of surgery of a principle as old as the days of Hippocrates. The reason is that before the days of local anæsthesia, and especially ischæmia,

progress was practically impossible. How does the obstacle to free drainage occur, and how does it favour suppuration? If we refer to the history of this young man, we see that he had been for a good many years liable to attacks of nasal catarrh, and that on the left side it was frequently associated with symptoms of retention. We may leave the right side out of the question in view of the spontaneous recovery, and regard the attack as an acute empyema of a normal cavity. On the left side the conditions were not normal; there was the middle turbinal curving outwards and obstructing the middle meatus. The mucous membrane of the outer concave side of the middle turbinal is of much looser structure than on the mesial surface, as is that of the middle meatus generally, and is peculiarly liable to cedematous swelling under irritation. It is very likely that he had for years a chronic catarrh of his left frontal sinus, as well as also of his left anterior ethmoidal cells, the acute attacks being exacerbations of this condition. The abnormal secretion caused the oedema, with permanent hypertrophy tending to block the middle meatus more and more with each attack. It was not necessary that the obstruction should be complete. In this case we see the outlets must have been quite sufficient, since the removal of the covering portion of the middle turbinal definitely freed them. There was, however, sufficient obstruction to cause more or less stasis of secretion, and this, by not allowing the mucous membrane to come to rest between the acute attacks, the catarrh became chronic, and a favourable landing-place was prepared for the influenza invasion. Even with patent outlets of good size, stasis of secretion or retention of pus may occur if the secretion is very thick.

We pass now to the grounds on which suppuration of the left anterior ethmoidal cells was suspected. There was a recurrence of pus more rapidly and in greater quantity after cleansing on the left side. There was tenderness over the left lachrymal bone, increased lachrymation, tension in the left orbit, and a feeling of dull tenderness at the root of the nose along the upper part of its dorsum. The difference in the flow of pus on the two sides may be dismissed at once as valueless, as no inference can be drawn from that as to which sinus may be affected. The only symptoms of value were the increased lachrymation, the tenderness over the lachrymal bone, and the peculiar feelings about the nose. The last are discounted considerably by the concurrent symptoms of frontal suppuration, while tenderness over the lachrymal bone and the increased lachrymation remain to suggest the participation of the anterior ethmoidal cells in the process. Tenderness on pressure over the lachrymal bone is only confirmatory when present, as Hajek found it absent in 50 per cent. of ascertained ethmoidal empyemata. A somewhat similar view may be taken of the value of transillumination. In this case both frontal sinuses showed equally dark or equally translucent, and no definite opinion could be formed as a result of the use of that aid to diagnosis in the region where it is most likely to be useful.

With regard to suppuration in the maxillary antrum, it is of little service compared with test puncture in the inferior meatus, owing to the varying conditions of the antrum, and its walls on opposite sides.

Transillumination may be looked on in this connection in much the same light as the non-discovery of the B. tuberculosis in the sputum of a suspected tubercular. It is all very well if it helps to confirm a diagnosis arrived at by other means, but even distinct contrast of translucence is not always evidence that suppuration is present. Cases have occurred where even the normal frontal sinus has been opened through a misleading transillumination.

Another point about this case is the history of repeated attacks. This can generally be elicited on careful inquiry in most cases of sinus suppuration that have become chronic. We have also to notice that a test puncture was made into the left maxillary antrum through the inferior meatus, and that no pus was found.

This showed not only that the suppuration had not its source in the antrum, but that there was a con-

dition termed pyosinus, in which the antrum often serves as a reservoir for the pus from the cavities affected in this case. The normal sphenoidal sinus also occasionally is a reservoir for pus from the posterior ethmoidal cells.

A definite diagnosis as to the source of the pus in suspected disease of the upper sinuses can in general be made only on exposing the ostia by removal of the anterior, or, in the case of the sphenoidal sinus, the posterior part of the middle turbinal.

From this we may also gather some of the criteria that enable one to decide whether or when operative interference is necessary: On the right side no such measures were required. On the left, the permanent tendency to stasis would doubtless have led to chronicity on this or some future occasion if the acute frontal symptoms had not rendered the removal of the obstructing portion of the turbinal necessary.

Apart from the mechanical causes favouring chronicity in this case, there is in many others a general tendency for the acute attack to become chronic. This may be due to various factors, such as unusual intensity of the infection, unusual susceptibility of the mucous membrane, tubercle, syphilis (apart from any definite lesion) of the sinuses, dusty atmosphere, overcrowding, and repeated attacks of inflammation. A history of repeated attacks, as in the case before us, is most frequently obtained with regard to the frontal sinus, as such attacks are rarely overlooked by the patient. It is not so frequently ascertained with regard to the sphenoidal sinus, and least frequently in the case of the maxillary antrum.

The consideration of the foregoing case in illustration of the outlets has induced me to use it in connection with various other points that seemed to arise out of it. I have, as far as possible, avoided comment on the subjective symptoms, as I wish now to say something of the general symptoms of sinus suppuration. These are usually classed as (a) local, (b) general, and (c) those due to complications which I propose to omit, as the complications arising from sinus disease will be fully treated by my friend, Dr. Dundas Grant, in a lecture on October 25th. The local symptoms are those arising from changes in the sinuses themselves, or those caused by the abnormal secretion. They are—(1) headache, (2) secretion of muco-pus or pus, (3) loss of smell, (4) symptoms due to secondary affections of the upper air passages, (5) disturbances of digestion.

(1) Headache, though not always present, is a frequent symptom of acute and chronic sinus trouble. In the latter it arises partly from exacerbations of the chronic inflammation, and is partly a sign of the occurrence of retention from increased obstruction of the outlets. It is usually aggravated by bodily or mental effort, and by the immoderate use of alcohol or tobacco. Its connection with sinus trouble is very often overlooked, and many patients who have suffered from chronic headache for many years, and tried all sorts of "cures" and treatments without effect, have been completely cured by the drainage of an overlooked sinus empyema. Headache is, of course, by no means pathognomonic of sinus mischief, any more than it is of anæmia, nephritis, or even cerebral disease. One has to be cautious as to the prognosis for the headache, even after the successful draining of one or more suppurating sinuses, as, owing to some concurrent affection, the headache may persist as badly as ever. This suggests the reflection that in examining a nose or other individual organ one should never forget the man that owns it, but should at least, in all doubtful cases, make a general examination, or have a report from a reliable colleague. The character of the headache is most variable, but certain types may be recognised.

Headache varies as it occurs in connection with acute attacks of sinus suppuration, or with chronic disease.

(To be concluded in our next.)

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by James Donelan, M.Ch., M.B.,

*Chevalier of the Crown of Italy, Laryngologist to the Italian Hospital, London. Subject: "Suppuration in the Accessory Nasal Sinuses." Part II.*

## ORIGINAL PAPERS.

### HÆMATEMESIS AND ITS SURGICAL TREATMENT,

ILLUSTRATED BY NOTES OF TWO CASES.

By WILLIAM TAYLOR, M.B.DUB. UNIV.,  
F.R.C.S.I.

Surgeon to the Meath Hospital and Co. Dublin Infirmary.

THE treatment of hæmatemesis, the result of gastric and duodenal ulceration, is of such vital importance in many instances that I venture to record the following two cases which occurred in my practice in the early part of the summer.

CASE 1.—Miss E., æt. 50, was taken ill at 3 a.m. with a feeling of faintness, followed soon afterwards by nausea and vomiting. The vomitus contained a quantity of blood mixed with some food *débris*. At 9 a.m. she got a similar attack and vomited about 10 ounces of bright red liquid blood.

Until six weeks before this attack she had always enjoyed good health, but, during these six weeks she complained of indigestion, for which she was dieting herself.

Seen after the second hæmorrhage she was pale and collapsed. Her pulse was about 120 and feeble, though regular. She did not complain of pain. The abdomen was soft and flaccid. There was nothing abnormal to be detected on palpation. There was not a trace of muscular rigidity or induration. The tongue was clean, enlarged, flabby and indented at the sides. She was removed to hospital as soon as possible and at 12 noon the abdomen was opened, as I felt convinced that a recurrence of bleeding of a similar nature would be fatal. The abdomen opened, the stomach seemed normal in every respect. There was not a trace of a chronic ulcer to be seen or felt. The stomach wall was then incised for about three inches, so as to permit the interior to be examined. It was only after a most careful and methodical examination of the entire interior of the stomach by everting it like a glove that we found three small ulcers extending into the submucous coat on the posterior wall, high up towards the œsophageal end. In the centre of the largest of these ulcers the open mouth of the artery from which the hæmorrhage occurred was easily seen and demonstrated to those present.

The vessel was fairly large, and its lumen was about as large as would readily admit the end of a small knitting-needle. A purse-string suture of fine silk was inserted round the ulcer and tied tightly, so as to occlude the artery. A second suture was passed deeply through the wall of the stomach underneath the ulcer, and tied firmly over the artery. The anterior gastric incision was then closed, and a posterior gastro-enterostomy performed in the usual way. The subsequent course of the case was uneventful, recovery was rapid, and the lady is now in the enjoyment of perfect health.

CASE 2 is that of a man, who came under my care at the same time as the lady whose case has just been detailed. He was admitted into the Meath Hospital with a very clear history of

a chronic gastric ulcer. He had been ill on and off for many years and occasionally had coffee-ground vomiting. Some time prior to his admission into hospital he had an exacerbation of pain and vomited almost everything he swallowed; even milk used to cause pain.

He used to relieve the pain by taking bread-soda, and when bread-soda was not available he had recourse to the use of his finger for inducing vomiting. Two days before seeking admission into hospital he vomited a quantity of blood. He certainly looked as if he had lost a considerable amount of blood, for his pallor was most striking. On examination there was well-marked rigidity of the recti muscles above the umbilicus—the right rectus was the more rigid. On palpation over the epigastrium he complained of tenderness, but, there was no induration to be detected on account of the muscular rigidity.

Considering the long and distinct history of ulcer the patient related to us, we determined to perform a posterior-gastroenterostomy upon him as soon as he could be properly prepared for operation.

His teeth were very bad and his mouth was generally in a very septic state.

On the day following his admission, while in the hospital a message was brought to me saying that the man had vomited a large quantity of blood, and was in a very bad state. On going into the ward to see him I found the floor around his bed simply covered with blood and blood clots. The patient was lying in a collapsed state in the bed, and very pale. As soon as everything could be got ready for operation he was brought into the operating theatre and his abdomen was opened in the usual manner.

An indurated mass about as large as a hen's egg, was found extending from the pylorus along the lesser curvature and upwards towards the liver, to which it was adherent. There were adhesions posteriorly as well, so that it was impossible to bring the stomach without the abdominal wound. An incision was made into the stomach just as in the former case. The ulcer was readily seen. It occupied the interior of the indurated mass just mentioned, and was filled up with blood clots. The blood was sponged out, but careful search failed to reveal the vessel from which the hæmorrhage had taken place. As it was presumably a large vessel and as it was likely the bleeding would occur unless the vessel was ligatured, and as it could not be seen it was decided to try and occlude the vessels along the lesser curvature, both left and right of the indurated mass, and thus we hoped to be able to secure the source of the bleeding.

With two fingers of my left hand inside the ulcer to act as a guide, I passed a curved needle threaded with a strong cat-gut ligature, through the entire thickness of the stomach walls to the left of the ulcer. The needle passed through from the anterior to the posterior wall, and the ligature was then tied by my assistant over the lesser curvature. In a similar manner a suture was passed and tied to the right of the ulcer, which was close to the pylorus.

As nothing further could be done directly to arrest the hæmorrhage from the ulcer, the wound into the stomach was closed and a posterior gastro-enterostomy was performed. Morphia was freely given afterwards. The patient vomited some blood on one occasion after the operation,

but otherwise his recovery was uninterrupted and complete. He can now eat anything he likes without pain or discomfort.

Both these cases are interesting, the former because it is the type of case in which we are generally told in text-books, operation is quite unnecessary, as such cases recover completely under purely medical treatment.

From the size of the vessel which was the source of the bleeding in the case of this lady, as demonstrated at the operation, from the rapidity with which the second hæmorrhage followed upon the first—less than seven hours—and from the amount of blood lost by these two hæmorrhages, I am quite convinced that the bleeding would have recurred and that another such hæmorrhage would have been fatal.

The second case is of interest on account of the nature of the procedure adopted to arrest the hæmorrhage. Judging from previous experiences of repeated copious hæmorrhages in cases with histories of old-standing gastric or duodenal ulcers, one is justified in concluding that operation in this case was the means of saving the patient's life, but, whether the result would have been as satisfactory if we had contented ourselves with the performance of a posterior gastro-enterostomy alone, when we failed to detect the actual source of the hæmorrhage, instead of adopting the method we did, must remain open to question.

At all events it added nothing to the risk of the posterior-gastro-enterostomy, while it must, at least, be admitted that it closed two probable sources of hæmorrhage and, having regard to the situation of the ulcer, the odds are greatly in favour of the bleeding having come from the coronary or pyloric arteries, or some of their branches. I have seen five cases of death from hæmorrhage due to chronic ulceration of the stomach. In four of these I saw the post-mortem examination, and saw the opening into the vessel from which the fatal bleeding took place. The fifth case was also verified by post-mortem examination, of which I was informed at the time, but I did not see it myself. I also know of at least seven other cases that died from hæmorrhage from gastric or duodenal ulcers, within the past three or four years. In four of the five cases on which autopsies were made in the Meath Hospital, operation would have been attended by a fair prospect of success if undertaken in time, as the ulcers were easy of access, and with the stomach opened there would have been little or no difficulty in securing the bleeding vessel.

In the fifth case operation could scarcely have been successful. The ulcer was extensively adherent to the pancreas and it was the splenic artery that was opened. It ought to be quite unnecessary for me to add that it is an absolute impossibility to form any opinion when a patient is seen after a hæmorrhage as to whether the bleeding is coming from such a vessel as could be ligatured, or, as to whether the ulcer is so situated that one could get at it or incise it and thus arrest the hæmorrhage.

These are facts that can only be found out by operation or post-mortem examination.

If such a condition as would render an operation futile, so far as the arrest of the hæmorrhage is concerned, and is discovered after opening the abdo-

men, the patient will not be one whit the worse off so far as his chances of recovery are concerned, provided the operation is undertaken in reasonable time, while the physician and surgeon will at all events have the satisfaction of knowing they did what lay in their power to save the patient's life. It may be some consolation to a medical man, who sees a patient after one of these serious gastric hæmorrhages and who postpones operation in the hope that the bleeding will not recur, or delays for a more favourable opportunity, which unfortunately does not present itself—when the post-mortem examination is made and it is discovered that operation could have been of little if any avail in arresting the bleeding.

On the other hand, what would be the feelings of such a man if the autopsy were to show him that the hæmorrhage could have been arrested thereby greatly increasing the prospects of saving the patient's life?

I am convinced that one should not hesitate to operate in a case of severe hæmatemesis or melæna occurring in the case of one who gives a clear history of chronic gastric or duodenal ulceration, provided the patient is not so exanguinated and collapsed as to make it clear that operation in itself must hasten the fatal issue. It is in such a case as that of the lady already detailed that one might perhaps, justifiably, hesitate. There was not by any means a clear history of ulceration in her case, and certainly not a chronic ulcer, still she complained of what she described as "indigestion" for some six weeks, but, there was no sign or symptom of ulceration, save that of slight pain and discomfort after eating—there was no vomiting, and no muscular rigidity.

To sum up, I would urge the advisability of operation in every case of copious bleeding—even after the first hæmorrhage—when there is a clear history to be obtained of chronic gastric or duodenal ulceration. I would also urge the advisability of operating in any case of recurrent serious bleeding, especially if the second hæmorrhage recurred in a short time in anyone who gave a history of even a few weeks' severe indigestion, but who exhibited no other evidence of chronic ulceration. Recurrent slight hæmatemesis of coffee-ground character in connection with chronic ulceration does not necessitate in itself an operation for its arrest. It is, however, an evidence of the presence of a chronic ulcer, which sooner or later may terminate in a fatal hæmorrhage, in perforation or in the development of cancer, and as such it is an indication that an operation which may be termed one of convenience should be undertaken for the cure of the ulceration. Lastly, one should never operate for hæmatemesis occurring in the young anæmic woman, who never exhibited any distinct evidences of gastric ulceration. An operation in such a case simply adds a serious complication to a condition which will readily recover under medical treatment.

### ON REMOVAL OF THE NORMAL APPENDIX.

By H. A. LEDIARD, M.D., F.R.C.S.,

Surgeon to the Cumberland Infirmary.

IN order to facilitate reference to what follows, I make the proposition "that it is a wise and

prudent precaution to remove the healthy or normal appendix in childhood," and I shall endeavour to justify my thesis by the arguments which compose this paper.

To dwell upon the universality of such a common disease as appendicitis, or the number of victims claimed each year, would seem to be a useless task, because all surgeons, physicians and general practitioners have their own practical experience of the frequency of appendicitis in their own practices or in their districts. This practical experience cannot be expressed in figures, for obvious reasons, so that I go to a Blue Book—a source of information which is open to everyone, whether professional or layman. Truth has been stated to be relative rather than absolute, and this holds good for statistics of mortalities, found in the columns of the Registrar-General's Report, which contains an enormous mass of information, which year by year becomes more interesting, accurate, and more practically useful. For example, it was not until the beginning of the present century that the deaths from appendicitis were separately given in the official tables, so that it is now possible to read the number of deaths each year attributable to this cause. The mortality from appendicitis in the last six years has averaged 63 per million in males and 41 per million in females. (a) In both sexes deaths are recorded at all ages, but for the most part the mortality has been highest between the tenth and the twentieth year. Deaths at the age of three to six months and of over 75 years are included. At page 30 of the Report it will be seen that in 1906, 2,144 persons of all ages died of appendicitis in England and Wales. Now, if 2,144 persons died, how many suffered from the same disease and recovered? How many girls, boys, men and women had their school work, their holidays, their employments, or their household duties or pleasures interrupted, spoiled or ruined by an attack of the disease, with or without an operation superadded?

It would be an impossible task to estimate the loss of time and labour by the patients who contract appendicitis and yet make good recoveries, and so estimate the total number of the males and females recovering or dying of this disease. Statistics of operations upon those recovering are not to be had, except partially, in the reports published by the hospitals of the United Kingdom. It is therefore only from the Registrar-General that some idea can be had of the amount of appendicitis in the country. The total amount may be larger or smaller than I care to state, but a day will come when the total number of persons attacked will be better known than it is at present.

What is the value of the appendix to the possessor?

What function does the appendix perform?

Is the appendix missed when it has been removed by the surgeon?

These questions will be answered one by one.

The appendix is of no value to its possessor at all; it represents something wanted during the embryonic stage of the growth of the human species and some other animals, but something not required during the independent life of man; that is to say, that an infant boy or girl has no more use for the appendix than a man of 75 or 85 years of age. It performs no function, or functionates so slightly that the amount is a negligible quantity. No one misses it when it is away, no one knows that he has one until it becomes diseased. On the other hand, it has been proved beyond doubt, before it was ever operated upon, to have been a

(a) See Registrar-General's Report for England and Wales for 1908: p. 461.

trap to catch all sorts of extraneous articles taken by the mouth as food or otherwise. A *cul-de-sac*, a blind alley, in which pins, shot, seeds, concretions, threads, hairs, bits of bone, metal, etc., etc., are caught and imprisoned, and freed only when perforation has been induced by the irritation such foreign bodies create.

Some have imagined that the appendix is in an unexplained manner useful in the human economy, because, being there, it of course has some special value, which we, in our ignorance, are unable to trace. I am not of those holding the good or hidden good of the appendix, because the death-roll seems to speak plainly in the other direction.

The appendix performs no function, is of no value to the possessor of one, and has never in the widest world been missed after it has been removed. What then?

My answer is as follows: The Jews, according to their religion, performed an operation, which Christians in all countries are found adopting of their own instance. Circumcision—an operation done on boy babies for sanitary reasons only—is submitted to, is solicited by parents, and is performed by medical practitioners all over the world. If circumcision is believed to be an improvement on human anatomy, are there not other improvements which may be of rather more general application and done for stronger reasons?

If circumcision is a useful, justifiable, and civilised procedure, the same would hold good for appendectomy, and the more so because the reasons for circumcision do not embrace death, whereas the removal of the appendix would save in one year 2,144 lives, and render safe from attack all the other persons seized with appendicitis, the number of whom it would be impossible to calculate with accuracy.

Perhaps the reader of this paper will receive a shock—very likely he may; but what of the shock if his child, at the age of 5, dies, after a ten days' illness of appendicitis and an operation thrown in? It has been shown that no age, tender or advanced, is exempt from the liability to death from appendicitis, and it has been demonstrated that between 10 and 20 years the highest mortality has been recorded. I therefore counsel the early excision of the normal appendix at the earliest possible age, girls and boys to be dealt with on terms of equality. It is clear that it would be imprudent to take each and every child indiscriminately, at an early age, say, under 12 months, for operation, but a healthy infant could quite well be submitted for normal appendectomy, with a benefit lasting for a lifetime, and the removal of a cause of illness and of death for ever. When one thinks over the valuable lives of men and women, lives valued by friends and relations, no less than by the village, town, city or district in which they have lived, the question of submitting an infant to such an operation as removal of the normal appendix shrinks into insignificance.

But here a point is reached with which it is somewhat difficult to deal, viz., the risk of operation.

It will be admitted at once that the risks of some appendix operations are most grave, because the operation is undertaken when risk to life is already present, and sometimes, indeed often, when the condition is absolutely mortal apart from any operation. These conditions would not be present in normal appendectomy, and, given skill in the use of anæsthetics, given skill in operating, given safety in surroundings, and given a healthy child to start with, it may be said that normal appendectomy is without danger and almost without risk.

The advantages obtained by a successfully-performed normal appendectomy would mean life-

long safety from one of the most troublesome and dangerous forms of disease with which the physician or the surgeon has to deal. Occasionally it has been found that the physician has more progressive ideas than the surgeon who puts on the white gown, and ladies have been met with who are infinitely more progressive and up-to-date than their own family doctors, but there is no surgeon in the wide world with any experience of appendicitis, perforated appendix, gangrenous appendicitis, appendix abscess, local or diffused, who will not be prepared to advise, to recommend, nay, even urge, the reasonableness of getting in front of these unpleasantnesses, to leave alone mortalities, by removing the normal appendix at the earliest possible and feasible age.

In place of a sudden panic, a helter-skelter rush, and the general upset caused by a hasty operation, so often necessitated in appendicitis, a time is selected, a convenient day is chosen, and normal appendectomy is done with the same calmness and deliberation as a vaccination. A day will come when views such as these will be accepted and adopted. In conclusion, a word or two is added about the money expended, the pains taken, the suffering endured, the patience exhibited, upon the vast number of semi-worthless objects which crowd our hospitals. Humanity requires us to be as careful of an ultra-tubercular patient as of the most vegetable forms of lunacy found in our asylums. Go on with the expense, the suffering, the patience and the pains by all means, but why not make a beginning at the other end, why not prevent the possible expense, the suffering, the anxiety, the almost terror of a possible operation at an uncertain period of life, by removal of the appendix when it is sound, when the individual is healthy, and when the procedure can be conducted with an almost absolute certainty of immediate success?

The wound of a normally removed appendix is healed in ten days, and a fortnight's confinement to bed would be the average time absorbed, whereas the wound of an appendix abscess in a favourable case will take, on an average, six weeks.

Less doctoring, less nursing, less worry, less confusion in the two weeks than in the six. Less interruption of business for both sexes, at an operation done at from 6 to 18 months than at an operation from 15 to 30 years of age.

An infant has to be fed, clothed, fresh-aired, taught and doctored. If it has crooked legs they are straightened, if it has a hare-lip or a split palate, these defects are seen to; if the child is ruptured the sac is removed, if there is an ugly nævus on the face this is removed, and so on with a variety of complaints or malformations which do not threaten the life of the child either immediately or in the future, except as regards appearance and possible success or entry into certain walks of life, such as the army, navy, civil service, and a variety of other employments where those having some kind of defect are weeded out.

Probably many surgeons and physicians have thought over the proposal made in this paper, but they may have hesitated to place their views on record, they may have been reluctant to recommend such a "fire-guard" against the risks of appendicitis, and have been contented to allow the risks to go until the individual runs up against them. I am here suggesting a course of action to physicians and surgeons and general practitioners, as the outcome of no little experience in hospital, private, and consulting practice, and my experience is common enough.

As years go on there will be less and less seen of the "too late" cases of appendicitis. Diagnosis will be more quickly made, and surgical interfer-

ence sought for at an earlier moment than it often is at present; the general public will be better informed of the need for early attention to abdominal colic, which may prove the innocent commencement of a fatal perforation or gangrene of the appendix, and, in consequence, call in medical or surgical aid at a more seasonable hour than is sometimes now the case, but all this will not check the attacks of the disease, although the mortality may be reduced. Furthermore, the general public may even go so far as to desire that risk of appendicitis may be removed by the early removal of the appendix, and in this manner meet the surgeon half way.

Finally, there are men who are seated in academical positions of authority, who have the teaching of the rising physicians and surgeons of the next and following decades—what do they say to the proposal?

### QUACKERY LAW.

By G. F. DARKER, M.R.C.S., L.R.C.P., D.P.H.,  
Barrister-at-Law.

THE able articles by Dr. D. Walsh in THE MEDICAL PRESS AND CIRCULAR have drawn attention to the evolution of the law with regard to quacks. The little book brought out recently by the British Medical Association on "Secret Remedies, What they Cost and What they Contain," and referred to by Dr. Walsh, well nigh completes the subject. There remains, however, the question, what is the actual position to-day with regard to patent medicine vendors, the medical profession and the public? There are three distinct societies which one naturally looks to when considering patent medicines and the like. 1, The Pharmaceutical Society; 2, the Apothecaries' Hall; 3, the Royal Colleges of the Physicians and Surgeons.

In practice it appears to come to this:—The Pharmaceutical Society can act if a person holds out that he is a member of the Pharmaceutical Society, and he is not, or if a person sells things that are poisons within the Pharmacy Acts, and he is not properly registered under the Acts. (It has, as has been pointed out, power to advise the King in Council what shall be considered a poison and put in the schedule of the Pharmacy Acts.)

The Apothecaries' Hall can take proceedings against anyone who "compounds and prescribes" medicines for internal or medical use. The Hall cannot, so it has been held, interfere where the treatment has been for a surgical case (bone in toe, for example).

The Royal College of Surgeons of England gives protection to its Fellows and members where liable to be prosecuted for maiming the King's subjects. How far any other surgical qualification gives the same protection is perhaps of academic rather than practical interest.

The Royal College of Physicians of London have rights which they do not use, and possibly could be stopped from using now if they did.

There remains the Public Health Authorities, who might take proceedings under the Food and Drugs Act a little oftener than they do. And, finally, there is left the common law of England, together with the Sale of Goods Act, where an aggrieved party can sue for damages for breach of warranty or fraud, or even prosecute criminally in some cases.

Now, how do the Courts view cases concerning patent medicines? They apply, and rightly apply, the maxim that the plaintiff or prosecutor must prove his case, while they bear in mind the law relating to patent medicines, which seems to be that anyone who procures a licence can retail

patent medicines, but the exemption is restricted to medicines which are protected by letters patent under the Great Seal, and does not apply to proprietary medicines. Sales by wholesale dealers are dealt with under 31 and 32 Vict., c. 121.

### THE ETHICS OF JOURNALISM IN RELATION TO QUACKERY.

By HENRY SEWILL, M.R.C.S. ENG.

TWO episodes in the story of contemporary journalism which have occurred within the past week or so may serve as a text for some observations which perhaps you will allow me to make. The first episode is referred to in the fourth of the series of able papers by Dr. Walsh on "Quacks and the Public Health," printed in THE MEDICAL PRESS AND CIRCULAR of October 20th. Inquiry will, I believe, show that the British Medical Association's authoritative exposure of the character of the quack medicine trade in their pamphlet, "Secret Remedies," has been passed over unnoticed by the vast majority of London and provincial papers, whilst a considerable number, including those whose columns are filled with quack advertisements—papers, moreover, that circulate mostly among the poorer classes—have not only ignored a subject so extremely important to their readers, whose interest they profess to have at heart, but have refused to publish the advertisement of the pamphlet through which the wretched victims of quackery might gain the knowledge they so sadly lack. One can only here repeat the quietly forcible phrases of the *British Medical Journal*. Since the papers alluded to "assign no reason for refusal of the advertisement, the suggestion that it is in fear of offending the quack drug sellers is permissible. It is not an incident of which the British Press can feel proud, but it is one of which the medical profession must take note."

For at least thirty years in your columns, in those of your medical contemporaries, and latterly through the British Medical Association, I have on every occasion insisted upon the fact that the newspaper Press must be held most responsible for the rapid growth of quackery until now, when it has become one of the greatest evils of the kind afflicting society.

I have always pointed out that it is by the aid of newspaper advertisements that quackery flourishes. I divide newspapers in this connection into several classes. There are some that reject fraudulent advertisements; some that insert them innocently; some that insert them carelessly, and very many more that insert them knowingly. The number of those least blameworthy has diminished largely during late years. This is perhaps due to the fact that many have been converted into companies, which as corporations intent upon money-making, are capable of conduct in business which would be repugnant to shareholders if acting individually for themselves. This change in management of papers has led to the stultification of many editors. They have continued to denounce quackery whilst every kind of quack advertisement was being published in their own pages. I speak both of London and provincial papers claiming to stand in the front rank of journalism. I have in my possession a number of leading articles exposing and denouncing quackery in general, and single practitioners, and puffs of the same quackery from the same papers. I would particularly refer to a long and special article published a few months ago in one of the foremost papers of the day. It dwelt upon the injury to the national health arising from the use of quack medicines. It referred to the harm done by sham tonics containing alcohol and narcotics; and described the deadly results which often follow reliance upon quack medicines where organic disease existed, as for example, when an "indigestion cure" containing nothing but a coarse purgative, is relied upon in a case of gastric ulcer. From this same paper I have preserved an enormous advertisement of an "indigestion cure," the character of which had been

more than once exposed in the Law Courts, and the case reported in all the chief papers of the day. I examined a number of copies of the newspapers alluded to and found that they each contained quack advertisements, the cost together of which would be about £200; so that if these issues afforded a fair sample of the quack advertisement department of this paper, its income would amount to at least £50,000 a year from this source. More than a million sterling is being annually expended in quack advertisements. Advertisements in leading papers are often printed in a form which the ingenuous reader must mistake for editorial. This example has naturally led to the demoralisation of many inferior papers, and these now supply without question their endorsement to the false statements of any pretender prepared to pay for sham editorial notices; their pages are crowded with fraudulent puffs in the form of editorial paragraphs. It is not necessary for my purpose that I should do more than briefly refer to the fact that the conduct of many papers, including some claiming to stand in the front rank, has been the same in relation with commercial dishonesty. I have in my possession at least one editorial article from one of the foremost papers of the day, which elaborately exposed and denounced a system of swindling carried on some time ago by a gang of City sharks. It is amazing, but true, that the advertisements of this firm appeared throughout the whole of its existence in the paper I allude to; they were printed in a form more or less closely imitating editorial matter in scores of leading papers throughout the country; they must have cost many thousands of pounds—a measure of the profits made by their authors. The character of the advertisements, as the article in the paper I allude to pointed out, was unmistakable by any man of the world: it could not have been mistaken by astute newspaper managers, who did not scruple thus to take part in plundering and perhaps ruining a great number of simple and confiding people. Incidents of this kind, by no means uncommon, suggest that it is at least necessary to free one's mind from cant when considering that great institution the British Press.

The second of the episodes to which I alluded at the opening of my paper occurred quite recently. A theatre manager wrote to the *Westminster Gazette* a letter which the editor—it matters not to my point whether rightly or wrongly—construed into a threat to withdraw the advertisements of a theatre on the ground that unfavourable criticism of a new play had been published in the *Gazette*. The editor resented this alleged affront; he took it as a suggestion that his paper was to be coerced or bribed in a matter in which independent expression of its opinion was the only honourable course—the suggestion, in fact, that its theatrical criticism should be reduced to the quality of merely paid puffery. The question was taken up by the *Times*. In a clever, characteristic article by its dramatic critic, the leading paper dealt scornfully, sarcastically, and ironically with the idea that great journals could be supposed to have so degraded a standard of honour. The amazing thing about this episode is the ignorance which the editors of the two great papers seem to display with regard to the code of ethics of the bulk of their contemporaries. The *Times* and the *Westminster Gazette* are papers of unblemished honour. They sacrifice a great income by refusing to print certain classes of puffs freely admitted into the majority of papers, even including some which would reject with scorn the suggestion that they did not stand in the front rank of journalism. Every large advertiser is aware that in return for money payment he can obtain either sham or real favourable editorial notices of any enterprise, whether of equivocal character or above suspicion, in the majority of papers; and it is not to be wondered at if occasionally a man of business shows himself unable to discriminate. If really great papers like the *Times* and *Westminster Gazette* wish to safeguard themselves against what in their cases would be gross and gratuitous insults, they must strive to raise the moral standard of the bulk of their contemporaries so that it may no longer constitute a degradation to be asso-

ciated with or confounded with them in the mind of the general public.

## OPERATING THEATRES.

### GREAT NORTHERN HOSPITAL.

UNDIAGNOSED FEMORAL HERNIA.—MR. PEYTON BEALE operated on a labourer, æt. 30, who had just been admitted suffering from acute intestinal obstruction of three days' duration only. He had faecal vomiting, very great abdominal distension, pulse thready and too rapid to count, respiration very laboured, aspect cyanosed. It was therefore evident that operative procedures must be at once undertaken, though from the man's appearance and condition, hope of recovery was exceedingly remote. The patient's history was that two days previously he was seized with sudden pain in the right side of the abdomen, coming on after breakfast; he had not been doing any heavy work; the pain rapidly increased; he had been given numerous purgatives, but the bowels had not acted at all. On examination there was nothing definite to be made out; the inguinal and femoral regions on both sides were very carefully investigated, and, as the pain began on the right side of the abdomen, laparotomy was performed in that region. On introducing the hand into the abdomen and exploring the right side of the pelvis a knuckle of bowel was felt projecting through the femoral ring. By means of gentle traction the bowel was easily reduced, and was then found to be a portion of the ileum, about seven-eighths of its lumen having been forced through the femoral ring, the aperture of which was just large enough to admit the tip of the little finger, so that, strictly speaking, as Mr. Beale pointed out, it should be called a Richter's hernia, although the obstruction was absolutely complete. On withdrawing the strangulated portion from the abdomen, it was seen to be very little changed from its normal appearance; it was slightly injected, but not otherwise discoloured. The abdomen contained a certain amount of slightly blood-stained fluid, and this was rapidly washed out with hot salt solution. The wound was dressed, a small gauze plug being inserted.

Mr. Beale said that he had met with two similar cases at the same hospital during the last year, that is to say, in each one there was a strangulated Richter's hernia, and there was absolutely no evidence of it from the outside; in fact, in each case, all those who had examined the patient, both on admission and before operation, had remarked that whatever the cause of obstruction might be, it was not a strangulated inguinal or femoral hernia. This remark shows very pointedly how in each case the symptoms the patient presented were absolutely typical of strangulated hernia.

The patient, unfortunately, died about three hours after operation, and this, Mr. Beale remarked, shows how extraordinarily severe an acute intestinal obstruction of three days' duration, due to a strangulated Richter's hernia, may be. It should be remembered, he said, that it is not uncommon to find a strangulated inguinal or femoral hernia causing symptoms of acute obstruction, which may be termed comparatively slight, that is to say, not much distension, vomiting not becoming faecal within six or ten days, and the patient in a fairly good condition even at the end of that time.

### KING'S COLLEGE HOSPITAL.

ABSCESS IN THE RIGHT ILIAC REGION DUE TO MALIGNANT DISEASE OF THE CÆCUM.—MR. PEYTON BEALE operated on a man, æt. 30, who had been admitted with an obvious abscess in the right iliac region. The history was of some months' duration, but lately the temperature had risen to over 100, and the man's general condition had become much worse, so he was sent into hospital for immediate operation. The case was assumed to be one of suppurative appendicitis, and the usual operation was performed. A localised abscess was opened, and about half-a-pint of exceedingly offensive pus escaped. The cavity was explored gently with the finger, and its walls every-

where seemed to be smooth. Care was taken not to break down any adhesions or to enlarge the cavity in any way. The wound was irrigated with hot salt solution, and during the process it was evident that only a small quantity of the lotion introduced came out. On observing this, Mr. Beale remarked that he was pretty sure that the case was not one of appendicitis: it was clearly a *B. coli* abscess, and very likely was the result of an infection of a malignant tumour in relation to the colon.

After the operation there was a continued discharge of offensive pus from the wound, and some hours afterwards the lotion which had been lost escaped per rectum. The man steadily got worse, and was never in a fit condition to undergo further operative measures; he soon died, and at the post-mortem it was found that he had a large colloid malignant growth involving the whole of the caput cæci and appendix. The abscess had been in the centre of the growth, and this accounted for the smoothness of the cavity when examined at the time of the operation. The cæcal valves, of course, permitted the fluid to pass into the colon and prevented its regurgitation into the wound which had been made. Several coils of small intestine were found adhering to the colloid mass.

## TRANSACTIONS OF SOCIETIES.

### ROYAL SOCIETY OF MEDICINE.

#### SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD FRIDAY, OCTOBER 22ND, 1909.

Dr. G. A. SUTHERLAND in the Chair.

Two cases of "Anterior Poliomyelitis Involving the Four Limbs" were shown by Dr. A. MANUEL. The first was a child, aged one year and eight months, in whom the condition developed suddenly after a slight injury. The child's temperature when brought to the hospital was 100 F., and all four limbs were paralysed. Some improvement had occurred in the arms since the child was admitted. The second case was a child, æt. 1, in whom the condition resulted from a sudden illness on August 15th, considerable recovery in the arms had already occurred, but there was still complete paralysis of all the extensors of the foot and leg.

A case of "Extra-Capsular Fracture of the Neck of the Femur" in a boy, æt. 6, was shown by Mr. RALPH THOMPSON. The injury had resulted from a fall. The diagnosis was at first very obscure, but a skiagram revealed the true nature of the injury. The case had been treated by extension and Thomas's hip splint.

Mr. MUMMERY said that this injury was very seldom diagnosed in children, but some of the cases of obscure deformity of the hip-joint were very possibly due to a similar injury.

Case of "Congenital Hemidystrophy" was shown for Mr. HOWELL EVANS by Dr. HIGGS. The patient was a child, aged one year and ten months. When only a month old it was noticed that the left side of the tongue was larger than the right, and later that there was asymmetry of the abdomen. At the present time a marked difference can be observed between the sizes of the two sides of the body. It was pointed out that the condition in this case was progressive.

Dr. PARKES-WEBER regarded the case as one of hemihypertrophy of muscular origin.

Mr. LOCKHART MUMMERY reminded the Section of a similar case which he showed two years previously. He considered the condition as being a progressive one, and likely to lead to great deformity.

A case of "Chloroma" was shown by Dr. ESSEX WYNTER. The patient was a female, æt. 3½, showing very marked facial deformity, which had been noticed since the middle of May. The face is

unusually large and bony, with shiny, tense skin over the malar bones, and marked exophthalmia, especially on the right side. The glands about the neck were enlarged. The blood count showed red corpuscles 3,630,000; white, 30,000; hæmoglobin, 56 per cent.; and lymphocytes, 66.2 per cent.

The CHAIRMAN said that he assumed that secondary tumours of the suprarenal capsule could be excluded.

Dr. WHIPPHAM asked where the growths commenced, and Dr. LANGMEAD whether the diagnosis from lymphatic leukæmia had been gone into?

Dr. SPRIGGS mentioned a similar case of his own, and said that he was not convinced by the blood count.

Mr. SYDNEY STEPHENSON recalled a case in which the child was suffering from secondary deposit from suprarenal sarcoma.

A case for "Diagnosis" was shown by Mr. LOCKHART MUMMERY. The patient was a boy, æt. 6½, with a spastic gait and very marked contraction of both tendo achillis. He was only able to walk on the tips of his toes.

Dr. SPRIGGS referred to a similar case which had been regarded as one of hypertonia.

Dr. JEWSDURY pointed out that the case might be one of diplegia, as there were well marked knee-jerks and Babinski's sign was obtainable.

Dr. HIGGS regarded the case as one of spastic paraplegia.

Dr. SUTHERLAND pointed out that there should be in that case some mental defect.

Mr. MUMMERY, in reply, said that there was no evidence of any mental defect.

A communication, entitled "Notes on the Pathology of some Liver Conditions in Childhood with a report of three cases," was made by Dr. A. DINGWALL-FORDYCE.

The first case was that of a child, æt. 7, with sub-acute yellow atrophy of the liver. A year ago the child had an attack of jaundice, and since then had complained of pain in the left side of the abdomen. Seven weeks before death the child began to look ill, and the abdomen was noticed to be swelling. There was diarrhoea and vomiting, œdema of the back, paresis of the left leg and left side of the face, and a squint. Temperature 99 F., pulse 144. The post-mortem showed slight pleurisy and pericarditis. There was some bile-stained fluid in the peritoneal cavity. The stomach was dilated, and in the ascending colon there was an acute tubercular ulcer. The liver was greatly reduced in size and almost flat, and its surface was irregular with well-marked yellow nodules. Microscopic examination showed yellow areas of hyperplasia and much fibrous tissue.

Case 2 was a female, æt. 8, who was admitted to the hospital with caries of the dorsal spine. She died of persistent vomiting a few days after admission. The post-mortem examination revealed a fatty condition of the liver, which weighed 460 grammes.

Case 3 was a male, aged four years and eight months. The child was first seen on account of digestive troubles, and on examination it was noticed that the liver was much enlarged. The child died after an operation, which revealed malignant disease of the liver. Post-mortem examination, the liver was found to weigh 4½ lbs., and to be studded throughout with new growth. A tumour was discovered in the ileum, about one foot from its lower end. The kidneys were enlarged.

A case of "Lympho-Sarcomatosis" was shown by Dr. F. W. HIGGS. It revealed a specimen of an appendix infiltrated with lympho-sarcoma. The kidneys also showed diffuse infiltration with lympho-sarcoma cells.

The specimen from a case of "Acute Inflammation in an Appendix, involuted into the Lumen of the Cæcum, which then formed the Apex of an Intussusception," was shown by Mr. IVOR BACK. The specimen was removed from a girl, æt. 8, by operation, the child recovering. It showed an appendix completely involuted into the cæcum, and markedly inflamed. No explanation as to the origin of the condition was offered.

Dr. WALTER CARR read a paper entitled  
A CASE OF PNEUMOCOCCAL INFECTION IN AN INFANT  
SIMULATING GENERALISED TUBERCULOSIS.

The patient was a child, aged 15 months, who was admitted to hospital with an indefinite history of illness. The case was at first thought to be one of acute pneumonia, but when after several weeks the condition remained unaltered with an irregular temperature it was thought to be one of general tuberculosis. Calmette's test gave a negative result. The child died, and the autopsy revealed no trace of tubercle, but a general pneumococcal infection. There was well-marked pericarditis. The right lung was universally adherent, and the upper lobe showed old unresolved pneumonia, the left lung was also adherent. The peritoneal cavity contained about a pint of semi-purulent fluid.

Dr. SUTHERLAND said he regarded the case as a very unusual one.

#### OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

MEETING HELD (AT THE ROOMS OF THE MEDICAL  
SOCIETY OF LONDON) ON THURSDAY, OCT. 21ST, 1909.

The new President, Dr. G. A. BERRY, in the Chair.

Mr. N. BISHOP HARMAN showed a new retractor for use in excision of the lachrymal sac, also two sisters with symmetrical discoid cataract.

Mr. BROOKSBANK JAMES showed a case with very unusual fundus appearances.

Mr. HERBERT FISHER a case of marginal bilateral keratactasia.

Mr. GRIMSDALE showed a case of retraction of the eyes associated with the act of winking.

#### PRESIDENTIAL ADDRESS.

The PRESIDENT then delivered his address. He was more and more impressed with the truth of the maxim, "*Quot homines tot sententiae*," and it was often educating and inspiring to realise the steps which had led to the great advances, and to get some idea of the manner of thinking and the surroundings of the authors. Nothing was so fascinating as the history of medicine. More than mere rediscoveries could be claimed for present advances; they were new, and were logical deductions from carefully collected observations and experiments, not merely irresponsible speculations. The practical man was an empiric, but now the science of medicine had overtaken and greatly outstripped the art. There were many reasons for treatment lagging behind; practical therapeutics was one of the most imperfect of the arts. Surgery was perhaps least subject to individuality, and it was in that domain that the most advances had recently been made in treatment. But the advances following upon antiseptic surgery had led to an over-confidence in, and too frequent recourse to, surgery, and that tendency was no doubt favoured by the public. That, however, was a mere swing of the pendulum, and would right itself in time. The eye was an organ whose functional activity could be estimated with every refinement. The possibility of suggestion in treatment did not occur to most patients, and one sometimes received most congratulation from those for whom one was conscious of having done the least. There had not been anything commensurate with the advance of general surgery in the sphere of ophthalmology, though there had been greater skill, and the incisions had been cleaner than formerly. The eventual results of operations for cataract were probably the same in all cases. Dr. Berry then entered into a historical retrospect of the methods of operating for cataract, and asked whether finality had yet been reached in the matter. He thought it would be admitted that something better was at least conceivable; there might be cure without operation, and even prevention altogether. And, useful as iridectomy was in the treatment of glaucoma, advance might yet be made in that respect. Nearly all the surgical interference in use for trachoma had their prototypes in ancient times. The treatment which gave the best

results in the more severe chronic cases was now often employed in cases where it became an unnecessary mutilation. Dealing with the incursion of the optician into the realm of ophthalmology, he deprecated that because he could not detect or appreciate underlying eye disease. Dr. Berry went on to speak of the history of the invention of spectacles, as well as of the history of mydriatics, which latter means he thought had been much abused. The advantages of inducing hyperæmia had long been known, and now Bier had placed the matter on a scientific basis. In conclusion, he said he was a believer in a great future for medicine, both preventive and remedial; treatment by sera and anti-bodies and every stimulant form of remedy opened up a vast vista for the future.

#### PEDIGREE CHARTS.

Mr. PRIESTLEY SMITH read two papers: (1) A note on the making of pedigree charts; (2) A pedigree of congenital discoid cataract. The latter almost confirmed Mendel's law.

The PRESIDENT and Mr. NETTLESHIP congratulated the author on his papers.

Mr. NETTLESHIP discussed Mr. Smith's proposals for recording pedigrees, and said the second paper dealt with the largest pedigree of that disease which had ever been recorded.

Mr. R. W. DOYNE said he had observed "Coppock" cataracts for the last 26 years, and 25 years ago he worked out a long series of three generations, all of which were handed over to Dr. Ogilvie when he elaborated his paper. He had formed a rather strong suspicion that as the years advanced the cataract became more dense. In the "Coppock" cases the most advanced of all was one of the three brothers, and the faintest were in young children. One girl, now a schoolmistress, he examined when she was quite a child, and saw her again recently, and he thought the condition had progressed.

Mr. HERBERT FISHER said that recently a case of discoid cataract which was under Mr. Nettleship 16 years ago came to hospital, and there was now no further deterioration in vision.

Mr. TREACHER COLLINS questioned the advisability of using the term discoid cataract for these cases, as this form of cataract was known as the "Coppock." Discoid had been applied to the form of opacity in which the lens was flattened from before backwards.

Mr. PRIESTLEY SMITH, in reply, said it would be very useful if those following up the subject were to give the names of the people, as he believed there was a migration to town, and some supposedly isolated cases might be shown to be connected.

#### LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD OCTOBER 21ST, 1909.

Dr. T. HOLLAND in the Chair.

#### CASES.

Dr. J. HILL ABRAM read a case of "polycythæmia megalosplenica" in a male.

Drs. STOOKES and E. E. GLYNN related a case of ACCIDENTAL HÆMORRHAGE AND CHRONIC URÆMIA, in which *B. proteus* was found. The woman was 28 years of age, and in her fifth pregnancy; had accidental hæmorrhage for eight days at the sixth month. She died 11 days after with symptoms of uræmia. On post-mortem examination numerous small anæmic infarctions were found in the cortex of the kidneys. Cultures made from kidneys and spleen showed *B. proteus vulgaris*. The uterus contained staphylococcus aureus.

Mr. FRANK JEANS read a paper on PERFORATIVE PERITONITIS, with illustrative cases. The paper was based on 10 consecutive cases on which he had operated for perforative general peritonitis. There were 2 cases of perforated duodenal ulcer, and 8 cases of general peritonitis, due to perforative or gangrenous appendicitis. The series included 4 children of 15 years or under. There were two deaths, both being amongst the appendix cases. One child of 11 died of pneumonia

on the fourth day, the post-mortem showing a clean peritoneum, although the symptoms had dated from 4 days before the operation. In one case the patient was 4½ months pregnant, but recovered without aborting. One man died on the 10th day after a small secondary abscess had been opened. In the pregnant case no suprapubic tube could be used to drain the pelvis. Mr. Jeans mentioned a sign which had been present in two of the cases, and which he called "the abdomen moving the wrong way," and attached some importance to it as an early sign of general peritonitis. All the cases were treated with slight modifications of the Murphy method, and Mr. Jeans suggested that possibly the continuous administration of salines might act as a vaccine in appendicitic cases by the absorption of solutions of the products of the *B. coli*, but he left this to the vaccinators and the immunisators.

Mr. PAUL mentioned 15 cases under his care during the last year, of which 4 had died, 2 from perforated duodenal ulcer. In duodenal cases he recommends closure of the pylorus and gastro-enterostomy if the patient can stand it, as he considers death to arise from secondary leakage. He does not interfere unduly with the peritoneum unless very foul, and he washes it through a double tube. He does not use lumbar drainage, but relies upon a long, finely perforated silver tube in the pelvis, and packs down to the perforation. He strongly advocates the continuous instillation of saline under the skin by Barnard's method, the Fowler position, and he thought purgatives desirable.

#### GLASGOW EASTERN MEDICAL SOCIETY.

MEETING HELD OCTOBER 20TH, 1909.

The President, DR. PETER BUCHANAN, in the Chair.

DR. JOHN PATRICK read notes of a case of CONGENITAL HYGROMA OF THE NECK in which he had operated when the child was 13 days old. The tumour was of considerable size, and bulged prominently below the jaw, extending somewhat towards the left ear. It was somewhat doughy on pressure, and there was a globular swelling like a small orange embedded in the neck. Dr. Patrick incised the swelling, which was found to be multilocular, and a quantity of semi-gelatinous fluid escaped. The globular swelling seemed to be a cystic growth springing from the hyoid bone. This was cut away as far as possible. The wound was packed with gauze, and allowed to granulate from the bottom. The reason for early operation was that the tumour was rapidly growing, and causing pressure symptoms on the trachea.

Dr. PATRICK also read notes and produced the P.M. specimen of a case of

#### HERNIA OF THE STOMACH

produced in a female by the handle of a hay fork entering the rectum and finally passing through the diaphragm. The patient entered the infirmary suffering from acute peritonitis with an indefinite history of the accident, and laparotomy was performed within one hour of admission. Death unfortunately occurred within 24 hours of operation.

Dr. PATRICK also read notes of a case of "Hæmorrhage into the Cerebellum" of a man who, previous to death, suffered from headaches and vomiting succeeded by coma. It was thought that this condition was brought about by the shock that the man received from a car accident some short time previous to the symptoms.

Mr. WM. TAYLOR, jun., L.D.S., showed an ingenious device for treating fracture of the lower jaw by an inter-dental splint, and a special clamp being used to fix the displaced fragments.

Dr. JAMES DUNLOP read notes on a case of "Pneumothorax" in a patient who was suffering from early pulmonary phthisis and diabetes mellitus, on whom he subsequently performed paracentesis. There were the usual physical signs of the pneumothorax present, namely, hyper-resonance collapsed lung, displaced heart, bell sound, pulse small and rapid, sugar

in the urine. Dr. Dunlop used a trocar and cannula, and the contained air came out hissing as if under pressure. The patient afterwards stated that his cough was diminished, and also the spit, and instead of remaining in bed as advised he continued to get up every day, and suffered no ill-effects in consequence. The pneumothorax returned, and there was afterwards some suspicions of fluid in the pleural cavity.

#### CENTRAL MIDWIVES BOARD.

MEETING HELD OCTOBER 28TH, 1909.

The President, DR. CHAMPNEYS, in the Chair.

At the special meeting which was announced as preceding the regular proceedings, and the object of which was to consider what action should be taken as to the recommendations of the Midwives Act Committee, Dr. Stanley Atkinson, representing the Midwives' Institute, moved the following resolution:—

#### AMENDMENT TO MIDWIVES ACT.

That any amendment of the Midwives Act, 1902, in the light of the recent report, must provide for:

1. (a) Adequate and certain remuneration of medical practitioners called in, under the Board's regulations, to assist midwives; (b) such payments to be made by the Local Supervising Authority, and not by the Poor-law Guardians. (b.)
2. More definite powers of "suspension" of midwives, whether by the Local Supervising Authority or by the Central Midwives Board. (d4.)
3. Subvention from public funds of midwives who are unable to maintain themselves in sparsely populated and poor districts. (d4.)
4. Revision of the constitution of the Central Midwives Board so as to afford two representatives, to be chosen without restrictions, of the Midwives Institute. (dr.)
5. Systematic purging of the Midwives Roll, in accordance with D3 of the report. (d3.)
6. That the right of delegation of their powers under the Act by the Local Supervising authorities should be revoked. (c.)

The first part of No. 1 was carried unanimously, but the majority voted against the second part, the general feeling being that (a) as the Poor-law already possessed the machinery for paying for medical assistance to midwives, and were able to recover payments on loan, the matter would be settled more speedily if left in their hands. On the other hand, Mr. Atkinson maintained that it was encouraging pauperism, and objected to the stigma of it being laid on families which were only suffering from an unforeseen emergency. The remaining clauses of the resolution were carried.

Miss Paget, representing the Q.V.I.Inst., stated that the Committee of the Institute, in view of the enormous increase of work which would be thrown on them by the recommendation of the Select Committee with regard to the supply and distribution of midwives, urged their claim for a second representative on the Board. A resolution was passed recommending this claim in the event of the Committee's recommendation being carried into effect.

Reporting on the financial position, the Secretary stated that the Board held a balance of £1,282. Some of the Local Supervising Authorities, especially in Wales, had made no response to the demands for fees due; and a resolution was carried to the effect that should a final application fail to elicit any reply, the Board would be forced to take legal action.

A letter had been received from the Lord Mayor of Manchester, forwarding a copy of a resolution passed by the Manchester City Council, suggesting that the Municipal Corporations Association should be represented on the Central Midwives Board.

A letter was read from Dr. G. A. Clarkson, of Caterham, complaining of the conduct of a certified midwife.

It was agreed that Dr. Clarkson be informed that as the midwife was acting at the time of complaint as

a nurse and not as a midwife, the matter is not within the scope of the Board's jurisdiction.

The question of establishing an examination centre at Cardiff is under consideration.

The next general meeting will be held on November 25th; and a Penal Board will take place on December 1st and 2nd, to consider the charges against 30 women cited to appear before them.

## CORRESPONDENCE.

### FROM OUR SPECIAL CORRESPONDENTS ABROAD. FRANCE.

Paris, Oct. 31st, 1909.

#### PLEURISY.

THE treatment of sero-fibrinous pleurisy by hypodermic injections of the pleural liquid has recently come to the front once more, both in France and abroad. This method was first practised by Gilbert, of Geneva, and is known under his name.

Since that time (1894), the method was taken up by different authors. It is thus that Scarpa two years later published an article on auto-serotherapy in pleurisy of tuberculous origin.

In 1889, Prof. Debove, bearing in mind the experiments he had made when injecting under the skin the liquid of ascites, he observed with a rise of temperature phenomena of general reaction, supposing products analogous, if not identical, to tuberculin in the peritoneal effusion had utilised the pleural liquid which he considered might also contain tuberculin.

With a syringe containing 5 cubic centimetres, he withdrew that amount of liquid from the pleura, and immediately injected it beneath the subcutaneous pericostal tissue.

Under the influence of this simple treatment, the patients got rapidly well without the aid of any drug.

However, at the Medical Congress of 1900, Mongour and Gentes made certain reserves as to the results of this method.

Since then several cases were published by Maragliano, Donzello, Fedi, Baccani, Nasetti and others, and more recently Schmitzen, Enriquez, and Gaultier. From the observations of these latter, the decrease of the effusion commenced immediately after the first injection, while the improvement and relief experienced by the patient were never interrupted.

Sometimes the liquid was completely absorbed in from 6 to 10 days; at other times a longer period was required. As to thermic reaction, it was *nil* in many cases, while in others a rise of one or two degrees was observed, but one constant effect of the subcutaneous injections of pleural liquid was an abundant diuresis.

As to the mechanism by which this auto-serotherapy acts in such a beneficial manner, no plausible explanation has been found. In any case the conclusions arrived at by Fedé deserve reproduction: auto-serotherapy seems to be a good treatment of pleurisy.

(a) The method can be easily employed and is absolutely inoffensive.

(b) It can be used not only in the treatment of tuberculous pleurisy, but in other varieties.

(c) It seems to be more rapid in the acute than in the chronic form.

(d) The quantity of liquid to be injected is from two to three centimetre cubes in acute pleurisy, and 5 c.c. in the chronic form.

(e) Thermic reaction is observed more especially in tuberculous pleurisy, affording thus an element of diagnosis. Injection of the pleural liquid produces abundant diuresis.

#### SUPRARENAL INSUFFICIENCY.

Under the influence of lesions of the suprarenal capsules two kinds of symptoms may be observed, said M. Emile Sergent, physician at one of the Paris hospitals: the first, result from irritation of the pericapsular nerve plexus, irradiating lumbar pains on the one hand and general pigmentation of the skin and of the mucous membranes characterising Addison's disease on the other. The other signs of suprarenal

insufficiency consist in troubles of the circulation, of the digestive organs, toxic manifestations and general malaise.

The pulse is small and unstable, varying from one day to another according to circumstances, while arterial hypertension is always observed. These symptoms are accompanied by phenomenon described by M. Sergent as the white streak, to which the author attaches primary importance in the diagnosis of suprarenal insufficiency. He considers it the reverse of the red streak in meningitis. To determine its appearance, the skin of the abdomen is slightly rubbed with the finger, and after a few moments a large white streak appears, remains stationary for three or four minutes, and finally fades away.

Arterial hypertension is accompanied with tachycardia and a sensation of cold and sometimes with a tendency to collapse.

As regards the gastric organ, anorexia is almost complete, with frequent vomiting.

Asthenia is the predominant symptom of suprarenal insufficiency. Dreading the slightest exertion, deprived of all moral and physical activity, the patient is completely prostrated. In a perpetual semi-somnolent condition, he answers questions addressed to him but feebly, receives food with ill grace from dread of the exertion.

During the development of the malady the syndrome may be slow or acute. The former is the clinical expression of the progressive decrease in the function of the suprarenal capsules characterised by melanoderma or colouration of the skin varying from a few brownish spots to a general bronze aspect with the above train of symptoms.

Acute syndrome is provoked by a sudden decrease of the renal capsules, and the symptoms are but an exaggeration of those belonging to the progressive form. They may appear suddenly in patients who had been enjoying good health up to that moment, and frequently mislead the attendant.

The outset is marked by severe lumbar and abdominal pains, cramps, incoercible vomitings, and frequently diarrhoea; the skin is soon covered with clammy sweat, the extremities are cold, the pulse grows weaker, the white streak appears, and the patient falls into collapse or coma.

The treatment reposes essentially on serotherapy, either by the fresh suprarenal glands, or by dry extract. The former may be given in doses of 30 to 40 grains once a day, gradually increased to 100 grains or more, and the latter in six grain doses three times a day, or twenty or thirty drops of adrenalin divided into five or six doses in the 24 hours.

## GERMANY.

Berlin, Oct. 31st, 1909.

At the Naturforscherversammlung, Stabsarzt, Dr. Kuhn, Berlin, spoke on

#### THE STIMULATION OF BLOOD FORMATION.

In all normal as well as abnormal conditions, he said, in which the organism suffers from a certain deficiency of oxygen, there is a compensatory provision for making more and better use of the oxygen of the atmosphere, leading to an increase of the elements of the blood. The drug that increases the blood (arsenic) does not act directly on the blood forming organs, but first of all destroys a portion of the blood. By diminishing the amount of blood an acute demand for oxygen is made, and by it a new blood formation is excited. It is in this way that tuberculin acts. The simplest way of stimulating the formation or building up of blood is therefore the establishment of a sharp demand for oxygen, as by living in a high mountainous region or the wearing of a suction mask.

Hr. G. Levy made an interesting communication to the meeting, the correctness of which, if generally confirmed, will be hailed with great satisfaction, to the effect that amongst the last 1,000 children vaccinated by himself 41 per cent. were breast fed. If so education has begun to bring forth fruit, as it is evidence that the labouring class in Berlin are returning to the natural way of feeding infants. He

closes his observations with the remark that "the infants that were fed naturally were much stronger than the others."

#### THE PRACTICAL YEAR.

The *D. Med. Wochenschr.*, 37/09, contains a proposal for a reform as regards the way in which the last or practical year of the medical curriculum shall be passed. The proposed reforms fall into seven heads, some of which are of sufficient interest to bear transplanting, or at least some consideration.

The first proposal is that the first six months of the practical year shall be passed in a large hospital or University Institution, whilst the last six months the "Praktikant" may be allowed to attend smaller institutions.

2. In the larger institutions the studies of the Praktikanten must be conducted under the supervision of a Praktikanten dozent appointed by government.

3. Every Praktikant must be engaged in practical surgical work for two months.

4. Every medical student, either during his student-ship or during his practical year, must practise midwifery exclusively for one month.

5. The Praktikant must be instructed in nursing duties.

6. Every Praktikant must attend a lecture on social medicine.

The 7th only refers to proof of vaccination.

#### TAR CARCINOMA.

The *Dermat. Ztsch.*, XVI. 2, contains an account of three cases of the above-named forms of cancer by Dr. L. Zweig, of Dortmund. The three patients were all labourers in a coal "briquette" factory. In one case the disease only progressed so far as the repeated return of wart-like growths on the face. After complete destruction by the galvano-cautery these did not return. The second patient did not come under treatment until a coarsely nodular carcinoma had developed in the scrotum. This was extirpated apparently with a permanently good result. The third case on the other hand was characterised by a rather rapid downward course. The patient was a man, æt. 29. He had already had numerous wart-like growths resulting from inflammations of the skin, which had been removed. There were multiple growths on both upper eyelids, the right cheek, the angle of the left lower jaw, and on the scrotum. When first seen they were still movable over the underlying tissues, but microscopically they were undoubtedly carcinomatous. Extirpation of the growths led to apparent permanent recovery; three years after, however, he appeared again with great swelling and painfulness of the right cheek. An incision was made that led to a fistulous passage, which led up to a grumous mass that filled the antrum of Highmore. The loss of substance became greater and greater, and the borders of the disease took on a more cancerous appearance. It did not appear possible to remove all the diseased parts, Röntgen ray treatment did no good, and the man at last died after almost the whole of the right side of his face had been destroyed. The case was one of secondary or metastatic disease of the antrum of Highmore. There had been no return at the spot where the first disease was removed, nor were there any internal metastases. The disease has happily become much more rare than it was formerly. Rigid cleanliness is of vast importance, but where the disease has once shown itself that, in itself, is an evidence of a tendency and of danger if the particular employment is still followed. Why the poor man was not made to make change in his employment when it was so plainly dangerous the writer does not state, although the remarks are concluded by the observation that when once warty growths have become manifest the patient was to be strongly advised to change his employment.

#### AUSTRIA.

Vienna, Oct. 31st, 1909.

#### THE SPECIFIC ANAPHYLACTIC REACTION IN THE BLOOD.

RANZI, in the Serotherapeutic Institute, has been working for some time on this subject, since Pfeiffer and Finsterer announced to the medical world that serum from carcinomatous tumours had a specific

anaphylactic reaction—that is, a particular shock, accompanied with dyspnoea, coma, cramp and paralysis. The method of treatment in their experiments was founded on an intraperitoneal injection in a guinea-pig with carcinomatous serum, and followed in 48 hours by an intraperitoneal injection of the pressed juice from a malignant tumour taken from a cancerous patient, which they affirm gave all the symptoms of anaphylaxia, but the principal of these, they affirm, is the fall of temperature. Their proof rested on experiments with similar animals and serum taken from non-malignant growths, with re-injections where the temperature of the animals did not vary. These authors concluded that carcinomatous serum was a specific for carcinoma where it produces this anaphylactic reaction. Yama Nouchi, and more recently Bauer, confirmed these experiments with tubercular serum. Ranzi endeavoured shortly after the announcement to obtain similar results in the laboratory by acting on animals with the various juices of the human organs and tumours, but failed to obtain that specific anaphylaxia in even guinea-pigs or rabbits. After trying the serum of patients suffering from carcinoma, he made use of an aqueous extract of the tumour, and re-injected after 24 hours, but still the animal gave no specific phenomena. Ranzi therefore concluded that no specific anaphylactic was present, but Pfeiffer and Finsterer maintained that his experiments were faulty. He again publishes a voluminous paper, with experiments of every description, to confirm his objection to the specific anaphylactic. The objections to his first experiments were that he had re-injected within 24 hours, while Pfeiffer's was after 48 hours; secondly, they had used expressed juice, while Ranzi had worked with an aqueous extract of the tumour; and, lastly, that he had not observed the temperature curve after the re-injection. Pfeiffer and Finsterer's chief observation being confined to the rectal temperature after the re-injection of the animal, it was the aim of Ranzi to follow the same experiments closely by intraperitoneal re-injections, as well as intravenous injections, and marking the fall of temperature in the different animals. He selected young guinea-pigs, varying in weight from 200-300 grammes, warming the serum, and injecting it intraperitoneally, and re-injecting some intraperitoneal and some venous. He noted the temperature of the animals, both control and experimental, before commencing, and found the average temperature ranged between 38° and 39° C. For control animals he used solutions of different substances, such as common salt, bouillon, etc., which had different values according to quantity; for instance, 4 c.c.m. of NaCl injected intraperitoneally lowered the temperature 0.7° C., while 10 c.c.m. of the same substance reduced it to 2.2° C.; 4 c.c. of fluid from a hydrocele reduced the temperature 0.6° C.; the same quantity of bouillon reduced it 1.5° C.; 2 c.c. of serum from a horse reduced it 0.7° C., while 3 c.c. of serum from a pig reduced it 4.4° C., and 1½ c.c. of human serum reduced it variously from 0.6° to 4.0° C. Coming to the carcinomatous portion, the fluid from a carcinomatous ascites 4 c.c. reduced the temperature 0.4° C.; expressed sarcoma of the mammae 4 c.c. reduced it 2.7° C.; while the same amount expressed from a sarcoma of the pelvis reduced the temperature 1.8° C. Coming to the re-injection, he divides it into homologous and heterologous; the former is the re-injection after 14 days of a similar fluid, while the latter is the re-injection of a different fluid—i.e., from another animal. He found that 1 c.c. of the serum of the horse injected subcutaneously and followed in 14 days with 1 c.c. injected intravenously, reduced the temperature 0.5° C. to 1.3° C., and after a few minutes acute phenomena and death followed. Again, 1 c.c. of the serum of the horse injected subcutaneously, and followed in 14 days with other 3 c.c. of the same serum injected intraperitoneally, the temperature fell 5.9° C. within two hours, with severe phenomena, but recovery; 1 c.c. of human serum injected subcutaneously was followed in 14 days with 1 c.c. of the same serum injected intraperitoneally with a fall of temperature of 6° C. within one hour, extreme symptoms, and death. In the heterologous,

1 c.c. of equine serum injected subcutaneously and followed in 14 days with a re-injection of human serum intraperitoneally, reduced the temperature  $3.9^{\circ}$  C. within 24 hours, and no peculiar phenomena were present. If 1 c.c. of human serum be subcutaneously injected, and followed after 14 days with a re-injection of 3 c.c. of the serum of a pig intraperitoneally, the temperature will fall  $3.2^{\circ}$  C. in 14 hours, and no special phenomena will be observed. He therefore concludes that the fall of temperature is no specific for the anaphylactic shock.

### HUNGARY.

Budapest, Oct. 31st, 1909.

#### NEW NOMENCLATURE IN OBSTETRICS.

In the address of Prof. Wm. Tauffer, at the Sixteenth International Congress, he remarked that in the gynaecological section of the previous international congress at Lisbon this subject was brought forward for further consideration and investigation, namely, the proposition of Alfredo da Costa, that the Congress should consider working out the unity of nomenclature in obstetrics and the most generally used procedures in obstetrical work. Our Executive Committee busied themselves about the question, and the path and means of the possible solution have been thoroughly weighed. It was, however, perceived that to carry out the problem of this acknowledged ponderous affair, no member of the Executive Committee would be competent, because the unity of the nomenclature could not be worked out either to order or as a commission. The foundation work of this subject could be achieved only by such a scientist, who is just as capable a gynaecologist as he is a qualified philologist, one who is willing to take the work voluntarily, and who has besides the polyhedrous knowledge, and has the necessary time also at his disposal; he has not only to work out the nomenclature, but also to establish the same. Nevertheless, he was convinced that it is incumbent upon the International Congress to recur to such far-reaching and universally important questions repeatedly, in order to keep the matter upon the surface, even when there is no immediate prospect, as on the present occasion, of going into the matter with a view to its solution. We can, however, hope that the right man among the indefatigable workers of our section will be found, sooner or later, who will take the matter up in the proper spirit, and will lay the same as a finished work before the scientific world. That such an able man of the future can reckon on the estimation and the thanks of every member who loves our science, is self-evident.

#### THE VALUE OF CONGRESS WORK.

The usual form of preparation of the scientific contents of the International Congress is to select proper scientific topics and to place them before the Congress in form fit for discussion. To acquit itself of this task the Executive Committee sent out inquiries to the most celebrated specialists among all nations, and requested opinions as to what topics were at present most proper for discussion. From the answers received by the Executive Committee, the topics for discussion were constructed after thorough consideration. The essayists considered it practical not to distribute the subjects among themselves, but to treat the programme in unity. On the contrary, another group of essayists was of the opinion that it would lead better to the goal when each essayist, independently of any other, should select and work out his own essay. They were of opinion that in this way the differential conception and the conclusion arrived at, and the manner of the scientific discussions, would come better to the surface.

In the history of medicine we find many examples for illustration where the weight of certain acknowledged authority held captive the direction of the research, and often for a longer period influenced the same, not seldom for the hindrance of science and suffering mankind. "As an example, I could mention in Germany the fatal mistakes of Dieffenbach (*Oper Chirurgie*, Leipzig, 1848, p. 805) and Scanzoni (*Handbuch*, third edition, 1863, p. 474), which in the 50-60th year of the last century combated the justifi-

cation of ovariectomy; or the wrong position taken by Malgaigne, Velpeau, Trousseau, and Moreau in the same question in 1856-7, when, in the discussions of the Academy of Medicine in Paris, they threw overboard ovariectomy; but in inflammation of the ovaries the iodine injection, with or without drainage, was recommended as exceedingly effective; and covered these dreadful mistakes with considerable statistics. And, lastly, where can we find a better proof for the imprisonment of the spirits of the past of the seemingly unprejudiced world of explorers, than in the history of Semmelweiss; the value and victory of whose doctrine, through the unutterable mistakes of Virchow, were for a score of years delayed?

Now, the question is this: if we had had at that time international congresses, the important questions about ovariectomies, and those about the ætiology of puerperal fevers, could have been brought in about 1860 for discussion; and perhaps the truths of his doctrine would have come to its right twenty years sooner. What an immense number of lost lives lie in this omission.

These and many other examples prove that it will be of great benefit to meet from time to time on the international ground of science. By coming in direct contact with the individual scientists we learn to know the direction of their research and the results obtained. In this way we have the opportunity to compare; the discussions awaken new thoughts in us, they give a severe test in the direction of our own thoughts, and teach us not only to know our good points, but our faults also; thus we free ourselves from the dangerous captivity of a one-sided comprehension.

From this standpoint we hope to receive many benefits from the discussion of the essays.

#### "RECOLLECTION OF SEMMELWEISS.

"Gentlemen,—The milieu in which I have the honour to greet you is—if I may be permitted to say so—that of the spiritual inheritor of my sublime predecessor *ex cathedra*, Philip Semmelweiss, the glorious son of our country, and this city. The ætiology and prophylaxis of puerperal fevers is to-day the common property of the whole civilised world: his discovery is the foundation work for research for all times.

"The Committee of the Semmelweiss monument has erected, from the contributions of physicians the world over, the monument in Elisabeth Square, in this city; and takes this opportunity to render herewith account, and by presenting this souvenir, which each one of you will find in his mail, we discharge our duty.

"On the pedestal besides Semmelweiss is a place still empty, yet it is reserved for the man whose brain will be illuminated with the same Godly spark which enlightened once the mind of Semmelweiss; it is for the man who will discover the therapeutics of puerperal sepsis. Under this device our Congress begins. May the Almighty God bless our work and bring us nearer to our sublime goal."

## FROM OUR SPECIAL CORRESPONDENTS AT HOME.

### EDINBURGH.

PARLIAMENTARY REPRESENTATION OF EDINBURGH AND ST. ANDREW'S UNIVERSITIES.—Sir John Batty Tuke having announced that he does not desire to come forward again as a candidate, Sir Robert Finlay, K.C., has been invited by the Conservative Association to contest the seat at the forthcoming general election, and has agreed to place his services at the disposal of the constituency. Before entering upon the study of law, Sir Robert entered the medical profession, and although he has never practiced, he holds a medical degree. He is a brother of the late Dr. William Finlay, Trinity, whose death took place only a few months ago. Although of late years the member for the Universities has been a practising medical man, the adoption of Sir Robert Finlay is only a return to the state of matters which existed before Sir William Priestley's day, when the seat was regularly held by lawyers, such as Lord Pearson, Lord Kingsburgh, and Lord Stormonth Darling.

**THE LATE DR. CHARLES REID.**—Although for many years Dr. Reid had not been resident in Scotland, the news of his death at the early age of forty-five will be received with wide-spread regret. Dr. Reid was a great footballer in his day—perhaps the finest Rugby forward Scotland ever produced. Even as a schoolboy "Charlie" Reid was selected in 1881 to play for Scotland, and up to the end of 1888 he never missed an international match. On several occasions he captained the Scottish side, and he was for many years captain of the Academicals, who, in the palmy day of his leadership contributed no fewer than five of the nine forwards of the 1886-7 team to the international team. After qualifying, Dr. Reid practised at Selkirk, and subsequently in Swindon, Wiltshire. He had a magnificent physique, standing well over 6 feet in height, and was an excellent shot, a keen fisherman, and a noted breeder of Scotch terriers.

**FIFE COLLIERIES' MEDICAL OFFICERS.**—The following settlement has been arrived at in the dispute as to the question of medical attendance on miners in the Kelty district:—1. Each man employed at the Fife Company's collieries to nominate each quarter the doctor whose services he desires for the next quarter, a list of the names to be sent to the doctor who has been nominated. 2. Each doctor to receive the contributions of the men who nominate. 3. In accident cases requiring immediate attention, the first doctor called must attend until the man's own doctor is available, when the case shall be handed over to him. 4. The question of the supply of medicines to be further discussed after consultation with the man and the Fife Medical Association.

**MEDICAL CURRICULUM AT EDINBURGH UNIVERSITY.**—At the statutory meeting of the General Council of the University, on October 29th, a motion was carried unanimously remitting to the Business Committee to report as to the desirability of procuring by an amending Ordinance, or otherwise, further improvements in the medical curriculum and examinations. In speaking to the motion, Dr. Norman Walker referred the Council to the report approved by the Pathological Club, whose former report and suggestions, the Business Committee stated, were of much assistance toward the framing of the recent ordinance. The report in question is the outcome of a year's hard work by an *ad hoc* Committee of the Pathological Club, which took evidence from the various teachers and others interested, and submitted to a general meeting of the Club a draft report, which was exhaustively discussed on several different evenings. This report has been published in *extenso* in the *Edinburgh Medical Journal*, and as it wisely condescends upon particulars as well as lays down general principles, it is inexpedient to summarise it further than to say that it suggests that a fixed curriculum should be insisted on, and the taking of classes in an unusual order should be discouraged; that the curriculum should be lengthened to the extent of making the student begin in summer instead of in winter, which would add one session of three months; and that in the teaching of the preliminary and scientific subjects of the course the bearing of these on medical practice should be more carefully kept in view than at present. Dr. Harvey Littlejohn, Dean of the Faculty of Medicine, speaking at the meeting of the General Council, said that they had the question of the curriculum under consideration in the Faculty, and that they would welcome any suggestions of the Business Committee.

### GLASGOW.

**GLASGOW FEVER HOSPITALS.**—On account of the prevalence of scarlet fever and diphtheria in Glasgow, a temporary pavilion is being erected at Ruchill, and will be ready for occupation in the course of a few days. The Health Committee also contemplate erecting an observation block of 48 beds at Ruchill, in order to guard against the danger of cross infection.

**QUACKERY RAMPANT.**—The public of Glasgow have been thrown into a state of hysterical excitement over the marvellous cures reported to have been achieved by one bearing the name of Dr. Macaura. One of the largest halls in the City of Glasgow has been taxed to

the utmost to accommodate the people anxious to see and hear Dr. Macaura and his wonderful cures. It is claimed that cases of deafness, old-standing rheumatism and inveterate paralysis have yielded like magic in the hands of this marvellous individual. One patient is reported to have hobbled on to the stage in great agony, and, in his own words, he was so stiff from rheumatism that he could not rise from a chair. It was a surprise for the vast audience to see this patient, after getting about ten minutes' treatment, rise from his chair and move his limbs freely! We are informed that this wonder worker explained to the audience that after all it was a simple matter. He said, "Picture to yourselves a little spring hammer striking on the stiffened joints of muscles with a force equal to a half horse-power." His contention is that his vibratory treatment circulates the blood previously stagnant. Other cases of apparently a crippling nature yielded to his vibratory machine. We are not acquainted with Dr. Macaura's credentials, and, needless to add, we cannot find his name on *The Medical Register*, but evidently he has gained a power over patients that no diploma can confer on an ordinary practitioner.

### BELFAST.

**ALCOHOL IN WORKHOUSES.**—The varying views as to the use of alcohol in workhouse infirmaries have been amusingly illustrated during the past week in two Ulster workhouses. In Lisnaskea, Co. Fermanagh, it was reported that an inmate had drunk ten glasses of champagne, three of Wincarnis wine, and two of brandy in one day, as well as taking two eggs and three pints of milk! One of the guardians inquired upon what day the funeral was held. As opposed to these somewhat generous ideas as to the use of alcohol, we find that at Lurgan Union, the police having sent for the use of the inmates fourteen dozen of porter which had been seized in a shebeen, the same was given to the pigs. Upon what day the funeral obsequies of the pigs were celebrated history does not relate.

**THE PASSING OF THE ROYAL UNIVERSITY.**—Before these lines are in print, the Royal University will have ceased to exist, and it departs unwept, unhonoured, and unsung. It was begotten in deceit and jealousy, and existed most of its days in an atmosphere of bickering and petty intrigue, but it departs in a storm of laughter. The action of the Senate in conferring honorary degrees on themselves all round relieves the situation of all traces of tragedy, and converts it into pure farce. Meantime, the Queen's University of Belfast is growing stronger every day. The classes are filling rapidly, there is keen competition for the scholarships offered, there is wide and increasing interest in its affairs among the citizens generally, and there is every reason to believe that before long we shall have a prosperous, popular, and thoroughly successful University.

## LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

### THE GARDEN CITY MOVEMENT.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—As a lay reader of your valuable paper, I notice that, in common with the noble profession you so well represent, you never forget the maxim, *Salus Populi*, which heads your pages, and I trust that, in continuing to take your share in promotion of social progress in every direction, you will not fail on occasion to give your support to the Garden City movement, which promises to achieve so much towards the physical and moral health of our people. This movement aims at making citizens as well as making cities. This aim has been largely neglected during the past century during the enormous development of our industries, and the crowding together of our millions of increase of population in the hideous workmen's

quarters and slums of our great towns. The people are to a great extent moulded by their environment, and there can be no doubt that not only the stunted frames, but the narrow intellects and the incapacity to appreciate anything beautiful in Nature, art, or literature, which characterise great sections of our populace, are in great measure due to the squalor of the surroundings in which they have been bred. The town planning movement so far has shown what can be done by voluntary co-operation, and through it the question has been placed well within the region of practical politics, as witness the Bill now passing its final stages in Parliament. As the movement advances it cannot fail to associate the poorer classes actively in the improvement of their own condition, and to teach them to understand the real meaning of citizenship. It has been sufficiently proved that all new town areas can be developed in every sense of the words most profitably on Garden City lines—profitably to landowners, profitably to local authorities, and profitably to the individual citizen. The movement must be pressed forward until these facts are fully recognised on all hands, and you, Sir, will, I am sure, give us all the help in your power. I enclose my card, and remain,

Yours truly,

CIVIS.

October 29th, 1909.

# VIAVI REMEDIES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR

SIR,—As a medical profession we should all be grateful to Dr. David Walsh for his recent papers on "Quacks, False Remedies, and the Public Health." To my mind it constitutes one of the strongest and ablest attempts yet made to concentrate attention upon what is, after all, the crucial point of the whole matter—that is to say, upon methods of controlling or checking the evil. I trust the General Medical Council will duly appreciate the mass of facts and suggestions brought together by Dr. Walsh, especially that which insists upon the wisdom of using to the utmost existing legislation. As regards the passing mention of the Viavi methods, and their scathing exposure in the land of their origin—namely, in the American Medical Association's book, "Propaganda for Reform in Proprietary Medicines," it would be well were that volume in the hands of all your readers. On page 233 of the fifth edition it says of Viavi:—"The 'treatment' consisted, and in great part still consists, of prescribing vaginal douches." The article quotes Viavi literature advancing such claims as the limiting of offspring, the curing of a very large proportion of women's diseases, the cure of uterine tumours and of many nervous affections, and the regeneration of wasted testicles.

Now, Sir, it may be of interest to state that the Viavi remedies, to which the above-mentioned scathing exposure relates, are advertised in the public trams of one of our most famous health resorts on the South Coast of England—namely, the conjoined towns of Hastings and St. Leonards. The advertisement announces "free lectures" at an address in the town, and is permanently cut in white letters on a ruby glass ground. Such an advertisement can only serve to disgust medical men who visit the town, as the writer did a few weeks ago, to find the local Council is taking money—in other words, sharing the profits of a method the nature of which has been unfavourably commented upon for years past. Would it not be well for the local authorities of a town that depends mainly for its success as a health resort to submit advertisements of this kind to the medical societies of their district for an opinion? Would it be asking too much for the Councils to obtain copies of the British Medical Association's "Secret Remedies," and of the above-mentioned American book, to be kept for future reference in the matter of advertisements of "cures" or remedies.

I am, Sir, yours truly,

A GENERAL PRACTITIONER.

Oldham, October 30th, 1909.

## REVIEWS OF BOOKS.

### SEMMELEWEIS—A CHAPTER IN THE HISTORY OF MEDICINE. (a)

It is difficult for one at the present day to realise the condition of our hospitals at the beginning of the last century. The bright, cheery wards, spotlessly clean, the thorough ventilation and absence of offensive smell, and the general appearance of comfort of the patients, would, we think, be a source of amazement to the physicians and surgeons of former days could they be brought back to our modern hospitals. One incident in hospital management which occurred in the year 1782 may be mentioned as an illustration of this change. It had been recommended by a committee of investigation as to the condition of the hospital "that no sand be used in any of the wards." The commentary of the medical officers on this recommendation is most suggestive. They said:—"This may be tried, and can be laid aside if not found to answer, but hitherto it was used to soak up the spits and accidental dirt occasioned by the patients." A hospital with the beds full of septic patients, attended by nurses who were generally illiterate, and not infrequently drunk, and the ward floors covered with sand "to soak up the spits and accidental dirt occasioned by the patients," suggests a state of things from which even the most hardened might turn with disgust. We cease to wonder that under such conditions the mortality rate was high; we rather wonder how any inmate escaped with his life. The opening of the nineteenth century saw a marked improvement in the condition of the hospitals of Great Britain and Ireland, due no doubt in a great measure to the preaching of Howard; but on the Continent things improved more slowly, for we are told that when, in 1851, Arnet visited the lying-in hospitals of London, "what appeared to impress him most was this cleanliness and the absence of offensive odour in the wards." From statements such as this we may gather some idea of the condition of the great Vienna Lying-in Hospital in 1846, when Semmelweis entered on the duties of Assistant in the First Obstetric Clinic. At that time the medical classes of Vienna were thronged with students of all nations, who came to learn from such teachers as Rokitsky, Hebra and Skoda, and these students passed from one clinic to another, anxious only to see and learn as much as possible. Thus we are told that men rushed from the post-mortem room, where they had been examining morbid specimens, to the lying-in wards, where they were freely permitted to examine the patients. Ordinary cleanliness, much less disinfection, was rarely thought of. The natural result followed, and of the 20,042 women confined at the First Obstetric Clinic in the six years from 1841 to 1846, 1,989, or 9.9 per cent., died of puerperal fever. In one year, 1842, the mortality rate reached 15.8 per cent. We say now such a mortality was natural under the circumstances, and at the time it was looked on, if not as natural, at least as quite unpreventable. Numerous hypotheses were current as to the causation of this disease, and though they differed widely from each other, yet they had this in common—that they bore no fruit in the prevention of the disease.

It was under these conditions that Semmelweis set himself to solve the problem of puerperal fever, and the methods he adopted and the measure of success and failure which he attained are all set forth by Professor Sinclair in the book before us. Looked at from the beginning of the twentieth century, what a triumphant success, equalled perhaps once or twice in medical history, but never surpassed! Looked at from the point of view of the individual in 1865, with Semmelweis dead in a lunatic asylum, scorned and rejected of many, what a failure! To us, too, the sting of this failure is that it was caused by his own professional colleagues. When we feel inclined to boast of the great profession of medicine, let us think

(a) "Semmelweis, His Life and Doctrine: A Chapter in the History of Medicine." By Sir William J. Sinclair, M.A., M.D., Professor of Obstetrics and Gynaecology in the University of Manchester. 8vo. Pp. x. and 369. Portrait and illustrations. Manchester: The University Press. 1909.

on the career of Semmelweis, and remember that envy, malice, and all uncharitableness, as well as mental blindness, are not the exclusive property of those outside the profession. It is impossible to excuse and difficult even to explain the rejection by the profession of the Semmelweis doctrine of puerperal fever. The explanation which Professor Sinclair gives does not quite satisfy us. No doubt some of the opponents were actuated by malice, and Semmelweis himself did not push his doctrine with that force which his confidence in it would have justified; yet it was widely known and treated with indifference by many who had no cause for jealousy or malice against its author. We believe that the chief factor in the explanation of its rejection is that such doctrines are judged of by the profession by their results, and not by the logical arguments which support them. Even with our present advanced knowledge of bacteriology we know how difficult it is to always be sure of our asepsis, and in the absence of such knowledge we can understand how a few failures would weigh against much logic. It is only by the most minute and persistent attention to detail that consistently good results can be obtained in aseptic surgery, and it is only where faith is strong that such attention will be devoted to detail. Here our works may be justified by faith, but seldom our faith by works.

We must thank Professor Sinclair for the pleasure and instruction which his book has given us, and sincerely hope that this pleasure will be shared by many readers.

#### A SYSTEM OF OPERATIVE SURGERY. (a)

THE Editor says that the work will faithfully reflect the present position of British operative surgery. To ensure this he has secured the co-operation of several prominent British surgeons, who have undertaken to deal with their respective specialities. Promise is also held out "that the work will be up-to-date and useful alike to those who are about to operate for the first time, and those surgeons of experience who desire to keep themselves informed as to the progress that has been made in the various branches of operative surgery." Such a promise, coming from a teacher of Mr. Burghard's reputation, gives hope of seeing a system of operative surgery that would hold a high place in our medical literature. But all operative surgery is not British. There is ample evidence of this in the volume before us, as prominence is given to the classical operations of Dupuytren, Lisfranc, Chopart, Doyen, Esmarch, Farabœuf, Gussenbauer, Hey, Israel, Langenbeck, Le Fort, Texer, Lillenthal, Merzbecker, and numerous others, both on the Continent and the other side of the Atlantic. They have contributed equally to advance surgery and elaborate its operative technique, and so bring about successful results, accompanied with the present low mortality. Volume I. is made up of nine sections. The first is taken up by Lockwood, of Bartholomew's, on "The Principles and Technique of Wound Treatment," which we can confidently commend "to those who are about to operate for the first time." The second consists of two instructive chapters by Captain Houghton, R.A.M.C., on relatively new subjects, one on "Infiltration and Regional Analgesia," and the other on "Spinal Analgesia"; they are both eminently practical. Sections III. to VIII., embracing 501 pages, are from the pen of F. F. Burghard, whose large experience gives authority to his articles on "Amputations"—operations on arteries, veins, and lymphatics, operations on nerves, operations upon muscles, tendons, tendon sheaths, and bursæ, operations for non-tuberculous affections of joints. The operative technique in connection with the surgery of the head is well described, and made very practical; the chapter on the removal of the Gasserian ganglion is specially so, the methods of Rose, Hartley, Krause, Cushing, and Doyen being given their respective places. The illustrations are all that could be desired. T. P. Legg,

(a) "A System of Operative Surgery." By various authors. Edited by F. F. Burghard M.B.Lond., F.R.C.S.Eng., Teacher of Operative Surgery in King's College, London, Surgeon to King's College Hospital, Senior Surgeon to the Children's Hospital, Paddington Green. Four volumes. Vol. I. London: Henry Frowde and Hodder and Stoughton. Price 25 net. Per vol. 36s.

of the Royal Free Hospital, has written Section IX. Four chapters of this are devoted to plastic surgery, which subject has, however, been incompletely treated owing to the omission of certain important operations; these are probably reserved for the forthcoming volumes.

It is to be regretted that large medical works such as this, new editions of which are soon needed, are not published here, as in France, in cheaper form in paper covers.

#### THE MEDICAL INSPECTION OF SCHOOLS. (a)

AT a time when the medical inspection and treatment of school children is so constantly under discussion, Dr. Hogarth's manual should interest a considerable section of the public. It is written in a style which is suitable for the lay as well as the medical reader. No clearer exposition could well have been given of the absolute need for the medical inspection, and of its natural corollary, the medical treatment of school children by the State. We are glad to see that he recommends that the officers in connection with this branch of State medicine should be independent of and not subservient to the Medical Officer of Health, working hand-in-hand with the present Public Health officials, but forming in themselves a new body, whose duty it is to look after the health of the school child, not only from the point of view of those who are interested in Public Health, but also from the point of view of the educationalists. He points out that the school doctor should be well trained both in general medicine and also in the special departments, and should have also studied the normal and pathological growth and development of the child at a children's hospital. Another six months, he thinks, should be devoted to the study of fevers or of mental diseases. Concerning the vexed question of the medical treatment of those found in need of it, the author is no less explicit. After demonstrating in an incontrovertible manner the inability of either existing institutions or the general practitioners to supply what is required, he affirms that the only satisfactory solution to the question is to be found in the establishment of school clinics, at any rate in the larger towns and cities. Dr. Hogarth does not theorise without foundation. He has had considerable experience in school medical inspection in London, and is well acquainted with the needs of the school child. The reader who expects to find in this book the details of school hygiene such as the construction of school buildings or the proper slope of desks, will be disappointed, but in its place he will find well-thought-out if somewhat idealistic schemes concerning medical inspection and treatment of school children, and an outline of the present plans in vogue in the metropolis and elsewhere. In short, we regard this work as an important contribution to a great question, and would commend it to all those who are interested in the subject.

#### FOODS: THEIR COMPOSITION AND ANALYSIS. (b)

THIS well-known work has continued to grow, and it represents the result of many years' experience on the part of the authors. The book as a whole is excellent, but we should like to call attention to what we consider to be some of the deficiencies of the present edition. The authors adhere to the word "proteid" long after everyone else has come to use "protein," and we think that most bacteriologists now follow Chester in calling the organism formerly known as *B. enteritidis sporogenes*, *B. Welchii*. A paragraph on page 309, which is headed "Skim Milk Cheese," makes no reference whatever to this article. No mention is made of

(a) "Medical Inspection of Schools." By A. H. Hogarth, M.B., B.Ch.Oxon., D.P.H. Oxford University Press: Henry Frowde London: Hodder and Stoughton.

(b) "Foods: Their Composition and Analysis." A Manual for the Use of Analytical Chemists and others. By Alexander Wynter Blyth, M.R.C.S., Barrister-at-Law, Public Analyst for the County of Devon and the Borough of St. Marylebone; and Meredith Wynter Blyth, B.A.Cantab., B.Sc.Lond., F.I.C., Public Analyst for the Boroughs of Brighton and Eastbourne. Sixth Edition. Revised, enlarged and rewritten. Pp. 616 and xxv. London: Charles Griffin and Co., Ltd. 1909. Price 21s.

Richmond and Miller's or Cribb and Arnaud's processes for the estimation of boric acid in milk, while research connected with the question of the identity of human and bovine tubercle bacilli is left at the appointment of the Royal Commission in 1901. We have found no mention of the aldehyde figure of milk, or of Buddha's process for preservation. The authors differ from most bacteriologists in that they have not apparently adopted the procedure for the bacteriological examination of water, as recommended by the Committee of the Royal Institute of Public Health. If the procedure on page 561 for the preparation of agar plates be followed, the worker will wonder what on earth is meant. A very antiquated method for "standardising" nutrient broth is given (p. 561), in fact, we do not think we are doing the authors an injustice when we say that the section on the biological examination of water needs very careful revision. As it stands, it greatly detracts from the value of an otherwise most useful book.

#### ROYAL ARMY MEDICAL CORPS. (a)

SEEMING that the examinations for promotion in the ranks of the Royal Army Medical Corps are of a searching character, and likely to become more and more so, Captain Beggs' book appears opportunely, and will be of much assistance to the men of his corps. The very fact of the book having reached a second edition within three years shows its usefulness. Moreover, in this second edition, the contents have been brought well up to date in accordance with the latest regulations, official text-books, and Army orders which not infrequently amend, cancel, or add to something previously promulgated. The several parts of this well-got-up work deal with promotion to corporal, additional for promotion to sergeant, and further advancement to the grade of staff-sergeant. Besides, there are instructions of qualification for a certificate in semaphore signalling, now authorised as part of the instruction in field training of the Medical Corps, and, lastly, hints to young non-commissioned officers in clerical and other duties in a military hospital, which in themselves throw a responsibility of their own on the clerk section. The illustrations of surgical instruments and appliances have been well executed, and the chapter on the Regulations contained in the pay warrants, as also the instructions relating to pay duties and payment of the Corps are creditable. The questions and answers on various subjects embraced in the examinations for promotion are concise and comprehensive—in short, Captain Beggs' book shows care and labour in its compilation, and, while commending it, we wish it success.

#### GENERAL SURGERY. (b)

THE scope of "General Surgery," by Ehrich Lexer, requires some explanation. It is briefly and adequately described in the sub-title as "A presentation of the scientific principles upon which the practice of modern surgery is based." The work deals with the fundamental conceptions which apply to all fields of surgery, with the idea that when these are thoroughly mastered by the reader, their application to special surgical conditions will become easy and intelligent.

The volume is divided into seven parts. Part I. treats of wounds, aseptic technique, anaesthesia, and the principles of plastic operations. Parts II. and III. give an account of wound infection and necrosis; and Parts IV. and V. of injuries and diseases of tissues. Parts VI. and VII. are devoted to tumours and cysts. The appendices deal with the direct transfusion of blood, and the therapeutic inoculations of dead bacteria. The book contains 449 useful figures and pictures, a few of which are coloured. Most of them

(a) "Guide to Promotion for Non-Commissioned Officers and Men of the R.A.M.C." By Capt. S. T. Beggs, R.A.M.C., Reserve of Officers. London: Gale and Polden. 1909.

(b) "General Surgery." By Ehrich Lexer, M.D., Professor of Surgery, University of Königsberg. Translated from the German and edited by Arthur Dean Bevan, M.D., Professor of Surgery, Rush Medical College, Chicago, and Dean Lewis, M.D., Assistant Professor of Surgery, Rush Medical College. Pp. 1041. London: Sydney Appleton and Co. 1908.

are retained from the German edition. They suitably illustrate bacteriological and pathological slides, and the clinical and X-ray appearances of various conditions. There are also two coloured plates.

The volume is an up-to-date account of the science of surgery by a German author. The English translation contains such additions and alterations as seem desirable for completeness. Special chapters have been added on blastomycosis, on the blood examination in surgery, and on Wright's vaccine treatment.

"General Surgery" discusses many important and interesting points in the rationale of treatment, which are not usually given in such detail in most text-books. This feature alone would justify us in recommending it to the profession. The study of the work will be found both profitable and pleasant reading.

#### POISONING BY ARSENIURETTED HYDROGEN OR HYDROGEN ARSENIDE. (a)

THE subject of arsenic gas poisoning has received but scant attention from writers on toxicology. This is the more surprising when the extremely poisonous nature of the gas and the many trades and professions that must from time to time encounter it is considered. Although neglect of the subject is to be regretted, it is a matter for a kind of congratulation that such neglect has been noticed by the author. For this monograph deserves to be noted as an excellent specimen of thorough work. Two cases came within the experience of the writer, and he commenced a thoroughly conscientious examination of the literature of the subject, and studied the ways in which the gas was produced and detected, its effects, diagnosis, treatment and prevention. One hundred and twenty cases are so fully recorded that the account takes 104 pages. Most medical men who read this book will be surprised to find how great a variety of occupations are involved, and those interested in industrial diseases cannot afford to neglect this work. The book was badly needed, and the need has been admirably satisfied.

#### THE CURE OF RUPTURE. (b)

DR. MILLER, at the end of his little book on the "Cure of Rupture by Paraffin Injections," reports ten cases he treated by this method in 1905 and 1906. Cure resulted in each case, but apparently no patient was personally examined more than four months after the operation. The history in Case 8 concludes as follows:—"Personal communication one year later, making final payment for operation, patient cured and grateful."

The author has taken considerable pains to detail the technique, and makes clear the disadvantages of the procedure. Paraffin injection for the cure of hernia is only applicable where the protrusion is small, and, as the writer admits, the paraffin may give rise to trouble and discomfort. The book is instructive, but hardly convincing as to the efficacy of this method of treatment.

## LITERARY NOTES.

THE author of "Children of the Poor" has written a little book which should be welcomed by all who are interested in the betterment of the social conditions of the slum child. As medical officer to the Bournemouth Education Committee, and late Resident Medical Officer to the Cardiff Union Workhouse and Hospital, Dr. A. Davies Edwards writes as one who has seen and deplored the great amount of unnecessary misery and suffering which the children of the poor have to endure. Each of the earlier chapters is a clever and sympathetic little sketch of some aspect

(a) "Poisoning by Arseniuretted Hydrogen or Hydrogen Arsenide: Its Properties, Sources, Relations to Scientific and Industrial Operations, Symptoms, Post-Mortem Appearances, Treatment and Prevention." By John Glaister, M.D. Glasgow, L.R.C.P. and S. Edin., D.P.H. Cantab., F.R.S.E., Examiner in Forensic Medicine and Public Health for Diplomas in Medicine and Surgery, and for Diplomas in Public Health of the Scotch Triple Colleges. Pp. 279. Edinburgh: E. and S. Livingstone. 1908.

(b) "The Cure of Rupture by Paraffin Injections." By Charles C. Miller, M.D. Pp. 81. Chicago: Oak Printing Co. 1908.

of child life in the slums, and later the means of improving these conditions is dealt with from the point of view of the well-being of the nation, and on the broader basis of humanity. The book is delightfully written, and contains several good photographs.

\*\*\*

THE "Catechism Series" of Messrs. E. and S. Livingstone is well known to medical students in the *travail* of examinations as a most helpful way of assimilating that knowledge that is to ensure a pass. Part II. of "Chemistry (Inorganic and Organic)" has appeared in a new edition, revised and enlarged, to carry on the beneficent task of keeping the student hopeful of success at the beginning of his student days.

\*\*\*

LAST year we were treated to two volumes of "The Chemical Constitution of the Proteins," by R. H. Aders Plimmer, D.Sc. An addition to the same series ("Monographs on Biochemistry") on "The General Character of the Proteins" (2s. 6d. net), is contributed by S. B. Schryver, Ph.D., D.Sc., Lecturer on Physiological Chemistry in University College, London. A fourth volume on "The Vegetable Proteins," is by Thomas B. Osborne, Ph.D. (3s. 6d. net). The authors are well known as authorities on the proteins and their work will be read with interest by chemists and physiologists. These volumes are published by Messrs. Longmans, Green and Co.

\*\*\*

WE are promised during the next few days the officially authorised edition of the papers and proceedings of the Sixteenth International Medical Congress of Budapest. It will contain all the important communications presented to the Congress, the photographs and biographical notices of nearly all the members, presidents of sections, and other leading personages. This voluminous work, which is to be printed in several languages, will be sold at about 30s., and is obtainable exclusively at the Redaction of the Album of the Sixteenth International Medical Congress, Budapest, VI., Liszt Ferencz-ter, 4.

\*\*\*

"THE Sleeping Sickness Bureau," Royal Society, Burlington House, London, is about to publish in bibliographical form a work on "Trypanosomiasis," embracing original papers published prior to April, 1909, and references to works and papers on tsetse-flies, especially *Glossina palpalis*, *rob.-desv.*, compiled by Major C. A. Thimm. It will contain an almost complete list of references to the published works on sleeping sickness and the trypanosomiasis of man and animals from 1803 to March 31st, 1909, including also references to recent papers on the tsetse-flies. The price at which the book will be published (4s. net) is only sufficient to cover part of the expense of printing. Intending subscribers are requested to communicate with Arthur G. Bagshawe, Director of the Bureau.

\*\*\*

"OPHTHALMOLOGY," the quarterly review of ophthalmic science, the October number of which is before us, is an admirable publication, and although only still of comparatively recent origin, has attained to a firm position, through its excellence, among its competitors. The ophthalmic surgeon will find in its pages original articles of sound, practical interest, and abstracts of all the best work in his speciality, carefully and concisely written. Among the articles in the October number are "The Requirements and the Regulation of Signalling by Colour," "The Expression of Cataract in its Capsule" by the Editor, and "Unusual Complications in Cataract Extraction."

## MEDICAL NEWS IN BRIEF.

### New Medical Guild.

SIR JOHN TWEEDY, F.R.C.S., presided at a meeting held for the purpose of inaugurating a British Medical Benevolent Fund Guild, having for its object the assistance of distressed members of the medical profession, their wives, widows, and families. The inauguration

of such a Fund as was now proposed was, Sir John Tweedy remarked, a sad necessity, inasmuch as the medical man was often quite unable to make provision for his family, and without the benevolent fund, with which the guild to be formed would co-operate, his family would have nothing but the direst poverty before them. The assistance of ladies was urgently required to help the women and children of those who did more for the community at large than any other class.

Lady Tweedy described the objects of the Guild, and quoted a number of pathetic instances in which help had to be given by those ladies who had informally associated themselves with the work of the Fund.

Dr. West formally moved the establishment of the Guild. Lady Church seconded the motion, which was carried unanimously.

As a result of a motion proposed by Mrs. Scharlieb, and seconded by Mrs. Butlin, it was decided to draw up the rules of the Guild, and to appoint officers. We understand that members will be admitted on payment of a half-guinea subscription, and associates who will undertake the work of active co-operation, at 2s. 6d. Lady Broadbent was appointed President of the Guild, Lady Tweedy Chairwoman of the Council, Dr. Mary Thorne hon. treasurer, and Mr. Knox hon. auditor.

### Imperial Malaria Conference.

A CABLE from Simla states that the Imperial Malaria Conference has concluded its sittings and the conclusions and recommendations have been drawn up under six main heads. 1. The appointment by the Government of India of a Scientific Investigation Committee to be linked up with special organisations for dealing with malaria in each province, the investigations to be specially directed to the distribution of malaria in India, the epidemiology and endemology of the disease, and the actions of quinine and other remedies for malaria. 2. The checking by professional agency of the existing vital statistics to determine the exact causes of death. 3. Minor drainage operations, which are recommended when they are certain to be effective; the restriction of wet cultivation near towns, the introduction of fish into tanks and other collections of water, and the oiling of small collections of water, which cannot be filled up. 4. Detailed recommendations regarding the use of quinine, with reference to which the Conference advises that the drug be sold in quantities sufficient for the treatment of a case, as well as in piece packets, by all possible agencies, special efforts being made to induce private members to engage in its distribution, a liberal commission being allowed. 5. Education. On the suggestion of the President of the Conference, Sir Herbert Risley, it is recommended that committees of officials and non-officials, directed by the elected members of the new councils, be formed to spread among the people knowledge regarding malaria and the measures which it is possible to take against it. It is also recommended that the subject be taught in the schools. 6. Local governments should be invited to make an annual assignment of funds for malaria investigation and prevention.

### Remuneration of Medical Men Summoned on the Advice of Midwives.

In reference to the recommendations of the Departmental Committee appointed by the Lord President of the Privy Council to consider the working of the Midwives Act, 1902, which are as follows:—

"A secure expectation of payment should be given to a medical practitioner summoned on the advice of a midwife in a case of emergency. The Poor-law authority should be responsible for the payment, and should be empowered to charge the fee paid as 'relief on loan' to the patient;

"The scale of fees should be fixed by order of the Local Government Board on a systematic basis, having due regard to local conditions. In emergency cases, the system of a uniform fee, which should cover any ordinary after-attendance, is recommended for adoption, with the addition, perhaps, in scattered rural areas, of some allowance for mileage;

"The medical practitioner, in applying to the public authority, should be required to state that he has been unable to obtain payment of his fee from the patient or her representatives.

"A list of practitioners willing to respond to a midwives call should be prepared and circulated in every area";

The Midwives' Committee of the London and Counties Medical Protection Society recommends, and the Council of the Society has approved the recommendation:—"That, having regard to the proposed payment by Boards of Guardians of doctors called in to assist midwives, the London and Counties Medical Protection Society recommends the medical men in each Union to meet and confer on the subject, and to agree as to what fee, or fees, they will accept, and then combine to insist on such fee or fees being paid (or guaranteed) by the Guardians, and paid on the statement of the medical man that he is unable to obtain payment of his fee from the patient or her representatives."

#### Society for the Relief of Widows and Orphans of Medical Men.

A QUARTERLY Court of the directors of this Society was held on Wednesday last, Dr. Blandford, President, in the chair. Since the last Court, one of the vice-presidents of the Society, Sir Thomas Smith, Bart., has died, and a vote of condolence was passed from the chair. Sir Thomas Smith was elected a member in 1870, and had held the offices of director and vice-president. He had always taken the keenest interest in the welfare of the Society, and was a regular attendant at the quarterly Courts. One of the annuitants of the charity, a widow, had also died since the last Court. She came on the funds in 1907, and received in grants the sum of £145. The sum of £518 was voted to be distributed among the annuitants as a gift at Christmas, each widow to receive £10, each orphan £3, and the orphans in receipt of grants from the Copeland Fund £5 each. Membership is open to any registered practitioner who at the time of his election is resident within a 20-mile radius of Charing Cross. The subscription is 2 guineas per annum, or a member may become a life member by paying one sum, the amount of which is fixed by the by-laws of the Society. Relief is only granted to the widows or orphans of deceased members, and since the last Court six letters had been received from widows of medical men asking for relief, but this had to be refused, as their husbands had not been members of the Society. Application forms for membership and full particulars may be obtained from the Secretary, at 11 Chandos Street, Cavendish Square. The next election will be on January 12th, 1910. The invested funds of the Society now amount to £100,500.

#### Royal College of Physicians of London.

THE Royal College of Physicians announce the award of the Weber-Parkes prize and silver medal to Professor W. Camac Wilkinson, lecturer on medicine at the University of Sydney, for the best essay upon the prevention, pathology, or treatment of tuberculosis, especially in reference to pulmonary consumption in man; and also the award of a similar medal to Dr. Arthur Conyers Inman, of the Brompton Consumption Hospital, the essayist next in order of merit. The prize, which is of the value of 150 guineas, together with the medals, was founded in 1895 by Sir Hermann Weber, in memory of Dr. E. Alexander Parkes, and is awarded every third year.

#### Poisons and Pharmacy Act.

MR. SNOWDEN asked the Secretary of State if he was aware that town councils were issuing, in large numbers, licences to sell poisons under Section 2 of the Poisons and Pharmacy Act, 1908, in places where abundant facilities are provided by the shops of qualified chemists; and, in view of the statement made in this House by the Under-Secretary when the Poisons and Pharmacy Bill was under discussion, that licences would only be granted under Section 2 where reasonable facilities did not exist, would he take steps to stop the granting of such licences in violation of

that understanding and to cancel such licences as have been issued in contravention of it.

Mr. Gladstone, in reply, said: I am afraid I cannot add anything to the answers which I gave to questions by the hon. member on this subject on June 10th and 24th last. I have no power to control the action of the town councils, and I have already called the attention of the Privy Council Office to the allegations made.

#### British Medical Association.

THE *British Medical Journal* states that the Association has held its annual meeting in London on three occasions. The first was in 1862, when Dr. George Burrows was President; the second in 1873, when Sir William Ferguson was President; the third in 1895, when Sir J. Russell Reynolds was President. Mr. Butlin, who has already served the Association in many capacities, in particular as treasurer for six years, will be a worthy successor of these distinguished men. An announcement has already been made that it is anticipated that invitations will be given to the Association to hold the annual meeting in Birmingham in 1911, and in Liverpool in 1912.

#### Depopulation.

THE French *Journal Officiel* publishes statistics of the movement of population in France for the first half of the present year as compared with the same period last year. The chief figures are as follows:—

	1909.	1908.
Marriages ... ..	156,294	162,495
Divorces ... ..	6,148	5,605
Births ... ..	398,710	411,402
Deaths ... ..	426,913	401,894

Thus, there is a diminution of births of 12,692, and an increase of deaths of 25,019. The excess of deaths over births is 28,203, and if this proportion is maintained in the latter half of the present year the result will be even worse than in the year 1907—the sixth year since the Franco-German War in which the population of France has shown an actual diminution.

Baron d'Estournelles de Constant contributed to the *Matin* recently an interesting article on the subject. He is not a believer in prizes for large families, but he points out that the present fiscal legislation of France imposes, as it were, prizes for small ones. "It favours celibacy, childless homes, and the exploitation of woman. Childhood in France is not honoured as it is in other countries. We are disdainful toward our children; however few they may be, they seem to occupy too much room in the house. We send them out to nurse, and get rid of them until they have to go to barracks or get married. A father of a family is ridiculed. The family is taxed as a luxury, the unmarried man being positively let off lightly, as though he were a more useful servant of his country. The mother of a family cannot find employment; dogs and children are only admitted on sufferance into houses owned by respectable landlords."

#### The University of Liverpool.

At a meeting of the Faculty of Medicine held on 22nd October, the Dean announced the entries for the Winter Session as follows:—

Medical School.—New entries for Degree Courses, 23; new entries for Diploma Courses, 8, total, 31; total number of undergraduates registered, 132; new entries for the Diploma of Tropical Medicine, 19; new entries for the Diploma of Public Health, 13.

Dental School.—New entries for Degrees and Diplomas, 14; total number of dental students registered, 42.

#### Royal Sanitary Institute.

THE following have been admitted members of this Institution:—

S. N. Banerjee, I.M.S., Hospital, Salkea, Hourah, Bengal, India; John H. Garrett, M.D., D.P.H. (M.O.H.), Municipal Offices, Cheltenham; David D. Gold, M.D., C.M., D.P.H. (M.O.H.), Shirehall, Hereford; Thomas E. Holmes, M.A., M.D., B.C. Cantab., D.P.H.Lond., Nottingham; John Howard-

Jones, M.D., D.Sc., C.M. (M.O.H.), Health Dept., Newport, Mon.; Thomas H. Lovegrove, M.R.C.S., Perth, Western Australia; Harry Mason, M.B., Ch.B., D.P.H., Harrogate; Andrew Smith, M.D., L.R.C.S. Eng. (M.O.H.), Whickham, Durham; Donald Steel, M.B., Ch.B., Perth, Western Australia; John I. Taylor, L.R.C.P., M.R.C.S., Willesden Green, N.W.; John Utting, M.R.C.S., L.R.C.P., J.P., St. Anne's Hill, Liverpool; David E. Williams, L.R.C.S.I., L.R.C.P.I., Port Health Officer, Fremantle, W. Australia.

### PASS LISTS

#### Royal College of Physicians of London.

THE following candidates having passed the necessary examination of the Conjoint Examining Board, Licences to Practice were conferred on Thursday last:

Edward M. Adam, L.M.S., Stanley D. Adam, William A. Alexander, B.A.Cantab., Tom C. R. Archer, Enoch T. Atkinson, M.D., C.M.Toronto, Harry L. Attwater, B.A.Cantab., Cuthbert C. H. Binns, B.A.Cantab., Cuthbert J. Blaikie, B.A.Cantab., Norman A. Boswell, Thomas S. Bradburn, Rex C. Brewster, Lancelot Bromley, B.A.Cantab., Edward M. Browne, Sidney H. Browning, Edward S. Calthrop, Guy O. Chambers, Algernon E. P. Cheesman, William N. Child, M.A.Cantab., Eric A. Collins, William V. Corbett, Aston R. Dale, Max E. Dellschaft, B.A.Cantab., Anthony Dias, Daniel C. Druitt, Ernest A. Dyson, B.A.Cantab., Isaac M. Edis, Arthur O. English, Anthony Feiling, B.A.Cantab., Samuel C. R. Flaxman, Patrick C. Fowell, B.A.Oxon., Reginald C. H. Francis, Arthur J. Friedlander, Cyril G. Galpin, Harman J. H. Graves, Henry Gray, Frank M. Harvey, Guy F. Haycraft, Geoffrey R. Heard, Wilfrid L. Hibbert, Reginald H. P. Hick, Thomas T. Higgins, M.B., Ch.B.Vict., Richard Howey, M.B.Toronto, Gilbert P. Humphry, Harold E. Jeffreys, M.B., Ch.B. New Zea., Chhaganlal H. Kantawala, Bombay Univ., Rustom D. Kapadia, L.M. and S. Bombay Univ., Edward M. Lauderdale, B.A.Cantab., Ernest C. Lindsay, Arthur G. H. Lovell, Donald McCully, Daniel R. McDonald, M.D., C.M., Niel McDonald, M.B., Ch.B.Vict., Alexander E. McKenzie, Paulin J. Martin, Philip S. Martin, Leslie Meakin, B.A.Cantab., John M. Mehaffey, John Mellor, Robert M. Miller, B.A.Cantab., Claude H. Mills, Thomas A. Milroy, Douglas A. Mitchell, Hugh G. Monteith, B.A.Cantab., Alfred F. Morcom, B.A.Cantab., Frank C. Morgan, John F. H. Morgan, Willem Mulder, M.D.Utrecht, Clive Newcomb, B.A.Oxon., Bertram C. N. O'Reilly, John G. Owen, William H. Peacock, M.B., B.S.Durh., Guy H. Peall, Richard B. Philipps, Edward H. Rainey, Edward L. N. Rhodes, B.A.Cantab., Robert S. Richardson, M.B.Toronto, John L. Ritchie, Charles D. Roberts, Cecil J. Rogerson, Christopher Rolleston, Charles E. F. Salt, Edward A. Seymour, Clement E. Shattock, James S. Simpson, M.D., C.M.McGill, Frank L. Smith, Henry S. C. Starkey, B.A.Cantab., Lawrence Storey, M.B., Ch.B.Glas., Arnold W. Stott, B.A.Cantab., Charles H. S. Taylor, B.A.Cantab., Henry H. S. Templeton, Richard M. R. Thursfield, B.A.Cantab., Francis C. Tibbs, Karl J. Titlestad, William W. C. Topley, B.A.Cantab., Charles E. Walker, M.Sc. Liv., Sidney H. Ward, Arthur A. M. Werapernall, L.M. and S.Ceylon, Charles F. Willes, Gwilym A. Williams, B.A., Thomas J. Williams, Charles S. Wink, Kenneth Wolferstan, Duncan Wood, James C. Woods.

#### Trinity College, Dublin.

THE following candidates have passed the Preliminary Scientific Examination, Michaelmas Term, 1909:—

Physics and Chemistry.—Theodore Allen, Robert A. Flood, Reginald H. Jones, William Foot, Joseph Harvey, John W. C. Stubbs, John A. MacMahon, Rupert C. Lowe, Henry C. D. Miller, Hawtrey W. Browne, Kathleen D. Wallace, Eleanor Taylor.

Botany and Zoology.—Amos G. Varian, John T. McCullagh, George S. McConkey, Joseph Harvey, Ernest Bantry White, Hilda M. B. Marsh, Frederick R. Sayers, Michael J. Ryan, Bertram Sheridan, Frederick A. Sparling.

Intermediate Medical Examination—Part I.—William O. W. Ball, William P. Croker, Walter Crane, Jane F. Colquhoun, Maurice Horan, Marjory Chapman, Charles F. Judd, James N. G. Nolan, Francis V. Agnew.

Previous Dental Examination.—Anatomy and Institutes of Medicine.—Henry Kirk.

The following candidates have passed in the Final Medical Examination, Michaelmas Term, 1909:—

Part I.—Harry H. James, passed on high marks; Charles O'Brien, Hugh R. M. Ferguson, Hans Fleming, Gervase W. Scroope, Cecil Grene, James H. Crane, Victor G. Best, William M. Johnstone, Charles D. Hanan.

Jurisprudence and Pathology.—John W. Tomb.

Pathology (supplementalist).—John G. Ronaldson.

Intermediate Medical Examination.—Part II.—

Jacobus M. S. Gericke, passed on high marks; Antonie C. Redelinghuys, Oswald C. S. Tandy, Robert G. Ball, William A. Taylor, Henry P. Harpur, Maurice Horan, James C. Kelly, Humphrey L. Blackley, Herbert G. Holdbrook, Leonard Shiel, Edward H. P. Murphy, Charles F. Judd.

#### Conjoint Examinations in Ireland.

THE following candidates have passed the Preliminary Examination of the Royal College of Physicians and the Royal College of Surgeons:—

S. H. Bannerman, W. J. Broderick, A. F. Carbury, J. Daly, T. Flynn, J. Fox-Russell, G. P. Healy, J. J. Hutton, M. J. B. Kennedy, Miss M. Lees, P. S. McCabe, A. McCawley, J. A. Musgrave, J. O'Carroll, E. O'Keeffe, F. J. Power, A. Porter, G. M. C. Powell, F. J. Robinson, N. A. K. Sparrow, T. H. Sarsfield, W. J. Sweeney, H. J. Swan, P. W. Walsh, S. Weinstock, L. E. Wigoder.

The following have passed the First Professional Examination:—

J. P. Brennan, B. J. Cusack, J. J. L. Cox, H. A. S. Deane, E. G. Foley, A. B. Foot, R. F. J. Griffith, R. Green, J. F. Lyons, D. McEntire, R. J. May, C. J. O'Carroll, H. V. O'Donoghue, P. Rowan, T. F. Ryan, G. N. Smyth, R. Tivy.

The following have passed the Second Professional Examination:—

M. J. Ahern, A. J. Best, C. M. G. Campbell, T. J. Kelly, D. Murphy, G. Sheehan, G. A. Shiel, W. Waugh.

THE following candidates have passed the third Professional Examination of the Royal College of Physicians and the Royal College of Surgeons, October, 1909:—F. M. J. Byrne, T. Farrell, M. Golding, E. Holden, F. Hannigan, F. P. Kennedy, P. B. Kelly, N. Keating, A. G. MacIlwaine, W. G. Maguire, P. H. McDonough, C. Molan, B. O'Donnell, T. P. O'Reilly, T. F. O'Donnell, K. O'Sullivan, J. B. Power, L. C. Rorke, P. Ross-Todd, J. V. Ryan, L. W. Roberts, J. C. Scanlan.

#### Royal Colleges of Physicians and Surgeons of Edinburgh and Faculty of Physicians and Surgeons of Glasgow.

THE following candidates having passed the Final Examination, were admitted L.R.C.P.E., L.R.C.S.E., and L.F.P. and S.G.:—

Frederick B. Carvalho, Raghunath A. Barve, Richard D. Neagle, Harold H. Field-Martell, Martin Remers, Anthony F. Henriques, Kuppusami T. Nath, Reginald A. Hosegood, William R. MacKenzie, Sydney Sharples, Beatrice Coxon, George B. Moon, Rupert V. Dias, Dinshaw B. Gazdar, Maud D. Fére, Howard V. A. Gatchell, and Fritz C. Eberhardt; and 3 passed in Medicine and Therapeutics, 7 in Surgery and Surgical Anatomy, 9 in Midwifery, and 21 in Medical Jurisprudence.

WE understand that a movement is on foot to commemorate in fitting fashion the connection of the late Professor Daniel John Cunningham with Trinity College, Dublin. A meeting of those interested will be held next Wednesday, November 10th, in the Medical School, Trinity College, the Provost in the chair.

## SUMMARY OF RECENT MEDICAL LITERATURE, ENGLISH AND FOREIGN.

*Specially compiled for THE MEDICAL PRESS AND CIRCULAR.*

[SPECIALLY REPORTED FOR THIS JOURNAL.]

**A Case of Struma Ovarii.**—Frank (*Amer. Journ. of Obst., LX., 3*). The patient, æt. 22, had been married 8 months, and never been pregnant. The sole complaints were backache and leucorrhœa. A curettage was first performed, and then the abdomen opened, and a tumour the size of a peach, involving the right ovary, easily removed. The tumour was ovarian in shape, irregularly bossed, and enclosed in a thickened tunica albuginea. On cross-section the growth was seen to be composed of irregular angular cysts, greatly varying in size, filled with colloid material. At one pole there was a hard, bony shell, containing a molar tooth. Microscopical examination of the growth showed the dense hæmorrhagic area to be a corpus luteum, with hæmorrhagic infiltration. The bone was normal. The rest of the tumour was identical with colloid goitre. In some parts the acini were of normal size, but closely crowded together, and containing little colloid. In a few spots there was slight tendency to atypical adenomatous growth. The greater part of the growth was formed by irregular cysts filled by colloid material, and lined with a single layer of low cubical epithelium. F.

**A Case of Decidual Expulsion Occurring at Each Menstrual Period.**—Frank and Scroggs (*Amer. Journ. of Obst., LX., 3*).—A woman, æt. 27, had given birth to a child when 24. Since then she had at her menstrual periods severe pains like labour pains, and was only relieved after the expulsion of a cast-like membrane, before which a bloody discharge began. On three occasions her physician attended her, and saw a complete membranous cast of the uterine cavity, and on two other occasions, while under observation, similar casts were expelled. The surface of the cast is finely granular, and, on opening it, both tubal cornua can be seen, and the internal surface shows granular elevations. The membrane is more than 1 cm. thick. The histologic examination shows a marked decidual formation, with differentiation both in the spongy and compact layers; the decidual cells are generally round and sharply defined with deeply staining nuclei. There is always a diffuse infiltration of round cells, and some very compact islands; many of the blood-vessels and sinuses show thrombosis. The diagnosis of an acute inflammatory condition is made on account of the islands of lymphocytes. This membrane is not such as is found in cases of dysmenorrhœa membranacea, but a true decidua, although no part of an ovum was found. F.

**A Case of Syphilis without a Primary Chancre.**—Magian (*Brit. Med. Journ., September 11th, 1909*) reports that two years ago a gentleman informed him that he was afraid he had contracted a venereal disorder three days previously. Sexual congress was brief, and patient had washed himself immediately afterwards. He became suspicious on noticing a rash on his partner's arm. He had only once had sexual intercourse two and a-half years previously, with no untoward result. He was to be married the following day. As, against advice, he had intercourse with his wife, he became very nervous, and insisted on being daily examined by the writer for any signs of venereal disease. As the patient was afraid of extra-genital chancres, he was completely examined twice a week. At the end of eight weeks the examination was made once a week. The writer is convinced that nothing had been overlooked. There was no suspicion of chancre or sore of any kind on any part of the patient's body. The urethra, rectum, and mouth were equally free from disease. Yet at the beginning of the eleventh week he appeared with the body covered with a roseolar rash. Sore throat, loss of hair, iritis, periostitis of the tibia, gumma of the testicle followed. After 12

weeks his wife aborted of a three months' fœtus. Soon after she broke out into a pustular eruption, suspected her husband, and left him. Subsequently the husband went back to his former mistress, and the writer saw him again suffering from a Hunterian chancre on his glans penis, where he was re-infected in a period under two years with the same disease. S.

**The Common Cold.**—Campbell (*Practitioner, October, 1909*) discusses this often trivial yet always annoying complaint. The condition may be due to purely nervous causes, but is most frequently due to some specific bacterial infection. The common organisms which cause a "cold" are Friedlander's bacillus, the bacillus septicus, the bacillus of influenza, and the micrococcus catarrhalis. These organisms give rise in the susceptible to specific febrile disorders, but, unlike the exanthemata, these disorders do not confer immunity for more than a very limited period, sometimes for not more than a few weeks. As regards treatment, something may be done by the ordinary orthodox methods to relieve the symptoms, but, in spite of the treatment, the disease usually runs its course. By prophylactic treatment much may be done. Besides a careful observance of the ordinary rules of hygiene, care should be taken to see that the upper air passages, especially those of the nose, are in a healthy state. Much may also be done by regulating the diet. Both over-eating and the eating of wrong kinds of food are said to engender the catarrhal diathesis. The supply of starch and sugar in the diet should be especially limited. Undoubtedly the most scientific and satisfactory way of treating this class of disorders is by means of vaccines, by which we may not only cut short an acute cold, but also confer a considerable immunity against future attacks. Except in cases of infection by the bacillus septicus there are few cases of common cold that can be treated by the ordinary stock vaccine, and it will generally be necessary to have a vaccine specially prepared from the organism by which the patient is infected. One should always begin with a small dose, about 120-million organisms, and increase in subsequent injections according to the progress of the patient. In acute cases one should avoid any reaction, but in chronic cases a slight reaction is sometimes beneficial. K.

### Medical Sickness and Accident Society.

At the usual monthly meeting of the Executive Committee of this Society, Dr. de Havilland-Hall was in the chair.

The accounts presented show, as usual, a great falling off in the sickness claims, both in number and duration during the summer months, as compared with the experience of the winter. In a Society formed for the most part of medical men in general practice, and therefore liable to exposure to bad weather, it is clear that such a result as this must be looked for.

The financial results of the year's working have so far been very satisfactory, and as in every previous year of the Society's history, a substantial addition has been made to the invested reserves.

### Cholera.

CHOLERA appears to be steadily fighting all the precautions which are being taken to keep it out of Western Europe. Cases of this disease are to be found in Eastern Prussia, and it is said that several deaths from cholera have occurred near Antwerp, the infection having been brought in these latter cases by Dutch-boatmen.

## NOTICES TO CORRESPONDENTS, &c.

**FOR CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

### SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs 15.12. Messrs. Dawson and Sons are our special agents for Canada.

### ADVERTISEMENTS.

**FOR ONE INSERTION**—Whole Page, £3; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

**QUACKERY LAW.**—When Mr. Darker's article was in type it was found that the function of the General Medical Council was not put in the Council's powers are chiefly used internally against the profession. The Medical Defence Union taking on the Council's function as to outsiders.

**SENIOR STUDENT.**—There can be no better preparation for general practice than a twelve months' experience as house surgeon in a general hospital; and a man with the personal qualities of a gentleman and with capital, can usually find a partnership in a good general practice if, besides being really well qualified, he possesses the confidence which experience brings.

**A CHICAGO SUBSCRIBER.**—The efficiency of British laws (good as most of them undoubtedly are) depends upon parochial authorities; and, whilst the supervision of foods and drugs is effectual in some localities, the laws are in many places either altogether ignored or very laxly administered.

### LIFE AND DEATH.

A CORRESPONDENT sends the following:—

"The world is like a railway station,  
Where we all arrive and leave.  
When we come congratulation,  
When we go how few to grieve!  
Yet, we all must die alone,  
Destiny of each unknown!  
Life is but transition state,  
Everyone must bow to fate."

A. D.

**A CANDIDATE.**—The Indian Medical Service affords to superior men opportunities for advancement in some directions superior to those in the R.A.M.C.

**MATER.**—It is easy to find in most neighbourhoods a family doctor upon whom reliance may be placed; and it is best to ask his advice always before choosing a specialist when one is really required.

**WINTER CLIMATE.**—Algiers is easily reached *via* Marseilles, and there are English physicians resident there.

## Meetings of the Societies, Lectures, &c.

### WEDNESDAY, 3RD NOVEMBER.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.).—4 p.m.: Mr. A. P. Gould: Clinique (Surgical). 5.15 p.m.: Lecture: Dr. A. E. Giles: The Menopause, Natural and Artificial.

**NORTH-EAST LONDON POST-GRADUATE COLLEGE** (Prince of Wales's General Hospital, Tottenham, N.).—Clinics: 2.30 p.m.: Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 p.m.: X-Rays (Dr. H. Pirie).

### THURSDAY, 4TH NOVEMBER.

**NORTH-EAST LONDON CLINICAL SOCIETY** (Prince of Wales's Hospital, Tottenham, N.).—4.15: Clinical Meeting.

**ROENTGEN SOCIETY** (20 Hanover Square, W.).—8.15 p.m.: Ordinary General Meeting.

**ROYAL COLLEGE OF PHYSICIANS OF LONDON** (Pall Mall East).—5 p.m.: Sir T. Clifford Allbutt, K.C.B.: Greek Medicine in Rome. (Fitz-Patrick Lecture.)

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.).—4 p.m.: Sir Jonathan Huthinson: Clinique (Surgical). 5.15 p.m.: Lecture: Dr. L. Guthrie: Some Nervous Affections in Children.

**NORTH-EAST LONDON POST-GRADUATE COLLEGE** (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynaecological Operations (Dr. A. E. Giles). Clinics: Medical Out-patient (Dr. A. J. Whiting); Surgical Out-patient (Mr. Carson). 3 p.m.: Medical In-patient (Dr. G. P. Chappell).

**ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN** (Leicester Square, W.C.).—6 p.m.: Chesterfield Lecture: Syphilis: History and Primary Invasion (Constitutional, Local). Eruptions, Erythematous: I., Macular; and II., Maculo-Papular.

### FRIDAY, 5TH NOVEMBER.

**ROYAL SOCIETY OF MEDICINE (LARYNGOLOGICAL SECTION)** (20 Hanover Square, W.).—5 p.m.: Cases and Specimens will be exhibited by the following:—Mr. Seccombe Hett, Dr. Dan

McKensie, Dr. StClair Thomson, Dr. Jobson Horne, Mr. Stuart-Low, Dr. Dundas Grant, Dr. Dundas Grant and Dr. Dan McKensie, Dr. Irwin Moore, Dr. Clayton Fox, Mr. E. B. Waggett, Dr. Scanes Spicer.

**ROYAL SOCIETY OF MEDICINE (SECTION OF ANÆSTHETICS)** (20 Hanover Square, W.).—8.30 p.m.: Paper: Dr. Vivian Orr: Heart Massage in Chloroform Syncope. Short Communication: Dr. R. H. Hodgson: An Apparatus for the Administration of Ether by the Open Method.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.).—4 p.m.: Dr. J. Horne: Clinique (Ear, Nose, and Throat).

**NORTH-EAST LONDON POST-GRADUATE COLLEGE** (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinio: Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Operations (Mr. W. Edmunds). Clinics: Medical Out-patient (Dr. A. G. Auld); Eye (Mr. R. P. Brooks); Skin (Dr. G. N. Meachen). 3 p.m.: Medical In-patient (Dr. R. M. Lealie).

**CENTRAL LONDON THROAT AND EAR HOSPITAL** (Gray's Inn Road, W.C.).—3.45 p.m.: Lecture: Mr. Stuart-Low: Accessory Sinuses.

### TUESDAY, 9TH NOVEMBER.

**CENTRAL LONDON THROAT AND EAR HOSPITAL** (Gray's Inn Road, W.C.).—3.45: Larynx: Dr. A. Wylie.

## Appointments.

**BENNER, ALBERT E., M.B., Ch.B. Edin.**, Senior House Surgeon to the Blackburn and East Lancashire Infirmary.

**CLAYTON, F., M.D., M.R.C.S., L.R.C.P. Lond.**, House Physician to University College Hospital.

**DAVIES, T. B., M.B., B.S., M.R.C.S., L.R.C.P. Lond.**, House Physician to University College Hospital.

**EMANUEL, J. G., M.D., B.S., B.Sc. Lond.**, M.R.C.P. Lond., Honorary Physician to Queen's Hospital, Birmingham.

**FRASER, FORBES, F.R.C.S. Eng.**, Honorary Surgeon to the Royal United Hospital, Bath.

**MAURICE, W. B., M.R.C.S., L.R.C.P. Lond.**, Certifying Surgeon under the Factory and Workshop Act for the Marlborough District of the county of Wilts.

**NIXON, SIR CHRISTOPHER, Bart., M.D. R.U.I., F.R.C.P. Irel.**, Professor of Medicine in the University College, Dublin.

**STYKS, HAROLD W., M.B., B.S.**, Senior House Surgeon to the Ingham Infirmary, South Shields.

**WALKER, A. S., M.B., Ch.B. Edin.**, Medical Officer to the Leith School Board.

## Vacancies.

**Nottingham General Dispensary.**—Assistant Resident Surgeon. Salary £160 per annum, with apartments, attendance, light, and fuel. Applications to C. Cheesman, Secretary, 12 Low Pavement, Nottingham.

**Kent County Asylum, Chartham.**—Third Assistant Medical Officer. Salary £145 per annum, with board, quarters, attendance, and washing. Applications to Medical Superintendent, Chartham, near Canterbury.

**Staffordshire County Asylum, Cheddleton, Leek.**—Senior Assistant Medical Officer. Salary £250 per annum, with board, apartments, and washing. Applications to the Medical Superintendent.

**Staffordshire County Asylum, Cheddleton, Leek.**—Junior Assistant Medical Officer. Salary £200 per annum, with board, apartments, and washing. Applications to the Medical Superintendent.

**The Hospital for Sick Children, Great Ormond Street, London, W.C.**—Fourth Anæsthetist. Honorarium of £15 15s. voted on the expiration of each year of office. The sum of £6 6s. is also voted to provide a substitute during three weeks in the summer. Applications to the Secretary.

## Births.

**COUTTS.**—On Oct. 27th, at 29 Surrey Street, Norwich, the wife of D. K. Coutts, F.R.C.S., of a daughter.

**LUMSDEN.**—On Oct. 24th, at 4 Fitzwilliam Place, Dublin, the wife of J. Lumsden, M.D., of twin daughters.

**TURNER.**—On Oct. 25th, at Park House, Church End, Willenden, London, N.W., the wife of W. E. Turner, M.R.C.S., L.R.C.P., of a son.

## Marriages.

**HAYNE-MORISON.**—On Oct. 30th, at Holy Trinity, Paddington, Louis Brightwell Hayne, M.D., of Harrogate, second son of Henry Hayne, Tunbridge Wells, to Margaret Lillias Morison, daughter of the late Murdoch Shaw Morison and of Mrs. Morison, of 17 Orsett Terrace, Hyde Park, London.

**HIND-BIGG-WITHER.**—On Oct. 26th, at St. Mary's Church, Shalford, near Guildford, Henry Hind, F.R.C.S., to Helen, only daughter of Colonel and Mrs. A. G. Bigg-Wither, of Tithams, Godalming.

## Deaths.

**EMBLETON.**—On Oct. 27th, at 2 Whitehill Hill, Hampstead, Eva O. J., wife of the late Dennis Embleton, M.D., M.R.C.S., L.R.C.P., of Bournemouth.

Vol. CXXXIX.

WEDNESDAY, NOVEMBER 10, 1909.

No. 19.

## NOTES AND COMMENTS.

**An Underground Cure for Asthma.** YEARS ago in London one of the popular cures for asthma took the form of travelling in the underground railway. It was conjectured in some medical quarters, we remember, that possibly the sulphurous fumes with which the tunnels were charged might really have had some beneficial effect on the disease. One enterprising railway porter, so it was recorded long ago in the columns of this very journal, went so far as to make pills out of the soot scraped from the walls of the underground railway near King's Cross, where the air was always thick with sulphur. Report went that he did a thriving trade with these pills. Now that the railway in question is electrified the air is no longer sulphurous and the walls no longer begrimed with soot. Its fame for the cure of asthma has departed, but, wonderful to relate, it has found refuge in a neighbouring tunnel, namely, that of the Central London "tube" railway. It was solemnly announced last week in the pages of a London daily newspaper that the mother of a well-known duchess was in the habit of travelling on the line in order to get relief for her asthma. Although it is within the bounds of possibility that the locality may provide the remedy in some rare individual instances, it is impossible to believe that a new cure of any general value has been discovered therein. It is quite refreshing to find so simple and harmless a cure advertised in a London newspaper.

**A New "Cure" for Asthma.** THE recent exposures of quack remedies, show that nothing is too worthless or inert to be sold as a "cure," and no method of treatment too palpably ridiculous to bring in a harvest to those who exploit it. Thus, one of the most widely-advertised quack nostrums of modern times, advertised to cure several score maladies, has been shown to consist of sugar pellets, pure and simple. Could the force of cynical knavery further go? Curiously enough, wealthy and well-educated people are just as easily gulled as the poor and the ignorant, although it may be assumed in smaller numbers. One of the favourite diseases of the patent-medicine men is asthma, a symptomatic trouble that is apt to bring its own relief, and for which there are a host of orthodox remedies. As every medical man knows, asthma often follows a mysterious course. A patient may suffer in the country and be free in a slum; he may be a martyr in one quarter of the town and become immune in another; or he may find relief by merely changing house to the opposite side of the street. All these

vagaries furnish a fine vantage ground, not only for the wily quack, but for the numberless persons who are always on the look-out for this, that, or the other royal road to the cure of their own or of other folks' diseases.

THE death is reported of Dr. **A Mafeking Medical Hero.** William Andrew Hayes, an Irishman, who first came into prominence as the principal medical officer during the famous siege of Mafeking. He had a large and varied experience during his comparatively short span of 48 years, which came fitly to an end in the town of the historic siege. The story, as recalled in the London papers, reminds us that in August, 1899, Dr. Hayes hurried back to the Cape from England, whither he had come on business. In his own mind he was convinced that war must break out, indeed, he ordered a large supply of dressings and other medical stores to Mafeking, which he reached late in September. Unluckily, there was no time to execute his orders, and he shortly afterwards found himself in responsible medical charge of a besieged town, with only two qualified medical men to help him, namely, Major L. E. Anderson and Mr. T. W. Hayes, and an absolute shortage of all ordinary hospital stores. How the situation was met every Englishman knows. Not the least wonderful of Dr. Hayes' feats was the organisation of a nursing staff from among the ladies of the town, delicately nurtured as they were and unaccustomed to the sights and sounds of army medical work at the front.

**Mafeking Nurses.** It was the present writer's fortune to be acquainted with one of these ladies, who lost her husband during the siege. On Sundays it was the custom of the Boers to cease firing, but on one occasion they were annoyed at some frivolity that had gone on in the town, and they re-opened fire. The lady's husband was shot through the body while riding on a bicycle. He was able to go home and give directions as to his affairs before going into hospital. After a few hours severe abdominal pain set in, and he died not long afterwards. Among the many instances of recovery from serious wounds was one recorded by Dr. Hayes of a Cape policeman who was shot through the liver. He was compelled, almost forcibly, to lie in bed for a week; and though in much pain, he constantly begged to be allowed to return to duty, in order that he might "wipe out the insult." At the time of his death Dr. W. A. Hayes was a medical officer of the Cape Government and a surgeon-lieutenant of the Bechuanaland Rifles. His brother, Mr. T. W. Hayes, is district surgeon at Mafeking and a surgeon in the Cape Mounted Police.

**"Doctor's Singular Letter."** FROM a provincial paper, under the above heading, we learn that on the 2nd inst., Mr. Kenrick, Coroner for East Denbighshire, held an inquest on the body of a woman who, after partaking of her tea in the afternoon, suddenly fell down and expired. Dr. Moss, of Wrexham, was called in, but the poor creature was already dead on his arrival. Dr. Moss was not summoned to the inquest however. The Coroner said he had written to Dr. Moss about the case, and had received the following reply:—"Dear Mr. Kenrick,—I was called to see Mrs. Phoebe Jones, of 84 Vernon Street, Wrexham, shortly after five o'clock. On my arrival she was dead. I cannot say what was the cause of death, but the commonest causes of sudden death are heart affections, brain lesions (especially pontine hæmorrhage), aneurysms, perforations of the abdominal viscera, poisonings. You can take your choice out of this lot. Yours sincerely, E. Moss." The jury returned a verdict to the effect that the cause of death was heart failure. Now, will any unbiassed individual say that the verdict here given was of the slightest value, and that the fees paid, or to be paid, to officials of the court were not so much money thrown away? To make the inquest of any value, the doctor ought to have been summoned in due course, and facilities should have been afforded for arriving at a scientific conclusion. This would have cost the county a fee, but without it the fees it had to pay were so much money wasted. When coroners give their valuable services "free gratis," it will then be quite time enough for them to expect doctors to be equally altruistic. The letter quoted appears to be a kind of protest against being expected to do professional work for nothing. It would be a good and proper thing for doctors to have at hand a printed form of reply suitable for such unreasonable requests.

## LEADING ARTICLES.

### A NEW MEDICAL SERVICE.

It is unnecessary to remind medical readers of the existing Services open to our profession—the Army, Navy, India, Poor-law, and so on. The doctors in the employ of our West African possessions have, however, been evolved into a Service on sound basis. Time was when the only European medical aid to be had on the West Coast of Africa was that of some half-sporting, half-exploring medico who had come out on a ship and who had made up his mind to stay a while. In Sierra Leone, the Gold Coast, and in Lagos, he became, or his place was taken long ago by the colonial surgeon, but in Southern Nigeria the extinction of the independent doctor occurred only about fifteen years ago. Now all the colonial doctors have been chosen by the Secretary of State for the Colonies, and the West African Medical Staff is the result. The difficulty that arose was that for the proper management and success of medicine on the Coast, especially in the matter of sanitation, co-ordination became absolutely necessary. For this the head at home—viz., the Secretary of State, should be able to seek authoritative advice. Early this year a Colonial Office Departmental Committee on the West African Medical Staff sat, and its Report was presented to both Houses of Parliament, by command of His Majesty, in July, 1909. This Committee

prefaced its Report by urging that it appeared from the evidence they had taken that the medical officers wished to make the Colonial Medical Service their career, and that they "have therefore based their Report upon the hypothesis that it is desirable to encourage medical officers to make the West African Service their permanent career." The essence of the Report is, that an Advisory Medical Board should sit in London to advise the Secretary of State on medical or sanitary questions which he may wish to refer to them. Such questions might comprise schemes for drainage and water supply, plans for the prevention or stamping out of epidemic disease, bacteriological research, selection of candidates, courses of study, and so on. This Board has now been formed, and it should be the means, not only of securing for the 160 medical officers of the West African Medical Staff a real opportunity, but may very well be the nucleus or germ of a very much larger body in the future. At the same time facilities are to be given for the principal medical officers of each Colony to meet on the Coast and confer "on the spot," as it is called in this country. By this means a uniform, continuous and determined effort will be made to combat all those lowly organisms which the ever present heat and moisture foster, and which, when they find man a suitable host, give expression in what is called disease.

## CURRENT TOPICS.

### The Progress of Cremation.

CREMATION is not making as much headway in the United Kingdom as its supporters maintain the movement deserves. Last year cremations in this country numbered 871 against 795 in the previous year. In Germany the number in 1908 was 4,050, as compared with 2,977 in 1907. The returns of the Manchester Crematorium state that last year there were 117 cremations, the total number of cremations since the opening of the Crematorium in 1892 has been 1,319; reduced fees were accepted in 46 cases. The interest of the general public in inspecting the Crematorium still continues to manifest, and during the year 1,130 visitors were admitted on payment of a small fee. There is little active opposition to cremation, though the feeling that it was un-Christian still had some hold. Yet the Bishop of Manchester and his two predecessors and many clergymen of all denominations believed in cremation. So far as the sanitary aspects of cremation are concerned, there can be no question that its position is unassailable, and that the wisdom of many prehistoric and ancient races in that particular has been amply vindicated by latterday science. But the action of reason against prejudice and sentiment, needless to remark, is often of the slowest.

### Reform of the Poor-Law.

WITH publication last week of the section dealing with Scotland the Report of the Royal Commission on the Poor Laws is now complete. In this Report the medical profession are interested as patriotic

citizens anxious for the welfare of the State, and as civil servants playing an important part in administration of the laws in question. No class can be in a position to recognise so well as the medical profession the need for reform of our present system; it is wasteful, it is demoralising, it is cruel. From end to end it is entirely indiscriminating. It matters not whether the tramp or wayfarer be a decent working man or an idle, vicious professional beggar, exactly the same treatment is meted out to him in the casual ward. It matters not whether the poverty-stricken applicant for help has been brought low by unavoidable and undeserved misfortune, or pauperised by drunkenness, idleness, and improvidence, exactly the same treatment is applied, whether in the form of outdoor or indoor relief. And the same confusion prevails throughout. The first step in reform must consist in a sorting out of the classes of paupers, and application of the proper treatment to each variety. The physically, morally, and mentally unfit, the different classes of temporary and permanent "unemployables" must be taken in hand, and dealt with according to the causation of their respective conditions. A great many of the problems which confront us have been solved in countries of Western Europe, and there can be no difficulty in adapting many of their methods to meet the requirements of our own people while respecting the feeling for the liberty which is supposed to dominate the British public. The question of Poor-law reform is not a party one; it must be taken in hand speedily by whatever Government is in power. The construction of effective laws will need the co-operation and the advice of the medical profession; co-operation of experts in medical Poor-law administration, and advice of experts in problems of public health bound up in the whole question of pauperism. In the end the status of the Poor-law medical officer must surely be improved; it cannot, at any rate, be easily made worse than it is at present.

#### Administration of Public Health Acts.

FROM week to week this subject is before readers of the Medical Press. Illustrations are constantly appearing of the enormous improvement in the public health, which, on the whole, has been brought about by the sanitary legislation of the last fifty years, whilst an equal number of illustrations are at the same time provided of how much more could be achieved if the authorities responsible for the sanitary condition of their districts would perform even a fair part of their duty. This lax administration inflicts hardships almost alone upon the poor, and for this reason mainly it is so often ignored by classes of the public who ought to be responsible. These facts are either forcibly stated or suggested in a letter in which the Duke of Northumberland replies to a group of tenants under notice to quit certain cottages ordered to be closed by the magistrates. The tenants had tried to get other houses, but had failed to do so, and had asked for an extension of time. The Duke points out that the blame in these cases rests entirely upon the local authorities. With some exceptions they have

gone to sleep, and have allowed houses which were old and dilapidated half a century ago to get worse and worse; they have neglected to see that dwellings more recently erected have been adequately maintained; they have failed to provide houses for ejected tenants before condemning the only habitations available. The neglect of generations cannot be remedied merely by closing houses and turning the occupants into the streets. If the Housing Bill now going through its final stages in Parliament should become law, it is possible some of these evils may be put an end to. It will, perhaps, provide means of rousing local authorities to a sense of their duty, and of putting pressure upon or coercing any that show themselves recalcitrant.

#### An Illustration from Wales.

WHILST the foregoing paragraph is being penned there comes to hand from a respected medical correspondent in the county a description of the condition of certain villages near the town of Carnarvon, as revealed in a recent report by the Medical Officer of Health, Dr. E. Le Parry Edwards. A large number of houses in these villages are seriously defective; many of them are back-to-back, and with wholly inadequate "sanitary arrangements." There are windows that do not open, and a total absence of ventilation, due to blocking up of chimneys. Over-crowding and mixing of the sexes prevail, including conditions worse than the medical officer had ever seen, "either among blacks or white men." The District Council was asked to give a peremptory order to close the worst of these; and but for the scarcity of proper dwellings in the district, the Council would have been urged to issue closing orders in a large proportion of cases. The discussion at the Rural District Council contributed some suggestive observations. It was affirmed, without contradiction, that the district was no worse than others in the county, whilst one councillor "feared that ties of friendship too often rendered it difficult for that and other public bodies to set the law in motion." In other words, the Councils are declared capable of sacrificing the welfare of the poor and helpless classes in order to serve the sordid ends of their personal friends. This is a charge which it might be thought would have been left to be brought by the enemies of the Councils; formulated and expressed by a friend without protest from the other members, no one can possibly venture to deny its truth. Local government (as we constantly insist) fails because the authorities are, as a rule, dominated by inferior men. The resulting evils (as we also so often urge) can be cured only by the development of local patriotism with consequent improvement in the personal qualities of councillors. Failing this, the only remedy lies in increasing the coercive powers of the Local Government Board, a measure which, in the presence of developing democracy, seems far outside the scope of present-day practical politics.

#### Co-Education.

CO-EDUCATION, the education of boys and girls together, has made considerable progress during

the past twenty years. During this time schools for boarders up to the age of nineteen have been established on English public school lines, and their founders now claim that there has been left no room for doubt as to the success of the experiment. It is alleged by the advocates of co-education that our public schools have been handicapped by the unnatural conditions caused by separation of boys and girls, which tend to produce and foster vice, and that if the unnatural conditions are taken away the school system has the power both to make the pupils good and keep them so. In a paper in the *Parents' Review* the Rev. Cecil Grant, of Harpenden, argues strongly in support of this view. Speaking after an experience of ten years, he says that co-education has no disadvantages at any age; it would be as reasonable to speak of the disadvantages of having both boys and girls in a family. Its advantages begin with the earliest school years, and are greatest during adolescence, and the succeeding years. It is argued that in a school for boys alone or girls alone risk of immorality cannot be avoided by any means, since separate education defies Nature, and renders it impossible to teach "sex reverence." Co-education, we are told, gives immunity from impure conversation; it has resulted in a wonderful improvement in manners, and an absence of the gloom which mostly pervades all monastic institutions. Association with their brothers and their brothers' friends has rendered girls less self-conscious, and given them wider interests. Association with the opposite sex has taught the boys on the other hand to be more painstaking, and has deprived them of the tendency towards vindictiveness and cruelty, which is sometimes marked in the monastically-educated boy, while they have gained in manliness and chivalry. There has been no tendency either of girls to become tom-boys, or of boys to become effeminate. Mr. Grant makes the strong assertion that if a wise system of co-education were universal, sexual immorality among young or grown up people would become extinct, while natural differences and the healthy instincts of sex would remain.

#### School Clinics.

In a leader in these pages last Wednesday the practicability of school clinics was discussed. Simultaneously with its publication there appeared in the newspapers the Report of the London County Council with regard to the negotiations which the Education Committee had been conducting with London hospitals with reference to the treatment of children. The Committee recommend as an experiment for a year that arrangements be entered into with a number of general and special hospitals, which will secure treatment of 10,000 children in respect of eye, ear, and skin ailments. This will involve an expenditure of £4,000 a year, and still leave 5,000 children not provided for. What would be the cost of providing treatment for the large classes of defects

and diseases besides those named is not specified, and the present limited scheme would need the approval of the Board of Education. Under the Education Act of 1909 the local education authority may call upon parents to pay a part or the whole cost of medical treatment, and may when necessary recover the amount summarily as a civil debt. It seems, however, a little doubtful whether the charge on the rates would be materially diminished from this source, and it remains to be seen how this suggested new impost is likely to be viewed by the public, who will be called upon to pay the bill.

#### The Health of Dublin.

IN another column we notice a letter on the health of Dublin addressed by the Medical Officer of Health to the Lord Mayor. We confess we do not quite understand why the matters dealt with might not have been included in Sir Charles Cameron's Annual Report presented a few months ago, but if it is the hope of Sir Charles by a special letter to call attention more emphatically to the evils in question, we heartily commend his intention. The evils mentioned are, indeed, well known to every one interested in the condition of the City, but they cannot be too often impressed on the mind of the public. We fear, however, that by suggesting impracticable remedies, Sir Charles Cameron weakens his case. Dwellings for the poor are very necessary, but it is absurd to suppose that in the present state of ruinous taxation the ratepayer will willingly saddle himself with another sixpence in the pound. Again, in the present state of Parliamentary business, it is impracticable to bring in a highly contentious Bill to confer additional powers on the Corporation. Some of the measures suggested by Sir Charles Cameron, such as the cleansing of lanes and courts, are already in the power of the Corporation, and by concentrating his activity in such directions Sir Charles would probably do more good than by demanding unattainable powers. The fact is, as Sir Charles Cameron shows, that the Corporation has more ample powers than it ever exercises. Until it evinces some desire to exercise these powers for the common good, the public will regard with suspicion any attempt to gain new powers.

#### Sanitation—General and Special.

IT is somewhat painful when the public mind cannot grasp the fact that, while general hygienic efforts may have had a beneficial effect in preventing a disease, say, small-pox, there may be still some value in special sanitary measures. Unfortunate as this may be with laymen, it amounts to a positive misfortune when medical men fall into the same error, and seek to belittle special work, attributing every lessening of disease to general measures, especially as, after all, general preventive measures are a collection of what were once special measures in their own particular spheres. A recent number of a well-known review has lent its columns to the discussion of the relative value of general hygiene, and the special

prevention of Malta fever by avoiding local goat's milk. Be the merits or demerits of the various contentions what they may, it is to be regretted that the public mind should be assisted by a doctor of medicine to doubt honest medical endeavour. In the case in point, however, the weight of evidence in favour of there being efficacy in the special measures, namely, the elimination of goat's milk, is overwhelming; at the same time there is little doubt that general hygienic procedure in Malta, as elsewhere, adds its quota to the final result.

### The Kingston Medical Officer of Health.

IN these columns, on October 20th, was described the hard case of Dr. Collins, the Kingston Medical Officer of Health, whose salary the Town Council, without assigning any reason, was proposing to reduce by the sum of £35 a year. A movement was on foot to promote a testimonial to Dr. Collins to show the appreciation of his services by the public during the sixteen years' tenure of his office. A memorial signed by all the medical men in the district was sent to the Council expressing their high appreciation of Dr. Collins's services to the borough, and their hope that his salary would be restored to the former amount of £500. The Council, however, declined to receive the memorial, an act which we are told is much resented in the town. The Local Government Board has now asked the Council to reconsider its action in reducing the salary. This action the Board takes as an expression of the Council's displeasure at the independent character of Dr. Collins's reports, whilst pointing out that their policy for some time past all over the county has been to induce all authorities to pay a minimum of £500 a year to whole-time medical officers. The Town Council has met this request by deleting from the terms of Dr. Collins's appointment the reference to his giving his whole time to the work of his office, although aware that during the sixteen years he has held it he has not taken private practice. It is to be hoped that the Local Government Board will not be satisfied with this; but it must be borne in mind that they possess no power to coerce a recalcitrant authority or to prevent them from venting their spleen in a variety of other ways upon an old faithful servant trying conscientiously to carry out his duty towards the public. It is impossible to add any novel comment to this fresh example of a very common state of things. That such occurrences should continue possible is the fault of the public. They can if they choose turn out from the authorities inferior men and replace them by others not capable of sacrificing the welfare of the people to gratify their own petty personal feelings, or to serve the sordid ends of themselves and their friends. If the burgesses of Kingston can rouse themselves and develop the spirit of local patriotism, they may put an end to the present scandal, do justice to Dr. Collins, and set a much-needed example to the country. The country sadly needs teaching that unless the bulk of respectable and capable citizens will display adequate practical interest in local affairs, unless they will either undertake to serve on local bodies or take part in electing fit candi-

dates, local legislation of any kind cannot be properly administered, our democratic institutions which are putting more and more power into the hands of local bodies will fail, and the failure will involve damage, if not disaster, to the whole nation and to the Empire.

## PERSONAL.

HIS MAJESTY THE KING opened the Jubilee Extension buildings of the National Hospital for the Paralysed and Epileptic on the 4th inst. The Queen was unable to accompany the King, but sent chocolates for the little children patients.

DR. JAMESON left by the Union Castle liner *Saxon* for the Cape on the 6th inst.

MR. GEORGE H. POOLEY, B.A., F.R.C.S.Eng., F.R.C.S.Ed., has been appointed to the Lectureship in Ophthalmology at the University of Sheffield.

THE Local Government Board has asked the Kingston Town Council to reconsider its action in reducing the salary of the M.O.H. (Dr. H. Beale Collins).

MISS HALDANE, the sister of the Secretary for War, presented badges to the members of the Territorial Force Nursing Service for Yorkshire, on the 4th inst.

MR. GEORGE WILKINSON, B.A., M.B., F.R.C.S., has been appointed to the newly instituted Lectureship in Diseases of the Ear, Nose and Throat at the University of Sheffield.

DR. A. NEWSHOLME has been elected a member of the Executive Committee of the Imperial Cancer Research Fund, in the place of Dr. P. H. Pye-Smith, resigned.

DR. J. W. W. STEVENS, Walter Myers Lecturer in the Liverpool School of Tropical Medicine, has left for Alexandria to undertake an important inquiry into helminthology in Egypt on behalf of the School.

MR. HEDLEY HILL, M.D.Durb., L.R.C.P.Lond., M.R.C.S.Eng., has been appointed the Honorary Representative of the Royal Humane Society in Bristol. Dr. Hill received the Stanhope gold medal for the best rescue in 1887.

THE treasurers of the Middlesex Hospital Cancer Charity have received from Mr. and Mrs. Richard R. Hollins a further donation of £100 for the maintenance of the Richard Hollins Scholarship attached to the Cancer Research Laboratories.

AT the recent Annual Dinner of the Balneological and Climatological Society, under the Presidency of Dr. Leonard Williams, a presentation was made to Dr. Septimus Sunderland, in recognition of his long and valuable services to the Society.

MR. C. K. C. HERAPATH will preside at the annual Medical School Dinner of the University of Bristol, which will take place at the Royal Hotel, Bristol, on Tuesday, November 23rd, 1909. Sir Isambard Owen, D.C.L., M.D., Vice-Chancellor, will be the guest of the evening.

DR. CASSELLS, whose duty it was to assist at the tube-feeding of some suffragettes, had his house at Handsworth visited during the early hours of Thursday morning last, with the result that bills of the Women's Social and Political Union were pasted on the dining-room window, and lumps of coal left on the doorstep.

# A CLINICAL LECTURE

ON

## SUPPURATION IN THE ACCESSORY NASAL SINUSES. (a)

By JAMES DONELAN, M.Ch., M.B.,

Chevalier of the Crown of Italy; Laryngologist to the Italian Hospital, London.

### PART II.

In *acute attacks* it takes two chief forms:—

(1) Neuralgic pains. (2) Constant headache more or less distinctly associated with the region of the affected sinus.

(1) The neuralgic pains are not always present, but occur only at certain hours, usually towards midday, attain their acme in one or two hours, and gradually pass off. The patient is usually free from them during the night and the greater part of the day. Hajek points out that since these pains are relieved by antipyrin and phenacetin, many practitioners regard them where occurring in the course of influenza as due to an influenzal trigeminal neuritis, an opinion which he regards as absolutely untenable. On the other hand, *sic douloureux* is not usually associated with acute sinus inflammation.

(2) The other class of pains are associated with the sinus limits. These are usually constant pains in the walls of the affected sinus. They very often occur in acute empyema instead of the neuralgic pains if the case is getting worse, or especially if marked retention occurs, or if the inflammation attacks the bony wall.

(b) Headache in *chronic sinusitis* has usually a diffuse, indefinite character. Most frequently it is frontal, dull, and associated with a feeling of heaviness. Pains in the vertex and occipital pains are by no means rare. It is very rare to have face-ache with chronic maxillary empyema. On the whole, the diffuse headache of chronic sinusitis shows the greatest irregularity. It may be present in a slight case, and completely absent in long-standing cases with the most fetid secretion. In chronic ethmoidal and maxillary empyema it may be absent through the whole course of the disease. It is, however, more frequent in frontal and sphenoidal disease. One has to be on one's guard against attempting to localise the affected sinus from the subjective sensations of the patient. There is no definitely ascertained constant relation between the headache and the pathological condition that would warrant one doing so. Especially is this to be borne in mind with regard to frontal headache, as the normal frontal sinus has been opened several times in error as the result of following subjective indications too exclusively.

During exacerbations of chronic empyemata the headache usually takes on something of the neuralgic character mentioned in regard to acute empyemata. The connection of hemicrania with sinus suppuration is uncertain. It is, however, often relieved by the effectual treatment of the empyema, but is so far not known to have disappeared altogether.

(2) Secretion. The most constant and striking sign of a sinus inflammation is the occurrence of abnormal mucus, muco-pus, or pure pus. The quantity varies greatly according to the stage and intensity of the affection. It is usually most copious in the acute stage or during exacerbations. Patients have been known to use 30 or more handkerchiefs a day. A great part of it, however, passes into the pharynx, and is swallowed or hawked up.

In acute conditions it is usually more fluid, while in chronic it tends to form lumps or crusts. There are, however, many exceptions to this. Sometimes the pus forms ill-smelling, cheesy masses, due to fatty degeneration of the pus cells. This caseous degeneration occurs most commonly in the pus from the maxillary sinus, less frequently in the frontal, while only a

few rare cases have been reported in connection with the sphenoidal. There is usually only a slight purulent odour. The pus from the maxillary sinus is always fetid in empyema due to carious teeth or to breaking down of a tumour. Pus from the ethmoidal cells and the sphenoidal sinus has the greatest tendency to form evil-smelling crusts giving rise to the symptom of ozæna, otherwise to the condition so often described as fetid atrophic rhinitis. While fetid crusts are highly significant of ethmoidal or sphenoidal disease, it should be borne in mind that fetid crust formation may occasionally result from maxillary and frontal empyemata.

(3) Disturbances of smell. As a rule, the olfactory sense of the patient is weakened in consequence of changes in the olfactory membrane. This is especially the case in disease of the sphenoidal and ethmoidal cells. Even in an early stage, and before any serious change in the perceptive mechanism has been induced, the pus is deposited in scales, the membrane being covered, so to speak, with an impermeable varnish which prevents access of odoriferous particles. Perception is usually recovered even in very long-standing cases on draining the empyema. There are, however, many instances in which, owing to advanced degeneration of the olfactory membrane, this does not take place. Subjective cacosmia: The perception from time to time of an evil odour without external cause is very significant of sinus trouble, especially in the maxillary and sphenoidal sinus.

Gustatory anæmia or loss of taste is also a partial consequence of loss of smell.

(4) *Changes from secondary disease of the upper respiratory tract.*—The chief is interference with nasal respiration through irritation products induced by the pus, such as degeneration of mucous membranes, hypertrophies of all kinds, including polypi. Several cases of maxillary empyema have been recorded, in which, as during exacerbations, when the sinus was gorged with pus, the middle turbinal swelled up so as to block the upper part of the nasal passage. This was, of course, due to the intimate vascular connection between antrum and turbinal. Of true hypertrophies I have myself seen a somewhat remarkable example, of which the details will be given elsewhere. The patient suffered from severe and frequent epistaxis, a large, sharp, thorn-shaped spur had grown out from the septum, apparently as the result of continued flow of pus from the middle meatus. The point was impacted in the posterior part of the inferior turbinal, causing a pressure ulcer from which the bleeding took place. The spur was removed, a maxillary empyema of long standing was located and drained, and a good recovery took place.

Repeated attacks of follicular tonsillitis may be occasioned by pus from the nasal sinuses entering the crypts of the tonsils.

Time does not permit me to mention more than the reflex asthmas (whether polypi are present or not), the catarrhal affections of the pharynx, larynx, and lower respiratory tract. Very often these diseases have become chronic long before the primary cause is discovered in an old sinus empyema.

(5) *Digestive Troubles.*—An evil taste in the mouth is often noticed in the mornings from pus flowing into the pharynx during the night. Repeated attacks of vomiting may result from the increased irritability of the pharynx, and may cause various forms of dyspepsia. Cases have been reported by Kuhnt and others. Quite recently a case of defective secretion of

(a) Delivered at the Medical Graduates' College and Polytechnic, London, Oct. 5th, 1909.

hydrochloric acid has been reported by Scherer, in which a return to a normal condition of the gastric fluid followed evacuation of a maxillary abscess.

(b) General symptoms: The general symptoms include these phenomena which cannot be directly attributed to the sinus disease or the secretion, but are rather the expression of a reaction of the whole organism. They are:—(1) Fever; (2) congestion; (3) depression. (1) Fever in the inflammatory sinus affections is usually indistinguishable from that of the exciting cause—*influenza*, *diphtheria*, etc. In chronic empyema it is generally absent. When it occurs it is usually a sign that the disease process has attacked some neighbouring structure or organ, and is often a warning of the onset of grave complications, orbital or cerebral.

(2) The congestive symptoms show themselves as general vascular excitement, increased frequency of pulse, injection of conjunctivæ, *muscæ volitantes*, intolerance of alcohol and tobacco, irritability and moroseness of temper.

(3) Amongst the depression symptoms that have been observed in definite association with sinus trouble, and which have been relieved by successful treatment of the empyema, are: slow pulse, probably from reflex vagus irritation; this has also been observed to take place in forcible douching of the maxillary antrum; loss of inclination to work; sense of early fatigue; indolence. These last, of course, have significance only in the case of patients of previously active habits. The inability to work is often the result of inability to sleep. The depression is always more marked if there be headache, and this is, as we have seen, more common with frontal empyema.

The mental activity of such patients diminishes, and there are often somnolence, indolence, and hypochondria.

The occurrence of sinus empyema in the young hinders mental development, while in adults melancholia has been observed to supervene frequently in persons afflicted with *ozæna*. I saw myself some years ago a suicidal melancholic whose *ozænic* and mental symptoms dated from an attack of *influenza*, but who has remained well since his frontal and ethmoidal sinuses were adequately drained.

Symptoms from complications omitted: I have entered at more fully into the local and general subjective symptoms than, perhaps, their value as aids to diagnosis would have warranted. It must be admitted that they only serve to awaken a suspicion that sinus trouble may exist, and in so far they are useful. It is only very rarely indeed that one can say that there is inflammation or suppuration of any individual sinus merely from the patient's account of what he feels. The recognition of the relation of these symptoms to sinusitis may, however, serve to direct attention to the influence on the entire organism of what in plain terms we may call "an abscess in the head," and may make us pause in our selection from the various paths to which they may misleadingly point. It should, at any rate, be borne in mind that these symptoms may very often be evidence of a common trouble like sinusitis, rather than of the rarer affections with which they are sometimes also associated, and that no diagnosis should be made until a thorough examination of the nasal cavities has taken place.

**Diagnosis.**—The diagnosis of sinus suppuration can then be made with certainty only as the result of a painstaking rhinoscopy. I have already alluded to the doubtful assistance rendered by transillumination, and the same may be said of skiagraphs. We will now proceed to make the diagnosis by intra-nasal examination alone, without the aid of symptoms of any kind. In a given case of, say, unilateral purulent nasal secretion, the problem is to find the source of the pus. It may not come from a sinus at all, but may be the result of irritation and retention caused by a foreign body, a rhinolith, or a syphilitic sequestrum. The pus may all go down the pharynx, as in my case of septal spur and epistaxis, owing to occlusion of the anterior part of the middle meatus. The first step is to remove all visible pus either with a douche or tampons. If there are crusts these are better not removed with a

douche at first, but by forceps, as on gently detaching them a stream of pus may issue from a point close to the source, and serve as an indication. If there be no foreign body or similar cause of intra-nasal supuration, the pus probably comes from a sinus. Having thoroughly cleansed all the nasal passages, the recurrence of the pus should be looked for first in the middle meatus as more likely, and next in the olfactory fissure. In other words, we must note on which side of the middle turbinal it reappears.

The pus may come from a sinus or from a lesion of the mucous membrane. The rapidity with which the pus recurs helps us here, though it tells us nothing as to which or how many sinuses may be affected. If it recurs very slowly and in small quantity, there is probably only a lesion of the mucous membrane, but if it wells out after some seconds or even minutes, it is strong evidence that it has been pent in some sinus, as in a reservoir. It may then be taken as a general rule that the rapid recurrence of pus in the olfactory fissure or middle meatus, after thorough cleansing, is reliable evidence that it must come from one or more of the sinuses. To this there are some exceptions, as, for instance, when the sinus secretion is unusually small; also it is obvious that in the case of closed empyemata no secretion can take place. We have next to consider whether the pus comes from one or more sinuses, and which of them. We may divide the sinuses not only with reference to their own position, but especially to that of their outlets into two sets. The first, the anterior set, includes the frontal and maxillary sinuses, and the anterior ethmoidal cells. The outlets of these are all hidden outside the anterior end of the middle turbinal in or in the immediate vicinity of the hiatus semilunaris.

The posterior set includes the posterior ethmoidal cells and the sphenoidal sinus opening into the superior meatus. It is obvious that pus from the anterior set must follow a very different course from that flowing from the posterior. With reference to the middle turbinal, pus from the anterior set appears outside it in the middle meatus, while that from the posterior set is seen between the middle turbinal and the septum in the olfactory fissure. Suppose we have so far shown that there is suppuration of one of the anterior sinuses, we have next to decide which of them. Now the maxillary is the most frequently affected of the anterior set, so we begin by excluding that. As the normal ostium is placed in the highest part of the cavity when the head is erect, we bend the head down between the knees with the suspected side upwards. If pus reappears in the middle meatus during this manœuvre, it must come from the maxillary antrum. If it is from the frontal or ethmoidal cells, it will reappear only in the erect position. The absence of pus after bending down does not prove, however, there is none in the antrum. The next step is to try and find a possible accessory ostium in the middle meatus, and to wash out the cavity by means of a bent cannula. If there is no such opening, a further attempt should be made to wash out through the normal ostium in the hiatus. If in either case the fluid returns mingled with pus, we have either a maxillary empyæma or a condition of pyosinus. If all these methods fail, our next step is to make an artificial opening. Until quite recently, puncture through the alveolar process was the usual method, either through a vacant alveolus or through a vacancy which it was felt necessary to create in the interests of the patient. As a method of diagnosis it was objectionable on the ground that it exposed a possibly healthy sinus to the risk of infection from the mouth, while as a means of treatment it is on similar grounds being rapidly superseded by modern intra-nasal methods. Personally I find that puncture through the inferior meatus as low down as the bony wall will easily allow, or through the middle meatus just above the attachment of the inferior turbinal, if the patient be kept in a recumbent position during this part of the examination, will enable one to aspirate any pus that may be in the cavity with a suitably curved cannula. The puncture should be made at a point corresponding to the second molar, or the space between it and the third. If after this pus appears in the middle meatus in the erect

position, it must come from the frontal sinus or the anterior ethmoidal cells.

The frontal being the easier of access, we next proceed to examine that.

Test puncture being here impossible we have to rely chiefly on the probe, as the douche cannula cannot always be used. At this stage of the examination, which may occupy several sittings spread over sometimes two or three weeks, it is usually necessary to remove the anterior half of the middle turbinal. Even then the hiatus may not be accessible on account of hypertrophies and polypi, all of which may have to be cleared before further progress can be made.

Supposing that we have at last got a probe into the infundibulum. If it is only a thin one it is useless to think of using the cannula to wash out pus from the sinus. We should use as large a probe as will go into the passage easily, introduce it slowly and draw it back rapidly, but not out, a few times so as to make it act as a piston. This and the *vis a tergo* will help to make the pus well up around the instrument if any is present. If it has not been found in this way, and if it has not been necessary to remove the anterior end of the turbinal, and pus now again appears in the middle meatus, it can only come from the anterior ethmoidal cells. The removal of the anterior part of the turbinal and direct probing of the ostia is of course the more reliable method, and should always be followed in doubtful cases.

In going over this method of differential diagnosis I have endeavoured to keep before us that pus found in the maxillary sinus need not be secreted in that cavity. We may have the condition known as pyosinus. Here our method fails, for we have as yet no certain means of diagnosing this condition except from the results of treatment of the frontal or ethmoidal cells. If after clearing the hiatus and draining the upper cavities pus is still found in the antrum, it is in all likelihood secreted there. If, on the other hand, it is no longer present, the previous condition has been one of pyosinus.

We finally take suppuration in the olfactory fissure. This may, as in the instances already mentioned, be due to mere recent catarrh, syphilis of bone, or a foreign body. Having excluded these and decided the pus must come from the sphenoidal or posterior ethmoidal cells further progress is conditioned by the width of the fissure. If the fissure is wide and not obstructed in any part by the middle turbinal or a deflection of the upper part of the septum it is possible in a great many cases to see the sphenoidal ostium. In such cases the diagnosis offers little difficulty. The secretion lies either in the naso-pharynx or the posterior part of the nose. When the pus and the crusts that have usually accumulated have been removed it should be possible to see that pus is in or issuing from the sphenoidal sinus of the side under examination.

The probe can be passed easily into the ostium and can usually be advanced until the distance from the inferior nasal spine is about 7 cm., usually between 8 and 9. In some cases when the sinus extends into the basilar process the distance may be as much as 10½ cm. As in the case of the maxillary sinus, we have to bear in mind that the sphenoidal may also act as a reservoir for pus from a higher placed cavity. We have therefore only proved that there is pus in the sinus. Leaving that question for later decision, we proceed as in the anterior sinuses to thoroughly cleanse the sphenoidal sinus and the olfactory fissure and see whether the pus reappears quickly and where. Pus now reappearing must come from the posterior ethmoidal cells. It is a good plan, also recommended by Hajek, to do as I suggested for the examination of the maxillary sinus, and place the patient lying down or with his head well bent back, as in this way the flow from the ethmoid is hastened and will often be seen not only in the fissure, but also running down over the anterior sphenoidal wall. We have now gained the knowledge that suppuration is taking place in the ethmoidal cells, and that there is pus in the sphenoidal. Suppuration may be going on in both, however, or the sphenoidal may be only filled with pus from the ethmoid.

In order to decide this we must temporarily separate them by plugging the sphenoidal ostium either as it stands or after enlargement by Hajek's hook or other suitable curette. If the ostium lies so far out in the sphenoidal recess as to be probed with difficulty, the recess itself should be plugged. The tampon should be left in place for from 12 to 24 hours. Pus from the ethmoid will now cover the anterior aspect of the tampon, while that secreted in the sphenoidal will be received posteriorly. Moreover, on removal of the tampon the pus from the sphenoid will well out quickly. It may be necessary to repeat this process two or three times before coming to a definite decision. Another advantage of this method is that it enables us not only to see whether one or both sinuses is affected, but also to settle the question of pyosinus. It has been suggested that pyosinus of the posterior ethmoidal cells from the sphenoidal may take place, but Hajek, who is the greatest living authority on these matters, has never seen a case, though he does not deny its possibility. Though the sphenoidal sinus may and is often the site of independent empyema, this is not the case with the posterior ethmoidal cells when they suppurate there is usually simultaneous, or shortly following, suppuration of the sphenoidal sinus or sinuses.

Only one point remains for consideration, and that is the procedure in cases where the olfactory fissure is so narrow as to afford no view of the sphenoidal ostium. Here we proceed in a manner analogous to that employed with the anterior sinuses, and remove the posterior part of the middle turbinal with scissors and snare. If the anterior part or lower border still obstructs the view, these must also be suitably shortened. Needless to say, all polypi must be removed from the superior meatus, and if necessary a deflected septum must be corrected. It should be noted here that it is often possible to wash out the sphenoidal sinus even when it cannot be seen on account of a narrow olfactory fissure. The weight of experience is, however, against this as a means of arriving at an accurate diagnosis, and as successful treatment of suppuration in the posterior sinuses will need as full a view of the seat of the trouble as possible there is no valid reason why the removal of the necessary amount of middle turbinal should not be carried out to settle the differential diagnoses. Having gained access to the space in this way, the diagnosis between the two possible sources of the pus is made as described in connection with the wide olfactory fissure.

In this rapid survey of the general features of sinus suppuration, many points that will at once suggest themselves by their absence will occur to every one. It would not have been possible, I think, to bring them in, even if time allowed, without trenching on the subject matter of others, who will doubtless discuss the individual sinus diseases and their treatment in due course.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Robert J. Rowlette, M.D., Pathologist to Dr. Stevens' Hospital, and to the Rotunda Hospital, Dublin. Subject: "Vaccine Treatment in General Practice."

## BRADSHAW LECTURE.

### DARWINISM AND MEDICINE. (a)

By JAMES ALEXANDER LINDSAY, M.A., M.D.,  
F.R.C.P.,

Professor of Medicine in the Queen's University of Belfast, Physician to the Royal Victoria Hospital, Belfast.

MR. PRESIDENT,—I trust I may with some propriety, in this year of the Darwin centenary, ask you to consider with me the significance of Darwin's great discovery for medical thought and practice. The subject is large, and can on this occasion be dealt with only in outline. The field which I shall ask you

(a) Delivered at the Royal College of Physicians, London, on November 2nd, 1909.

to traverse is a well-trodden one, but I believe its fruitfulness is not yet exhausted. Darwin's work on "The Origin of Species" contained, as Helmholtz said, "an essentially new creative thought," a thought, I venture to add, which is still fertile, still seminal, still full of suggestion and guidance for all whose labours lie in the field of biology.

The relation of the science and art of medicine to the higher thought of the day must always be a matter of interest and importance. Medicine is coloured by that thought; its postulates, prepossessions, and theories are modified by it; in its degree it contributes to that thought. When we get from the facts of science to the truths of science, to emphasise a pregnant distinction, our thinking is modified stimulated or deflected to an important extent by the intellectual atmosphere in which we live. A notable instance in point is afforded by the Father of Medicine—Hippocrates. In the Homeric poems everything is miraculous. The storm, the sunshine, shipwreck, plague, blight, sickness, victory, defeat—everything is due to the direct interposition of supernatural powers. "Every event," as the late James Adam said, "is a theophany." The conception of natural law has not yet arisen. How different is the atmosphere of the works of Hippocrates. Here, amidst much that is crude and empirical, there is a genuine recognition that in the field of disease events follow a natural sequence, that effects are proportionate to causes, that order reigns, and that our business is to investigate that order. Between Homer and Hippocrates had intervened the great school of the Ionian physicists, from Thales to Democritus, physical science had seen its dim and feeble dawn, the lineal succession was opened which was one day to include the names of Galileo and Copernicus, of Liebnitz and Newton, of Darwin and Wallace. The comparative failure of the successors of Galen to advance the art of medicine, and the barrenness of our art during the many hundred years during which their influence reigned supreme, were due in large measure to the false philosophy which lay at the root of the Galenic system, to the predominance of metaphysical theory over observation and experiment. The rapid advance of medical science in modern times has coincided with the progress of physical and biological science in general, in part because science furnishes medicine with instruments of precision and methods of research, but perhaps even more because it creates the atmosphere in which medicine can flourish and develop. The reaction of one branch of science upon another branch at the present day is both potent and prompt.

I need not inform you that the conception of evolution existed long before Darwin, and goes back to the very dawn of science. It is said to occur in the sacred books of the Vedas. It was the central thought of the philosophy of Heraclitus. It is found in the works of Aristotle, and we can trace it through a long succession of thinkers, including Bacon, Descartes, Leibnitz, Hume, Kant, Goethe, Buffon, Geoffrey St. Hilaire, Erasmus Darwin, and Lamarck. It is interesting to note that one of the most notable precursors of Darwin was a member of our own profession, Dr. James Cowles Prichard, of Bristol. Writing in the year 1826 Prichard clearly recognised the existence of organic evolution, he fully apprehended that domesticated races of animals and plants have been produced by selection by man, and not by the influence of environment; he recognised the operation of Natural Selection, though he misinterpreted its range and importance; and, most curious of all, he recognised the difference between acquired and congenital characters, and argued for the transmissibility of the latter and the non-transmissibility of the former—a view reached independently half-a-century later by Weismann, and now usually associated with his name. Darwin did not discover Evolution. He discovered its leading law, and by a long series of observations, experiments, and reflections, unparalleled in the history of science, he converted the brilliant guesses of earlier inquirers into an assured truth and an established principle. "We claim for Darwin," says Alfred Russel Wallace, "that he is the Newton of natural history, and that, just as surely as that the discovery and demonstration

by Newton of the law of gravitation established order in place of chaos and laid a sure foundation for all future study of the starry heavens, so surely has Darwin, by his discovery of the law of Natural Selection and his demonstration of the great principle of the preservation of useful variations in the struggle for life, not only thrown a flood of light on the process of development of the whole organic world, but also established a firm foundation for all future study of Nature." The conception that the organic world is the scene of an incessant struggle, of a keen vital competition, in which the fittest survive, *i.e.*, the fittest for their environment in the capacity to obtain food, resist their enemies, and propagate their kind, while the unfit perish, has been recognised as the fundamental law of life, and the demonstration of this principle we owe to Darwin and to Wallace. As Weismann says, this principle "has become the basis of the science of life," it "has conquered the world," and has become so inwrought in the texture of our thought that it is now practically impossible to think of any biological problem except in terms of evolution. That any of the fundamental features of the Darwinian doctrine have been subverted by fifty years of inquiry and controversy is not, to my mind, a tenable proposition. It is true that some of the subordinate features of that doctrine remain open questions—how far, for example, use and disuse have operated in producing organic changes, what weight is to be assigned to the influence of the environment—a point upon which careful readers of the works of Darwin will see that his mind wavered from time to time—what is the precise significance and area of operation of sexual selection, whether acquired characters are inherited or not, how far the Mutationism of De Vries and others operates instead of slow and almost imperceptible change. On these points finality has not yet been attained, but their solution—whatever it may be—will not invalidate the Darwinian doctrine. The general tendency of inquiry since Darwin's time has been, upon the whole, to strengthen the claim of Natural Selection to be regarded as the great law of organic life, to show how wide its range, how subtle its operations, and to minimise the importance of other factors. To take an example—at first sight nothing can be more obvious than to attribute to the effect of disuse the loss of sight by fish, crabs and rats inhabiting the dark caves of Kentucky and Carniola. But another view is at least tenable. When, owing to the absence of light, the faculty of sight ceased to be of utility to these creatures, Natural Selection, of which the function is to keep every organ which is of use to any creature up to the mark, ceased to operate, and it is a fundamental law that any organ withdrawn from the conservative action of Natural Selection tends to degenerate. The controversy especially associated with the name of Weismann, whether acquired characters are inherited or not, is one of vast and far-reaching importance for practitioners of medicine. Weismann, as you are aware, holds that in all organisms there are two kinds of plasm, the somatic and the germinal; that the permanent germ plasm passes unchanged through a series of generations, and is not affected, or but little affected, by environmental influences, which affect the somatic plasm; that modifications produced upon the somatic plasm by the environment and by use or disuse are practically limited to the individual and not transmitted to the offspring, and that hence no characters except those predetermined in the germ are available for evolution. This question is too large to be discussed at any length on this occasion. Medical opinion has been to a large extent opposed to the views of Weismann, but it must be admitted that he has succeeded in throwing great doubt on the transmissibility of acquired characters, a doctrine which Darwin assumed as too obvious to require demonstration. Most of the supposed cases of such transmission are apparent rather than real. Syphilis seems a crucial case in point, hereditary syphilis being one of the most familiar of phenomena. But it is now practically certain that this is not a case of inheritance at all, in the strict sense of the term, the true explanation of

the facts being an ante-natal infection of the ovum, usually from the maternal side. Whether tuberculosis is ever directly conveyed from parent to child is still doubtful, but if such transmission were proved the most probable explanation would be the direct inoculation of the embryo, and not inheritance. To disprove Weismann's doctrine we should require to show that mutilations or the results of training, exercise or education, or acquired diseases, re-appeared in the offspring as the result of heredity. This has not been hitherto conclusively shown. The problem is one which has great interest for us, and medical observers might contribute to its solution. May I suggest a case in point where evidence from the side of medicine might be available? In a certain proportion of cases neurasthenia is brought on by over-study, anxiety, overwork, want of sleep, excess of some kind, in persons where no congenital tendency to nervous disease can be suspected. Is such neurasthenia transmitted either as neurasthenia or some allied condition? The question is worthy of attention, and an answer ought to be possible.

Darwin as a scientific worker presents us with a model good for all time, and worthy of admiration and imitation. "My success as a man of science, whatever this may have amounted to," he tells us, "has been determined by complex and diversified mental qualities and conditions. Of these the most important have been a love of science, unbounded patience in long reflecting over any subject, industry in observing and collecting facts, and a fair share of invention and common sense." In another place he says:—"Whatever I have done in science has solely been by long pondering, patience, and industry." This is altogether too modest an estimate. Darwin, in point of fact, possessed in a supreme degree two faculties rarely present in perfection in the same individual—viz., immense industry and accuracy in the accumulation of facts, and a daring originality of speculation, coupled with much caution in drawing any final conclusions. He had the power of keeping any subject more or less before him for a great many years. He was an indomitable theoriser, and held that "without speculation there is no good and original observation." Again he says:—"I cannot resist forming a hypothesis upon every subject." The essential fairness and integrity of his mind is shown by the following passage:—"I had also during many years followed a golden rule, namely, that whenever a published fact, a new observation or thought came across me which was opposed to my general results, to make a memorandum of it without fail and at once, for I have found by experience that such facts and thoughts were far more apt to escape from the memory than favourable ones."

May I suggest that in much of the above there is a wholesome lesson for ourselves? That we should be diligent, patient, and thorough in the collection of facts goes without saying. That we should keep those facts for long periods, even for years, before our minds, before drawing, still less publishing, our conclusions, will seem a hard saying to the contributors to periodical medical literature. Perhaps, indeed, such a rule is a counsel of perfection, hardly possible to the average man. But I would ask you to note the high place assigned by Darwin to theorising and speculation in scientific work. This may seem a dangerous doctrine, but I am convinced that it is a sound one. Medical science is to-day overweighted by the accumulation of a vast array of more or less crude and isolated facts. What we need is the illuminating generalisation, the daring hypothesis, to co-ordinate facts hitherto out of relation with each other, to give perchance to science a new *organon*, to light the way to fresh fields of inquiry and discovery. It is the presence of this element of underlying theory or law which lends so much attractiveness to the work of Pasteur and Lister, of Koch and Metchnikoff, of Ehrlich and Wright. The bold hypothesis lights up the dark ways of Nature, illumines the road already traversed, sheds light on the pathway which lies ahead.

Before proceeding, after the foregoing more or less preliminary observations, to apply the principles of

Darwinism to man in health and in disease, I may be permitted to remind you of the fundamental Laws of Growth which must guide us in our inquiries. These laws might be stated as follows:—

- (a) The Law of the Perpetuation of Species or of the Unity of Type.
- (b) The Law of Variation.
- (c) The Law of Reversion.
- (d) The Law of Atavism.
- (e) The Law of Correlation, whereby when one organ varies other organs tend to vary also.
- (f) The Law of Compensation or Economy, whereby increase of growth of one organ is accompanied by diminution in growth of another organ.
- (g) The Law of Sexual Selection.

We might summarise the foregoing laws as follows:—The general tendency in all living organisms is that the child shall resemble the parent in specific characters—i.e., that the unity of type shall be preserved. But variation from type is always present to a greater or less degree. Darwin thought that variation was largely due to changed conditions of life. Weismann believes that sexual reproduction is the chief cause of variation in the higher animals, including man, and Wallace shares this view. Variation is accompanied by a tendency to revert to type. Hence, notable departures from type tend to die out, but to this law there are many curious exceptions—e.g., the Ancon sheep, and the numerous "sports" amongst plants which have given rise to permanent new varieties. Atavism is the law whereby the child sometimes resembles the grand-parent or the great-grand-parent more than the parent. It may be regarded as a special case of reversion. By the law of correlation we mean that principle whereby when one organ varies another organ varies, the two organs not always being related in function. Thus, white cats with blue eyes are always deaf. In certain breeds of cattle, colour and susceptibility to the attacks of flies are correlated. By the law of compensation, or economy, we mean that principle whereby nutriment required by the overgrowth of one organ is withdrawn from another organ. It is probably in consequence of this law that the highly specialised reactions of the nervous system developed in an advanced stage of civilisation are accompanied by a decline in the birth-rate. Finally, sexual selection is undoubtedly a factor, although much uncertainty exists as to its extent of range and importance. The comparative absence of hair from the human body, especially in the female sex, has been attributed with much probability to sexual selection.

#### DARWINISM AND NORMAL HUMAN STRUCTURE AND FUNCTION.

Man is a member of the animal series, and it is reasonable to expect that the ordinary laws of evolution would be exemplified in his structure and in his functions. This we find to be the case. The body of man is built upon the same lines—bone for bone, muscle for muscle, artery for artery—as that of the higher apes. The comparatively few distinguishing features of the human organism have relation to three points—viz., the assumption by man of the erect posture, his acquisition of special manual dexterities, and his higher cerebration. The foot, the hand, and the fore-brain are almost the only points with regard to which the human body differs essentially from that of the quadrumana. Evolution accounts easily and adequately for these differences. Let us look at a few points less obvious than these. Why, out of every score of human beings, are about 19 right-handed and 1 left-handed? On any creationist hypothesis this question admits of no plausible answer, but evolution suggests a highly probable explanation of the mystery. We may fairly assume that as man developed and his functions became more specialised, it was necessary that certain parts of his structure should acquire special dexterities, and that it was by the law of economy that these dexterities were concentrated upon one limb instead of being shared by both. Hence were developed the special manipulations of the right hand. But the law of variation, above-mentioned, would suggest that in a matter of this kind evolution would not act with undeviating uniformity, but would

admit of certain departures from type. And so we find, as we might have anticipated, that about one person in 20 is left-handed. That the special dexterities of the right hand are not innate and predetermined, but the result of development, is shown by the fact that the left hand contains potentially the same aptitudes as the right, and these aptitudes can be successfully developed when the right hand is lost as the result of accident or disease.

Why are the speech centres in right-handed people located on the left side of the cerebrum? The most probable explanation, first suggested, I believe, by Moxon, is that by the same law of economy it was in the interest of the developing organism that the centres presiding over the mechanisms of speech—the precise significance and mode of operation of these centres is not here in question—should be located in one, rather than in both, hemispheres. It is entirely in accord with this theory that the right side of the cerebrum should contain potential speech centres, and that these should be capable of successful and adequate development when the centres on the left side are destroyed by disease. It is, also, quite in line with evolutionary doctrine that the same side of the cerebrum should preside over the fine manipulations of the right hand and the complicated motor mechanisms of speech.

Why are the teeth so often crowded together in the human jaws that the removal of some of them is often a necessity in early life? Evolution affords the probable clue. There are good grounds for concluding that the human jaws are undergoing a progressive diminution in size. This diminution should be accompanied by a corresponding diminution either in the size or number of the teeth, but it is quite in accord with experience in other departments that the two processes should not proceed *pari passu*. Apparently, the diminution in the size of the jaws has outrun the diminution in the size or number of the teeth, and hence the overcrowded state of the jaws which we know to be common. This explanation is adequate and probable, although it might be argued that the teeth are of less utility to man now than in earlier ages, and are hence partially removed from the operation of natural selection.

Many of those whom I address must sometimes have reflected over the curious and apparently clumsy arrangement whereby our food and drink, before entering the gullet, have to pass over the entrance to the air-passages, involving a slight but appreciable risk of foreign matters finding their way into the lungs—a risk slight in health but sometimes serious in disease. The explanation suggested by evolutionary law is that the lungs have been developed from the swim-bladder of an unknown progenitor, and that an organ originally adapted for flotation has been developed as an organ of respiration. The relation of the swim-bladder to the gullet would not have involved the same risks as the relation of the gullet to the air passages. If we accept the alternative view of the origin of the lungs—viz., that they have been developed from a pair of gill clefts, the same explanation will apply.

Why is the septum between the auricles of the heart so imperfect that the passage of blood from one chamber to the other is only just obviated in the normal individual, while patency of the foramen ovale is one of the commonest of malformations? May it not be that we have here an example of imperfect and not yet completed development? May we not expect that the present valvular arrangement for preventing the flow of blood from one auricle to another will in the course of time, under the influence of natural selection, be converted into a permanent and complete septum?

*Darwinism and Rudimentary Organs.*—Perhaps on no subject has evolution thrown a more welcome or a more satisfying light than upon the significance of rudimentary organs. At first sight, nothing can be more puzzling than that there should be in the human body certain organs which are functionally useless to the individual. Of such organs we have the following:—

(a) *The panniculus carnosus*, corresponding to the

muscles which move the skin in the lower animals. There are some persons who possess the power of moving at will the skin of the scalp and other parts, and I believe the music halls once possessed an artist who earned an honest livelihood by exhibitions of his power to throw plates and other articles from his head by contractions of the scalp muscles.

(b) The ear muscles, functionally inactive in most individuals, but in exceptional cases capable of causing movements of the pinna, suggestive of the great importance of the movements of that organ to the lower animals.

(c) The animal ear-point, a projection upon the outer fold of the ear present in some persons and corresponding in position to the pointed ear of many animals.

(d) The rudimentary nictating membrane, or *plica semilunaris*.

(e) The vermiform appendix, functionless in man, but of great importance in some of the vegetable-feeders amongst the lower animals.

(f) *The foramen supracondyloidean.*

In addition to the above, there are certain organs which seem in process of becoming rudimentary and functionless. Cutaneous hairiness is no longer of service to man, and will probably disappear under the operation of natural selection, perhaps assisted by sexual selection. The third molar or so-called wisdom teeth are probably becoming functionless. They pierce the gums late, or in some cases not at all, and they are prone to early decay. It seems probable that the sense of smell, no longer of much practical importance to civilised man, and hence removed from the action of natural selection, is becoming rudimentary. The human toes, with the exception of the great toe, which is of service in maintaining the upright posture, being no longer organs of prehension, and almost functionless, are undergoing elimination.

Rudimentary organs present no difficulty to the evolutionist. They are simply belated survivals of organs once functionally important to the race, but now on their way to extinction and disappearance. No longer under the conserving influence of natural selection, they are very prone to vary and to become the seat of disease. We see this law well exemplified in the case of the vermiform appendix, which is both highly variable in structure and very subject to disease.

It has been suggested that the many feet of the human intestine are simply survivals from a herbivorous progenitor, and of no service to a mixed feeder like man. It has even been proposed that the aid of surgery should be invoked to curtail some of its superfluous folds, which, it is argued, are not only useless, but actually a source of danger. On such a delicate subject I prefer to express no opinion. Modern surgery does not need to be stimulated to fresh fields of enterprise—least of all by a physician.

The bearing of evolution upon physiological processes opens up a wide field for reflection and speculation. We are so apt to regard these processes as fixed and final, while in reality we should regard them as fluid, variable, undergoing a process of adaptation rather than as completely adapted, imperfect, but under the influence of natural selection tending towards perfection, or in some cases, perhaps, exhibiting traces of reversion. The phenomena of digestion, for example, will appeal to our intellect and imagination very differently, according as we regard them as ultimate and final facts, or as part of an evolutionary process. Man has gone through many phases in the crucial matter of his food, and it is likely that he has still in this department a journey to go. Perhaps it might savour of irony to suggest that vegetarianism is a case of reversion to the habits of remote herbivorous ancestors, but the idea is one worth thinking over. When we are urged to lessen our consumption of butcher's meat and rely more upon nuts and salads, the question arises how far carnivorous habits are for man in the natural line of development, how far he should regard himself as essentially a mixed feeder, how far reversion to the dietetic habits of earlier ages would be a gain or a retrogression. The really illuminating thought amongst these somewhat difficult problems is that the

habits of man are not predetermined and final, but the result of countless generations of evolution; that they are neither wholly good nor wholly bad; that, on the one hand, they are worthy of respect as having stood the test of an immense experience, while, on the other hand, they are almost certainly destined to important modifications in the future. In this case, however, as always, natural selection and adaptation to the environment will be the guiding principles to which man in his arduous march through time will be compelled to conform.

(To be concluded.)

## NOTE ON NATURAL HISTORY AND DIAGNOSIS OF CIRRHOSIS OF THE LIVER,

WITH REFERENCE TO THE VALUE OF THE TALMA-DRUMMOND-MORISON OPERATION. (a)

By W. B. WARRINGTON, M.D., F.R.C.P.Lond.,  
Physician to the David Lewis Northern Hospital and to the Eye and Ear Infirmary, Liverpool; Lecturer in Clinical Medicine in the University.

You are no doubt familiar with the main argument of this note: the differentiation in clinical diagnosis between uncomplicated cirrhosis of the liver and chronic simple peritonitis with perihepatitis.

Yet, it may bear a little consideration, for the diagnostic difficulties at the bedside can only be surmounted by precise pathological knowledge, and this must form the basis of any rational views as to the indications and contra-indications for the Talma-Morison operation.

The diseases that constantly come up for consideration in this class of case are cancer, cirrhosis, perihepatitis, and syphilis. They are not so very frequent: of my last 1,000 hospital patients, about 30 suffered from these diseases. Dr. Hale White, who has specially, in England, written on these matters, finds that 4 per cent. of his patients suffered from carcinoma, cirrhosis, and gall-stones. I find that cancer and cirrhosis in my series were of about equal frequency; then comes chronic peritonitis with perihepatitis and syphilis. These are mostly diagnoses based on post-mortem results, or equally certain evidence in the case of syphilis.

I shall not consider cancer, except to say that in

the diagnosis may be difficult or even impossible, at least until the fluid is withdrawn.

I must, however, emphasise the importance of always considering syphilis: indeed, Rolleston himself, a high authority, says that medical treatment, *i.e.*, by iodide of potash, should constantly be used for the

FIG. 2.—C. (high power). Pericellular cirrhosis, such as is seen in syphilis, but sometimes in a rapidly advancing cirrhosis.

purpose of excluding any possible syphilitic disease of the liver. I have seen a typically gummatous liver and spleen in an old lady of 56, who had brought several healthy children into the world. Upon admission she was ill and cachectic, with severe abdominal pain, ascites, a large liver, and a mass in the left hypochondrium. I considered her to be suffering from cancer. My colleague, Dr. Bushby, had under his care a sailor who had suffered from dysentery, and was admitted with a large swelling in the liver, high fever, and a leucocytosis of 22,000. Abscess was rightly suspected, but an exploration revealed a gumma, and appropriate treatment was quite successful.

I show a microscopical section from the liver of a young man, *æt.* 19; it shows a marked form of cirrhosis, but largely intracellular fibrosis and infiltration with round cells—a multicellular cirrhosis: it reminds one of the condition seen in congenital syphilis (figs. 1 and 2). If this is a true syphilitic cirrhosis, it is rarely seen in adults. Of my 5 cases of certain syphilis, the remaining 4 were of the gummatous type. Two I have mentioned, two recovered under treatment and had associated lesions.

This young man was admitted for abdominal pain. There was a history of hæmatemesis. Examination showed a large liver and spleen, ascites, but no jaundice. He said he had had no previous illness, and denied syphilis; nor were there any associated lesions. He died in a comatose state, with low, muttering delirium. The patient was very young for acquired syphilis, and congenital syphilis of the liver terminates at an earlier period in recovery or death.

In general, in addition to a history of alcoholic excess and dyspepsia on the one hand, or syphilis on the other, suggestive points in favour of the diagnosis of specific trouble are the fairly healthy appearance of the patients, the absence of wasting and toxæmia, of hæmorrhage or jaundice, or a large spleen.

But the case of the patient under the care of Dr. Bushby which I have just related, as well as that of the old lady, make one realise how cautious one must be in excluding this disease, and how wise it is to give the iodide and mercury. You may remember that Dr. Sydney Coupland's case of primary splenomegaly, one

FIG. 1.—C., *æt.* 19 (low power). Showing marked round-celled infiltration.

rare cases the combination of jaundice and ascites with a large liver is sometimes met with, and then

(a) Paper read at the Liverpool Medical Institution.

of the earliest of that class, and a case which attracted much attention and was shown at one of the London Societies, was found to have, on the post-mortem examination, a syphilitic liver, whatever might have been the nature of the splenic lesion.

Coming now to uncomplicated cirrhosis, there is no doubt of this lesion when it is seen in the dead-house, and sections are examined by the microscope. A host of authorities—Murchison, Niemeyer, Fagge, and more recently Hale White—maintain that it has a correspondingly definite and characteristic clinical history. Before considering what the course of this disease is, one must first recollect that though alcohol is a certain ætiological factor, yet the typical disease, both pathologically and clinically, may have an origin distinct from this cause of syphilis, as was the case in a patient—a young woman, æt. 22—in which no definite cause could be assigned (Fig. 3).

In this connection I may mention another example. A young man, 6 feet tall and very powerfully built; seven years ago he had an attack of scarlatina, and his people said that since then he had ailed somewhat with indigestion, but had otherwise been in good health. Alcohol and syphilis could be excluded. He was admitted with hæmatemesis, which terminated fatally in three days. This is one of the rare cases of fatal hæmatemesis which I have seen. The post-mortem showed markedly dilated œsophageal veins, and a liver in varying stages of cirrhosis. It may occur at any age, as was so in a boy, æt. 7, who had been given considerable quantities of alcohol.

It is impossible to say when cirrhosis will begin to produce symptoms: typical hobnail lesions are found in the post-mortem room in those dying from other diseases.

Many tests have been proposed to gauge the hepatic adequacy—notably the production of alimentary glycosuria or lævulosuria, the diminution of the urea in the urine, and the increase in the ammonia consequent on the formation of acid bodies. Kretz has especially urged the importance of these tests; but Bunge, in an exhaustive monograph, shows that many errors arise, and that there are many gaps to be filled, as in the kindred subject of the estimation of the renal adequacy, before one can presume too much on physiological teaching. Moreover, Jakoby, in the recent exhaustive *Ergebnisse der Physiologie*, says: "Anyone who realises how little we at present know

fection of methods." But, leaving this somewhat depressing utterance, I pass to the older and surer ground of clinical observation.

In Table I. you will find the history of a number of such cases.

You notice how rapid is the end when once symptoms have appeared, for how short a time they survive the ascites, and how many die of toxæmia with delirium and coma.

This illustrates very well the opinion especially of the Guy's school of pathologists—Fagge, Moxon, and Hale White.

The last named sums up: "The supervention of ascites in uncomplicated cirrhosis of the liver means that the end is near"; and again: "Cirrhosis of the liver is often latent, but its chief danger consists in the fact that patients suffering from it are liable to the more or less sudden supervention of symptoms which rapidly increase in severity and usually end in death. The chief are a general feeling of drowsiness, ascites, swelling of the feet, and toxæmia."

If this be the natural history of cirrhosis, there does not seem much scope for an operation which aims entirely at the relief of ascites by further assisting the collateral anastomoses between the portal and systematic circulation.

You will notice, too, that in my table of cases laparotomy was followed in some instances within a few hours by terminal symptoms of a nervous toxæmia, and in reading over the records of the 274 cases collected in Bunge's monograph this same fact of a rapid exitus is repeatedly mentioned. I cannot think this is without significance. In tuberculous peritonitis the cure of the ascites is, according to Wright, brought about after laparotomy, by renewal of the opsonic content of the blood to the peritoneal cavity; but in cirrhosis it rather appears that a disturbance of the balance of the circulation seems in some mysterious manner to reduce the already greatly impaired hepatic adequacy and precipitate the latent toxæmia.

The operation is further recommended as a prophylactic measure against hæmorrhage. Curschmann says he has seen fatal hæmorrhage from the dilated œsophageal veins in 12 cases, and it sometimes happens that small repeated hæmorrhages may cause a state of grave anæmia. I imagine this occurrence is not common. Preble has analysed, however, 60 cases of fatal gastro-intestinal hæmorrhage, and finds that, though not rare, it is infrequent. Clinical experience shows that these larger hæmorrhages occur in the early stages of the disease, often as an isolated symptom.

Is it desirable to interfere surgically for prophylactic purposes?

I am rather inclined to think at this period that the same result is likely to be obtained by rigid abstinence from alcohol, relief of the liver by diminution of the proteid intake, and general treatment. It is not easy, from a study of recorded cases, to find proof that a collateral circulation can be formed in such a way as not to put undue strain upon any of the relieving veins. Death from hæmorrhage has still occurred after this operation. If the operation of omentoplexy is performed for this purpose, viz., the prevention of hæmorrhage, the two indications according to Bunge are:—

1. That the disease must be in an early stage.
2. That there must already be evidence from the appearance of the veins over the skin of the abdomen that this spontaneous formation of a collateral circulation is taking place.

In the rare cases in which these two facts can be ascertained and the patient is becoming seriously anæmic from small hæmorrhages, the operation might be considered. It must, however, be borne in mind that though cirrhosis of the liver is a primary local disease, its effects are very general, and I doubt whether local surgery is likely to have better results than the similar attempts which have been made to cope with granular kidney (a somewhat comparable disease) by stripping away the capsule.

Leaving, now, uncomplicated cirrhosis, we come to a variety of pathological conditions characterised by

FIG. 3.—F. M., girl, æt. 22, cause not ascertained. Marked cirrhosis.

as to the physiological conditions of urea formation will not expect to gain much diagnostic information from observations on the sick, let alone the imper-

ascites, for the permanent removal of which omentoplexy, etc., have been recommended. These are:—

(1) Chronic perihepatitis and peritonitis, including the sugar-ice liver, but without cirrhosis of the liver.

(2) Chronic peritonitis combined with cirrhosis: this is nearly always a partial perihepatitis and peritonitis.

(3) The cardiac cirrhoses, including the pseudo-pericarditic cirrhosis, and the liver of mediastino-pericarditis.

Simple chronic universal perihepatitis and peritonitis are now known chiefly from the writings of Hale White. The liver is covered with a universal tough white jacket which can be easily peeled off. On cutting into this the liver substance bulges out, and microscopically is found to be healthy; the peritoneum is always similarly affected, the intestines matted together, and the omentum matted up like a thick apron. The spleen capsule is similarly invaded. With regard to its cause, Hale White says:—"It is almost universally associated with granular kidney, and frequently with gout, syphilis and over-indulgence in alcohol, and diseases of the heart and lungs causing backward pressure."

It is probably a less frequent condition than true cirrhosis. In the Manchester post-mortems there were 45 cases of uncomplicated cirrhosis to 8 of simple chronic peritonitis. Dr. Thomas Harris, in his well-known paper on mediastino-pericarditis, discusses this condition and finds that cardiac disease is a more constant associated lesion than granular kidney. Of the 5 cases in which I have diagnosed this lesion, the 2 which came to the post-mortem room had heart disease, and no true renal sclerosis, though, as Hale White says, both may exist, and it may be difficult to say which is the primary lesion (Fig. 4).

In some cases it is part of a general chronic inflammation of the serous membranes, a polyserositis or polyorrormentitis.

The important diagnostic clinical points are:—

(1) The absence of the jaundice, and toxæmic symptoms of hepatic inadequacy.

(2) Recurrent ascites and fair general health, but again the distinction from syphilis may only be made after a vigorous therapeutic test.

These are the cases in which the ascites is withdrawn so many times. In the Manchester figures the average length of life after the first appearance of ascites was over two years.

The cause of the ascites is certainly the peritonitis, and not any obstruction to the portal circulation—at least, dilatation of the portal vein has not been found.

FIG. 4.—H. (low power). Typical nutmeg liver, but marked perihepatitis, in a case of heart disease. There was ascites, but no general dropsy.

An attempt to form a collateral circulation does not, therefore, appear indicated, and unless the Morison operation is regarded as an attempt to obliterate the peritoneal cavity, its usefulness seems to me doubtful. In one of the patients of the Manchester series, although the operation was done, paracentesis had yet to be performed 70 times. The second group in which a chronic peritonitis exists with true cirrhosis is said by Rolleston to be rare. Yet, of 131 cases of simple chronic peritonitis, found cirrhosis in 10.7 per cent.; Sears and Lord in 19 per cent. In Hale White's series of 34 cases there was cirrhosis and general peritonitis in 6. In the Manchester series, 12 cases out of 68; and the average number of days survived after the first appearance of the ascites was 360. The tables give the findings in 124 post-mortem records, and from the clinical history it is certainly true that the prognostic gravity of the ascites is proportional to the amount of the cirrhosis and inversely proportional to the extent of the chronic peritonitis. This fact Ramsbottom expresses diagrammatically:—

C . . . . . A and T . . . death.  
C-P . . . . . A . . T . . . death.  
P . . . . . A . . . . . death.  
C = cirrhosis, P = peritonitis, A = time of appearance of ascites, T = time of appearance of the toxæmic symptoms.

Now since we cannot regard the appearance of chronic peritonitis as itself desirable, we are driven to conclude that when, with cirrhosis of the liver, this peritonitis does appear, such a cirrhosis has a different pathological value from the uncomplicated form where the appearance of the ascites is the herald of death. Here the toxic symptoms of hepatic insufficiency stand out, and the ascites itself is toxæmic. Could we diminish the rate of onset of hepatic insufficiency, then in time a chronic peritonitis might occur, and the associated ascites be of less grave prognostic significance.

The toxæmia occurs because the liver is unable to adequately deal in some subtle manner with the portal blood. The Morison's operation, if successful, supports the natural vascular anastomoses, and still further diverts the portal blood from the liver, i.e., it tends to cause a physiological isolation of the liver.

Yet it must be better to have a diseased liver than none at all.

In the Eck fistula, where the portal blood is diverted directly to the inferior vena cava, symptoms follow very like the toxæmia of cirrhosis in man. It is, however, known that regeneration of the liver cells may take place, and thus recovery of the hepatic functions may occur if the noxious causal agent (e.g., alcohol) is removed; further, in Morison's operation, Rolleston has suggested that the fresh blood-supply brought in this way to the liver may assist in regeneration of the cells.

Thus, on general pathological grounds, the indications for the operation in uncomplicated cirrhosis seem to me to be very limited. In the ascites stage they should be useless; and if, in the pre-ascitic stage, syphilis can be excluded and the alcoholic or other injurious habits arrested, would the ascites appear?

In chronic simple peritonitis the condition of the heart, vascular system, and kidneys must be scrutinised, and if these permit, then it may be justifiable to produce peritoneal adhesions with the object of obliteration of the peritoneal cavity.

In the mixed form, possibly there may in some cases be a balance of argument in favour of the operation.

### SOME NOTES ON ARTERIO-SCLEROSIS AND ALLIED CONDITIONS.

By SIDNEY H. HALL, M.B., C.M.,

Medical Officer Fusehill and Harraby Hall Workhouse, Carlisle.

CAUSATION.—The pathological remains of arterio-sclerosis are well enough known, the thickening of the intima tunica (with probably some change in the media tunica also) and the

narrowing of the lumen of the vessel have been familiar to all since student days. But the precise mode of origin of this condition cannot be said to be properly understood at present. Systematic overstrain, faulty habits of eating and drinking, and certain poisons such as lead, syphilis and toxins elaborated from, or imperfectly removed by, disorganised kidneys probably sum up our knowledge of precise causation. The occurrence of the disease in Russian Jews, who are said to present, in the majority of instances, evidence of early syphilis has been commented upon by many observers. There is, in my experience, a vague history of "muscular rheumatism" almost always to be obtained in such cases, a warning held out by Nature that unless habits are amended, a more severe toll will be exacted later. The disease is one essentially of inflammatory origin, and the smaller arteries, metacarpal, dorsal, metatarsal, are attacked by preference.

**SYMPTOMS.**—The symptoms are fairly definite, the patient not infrequently comes complaining of sudden darting pains, producing a feeling of cramp and numbness. The pulse is often sledge-hammer type, hard and infrequent; the second aortic sound is accentuated. The sphygmogram demonstrates details that the trained finger can almost follow step by step, a short up-stroke, broad crest and gradual down-stroke with a slight dicrotic wave. The left ventricle hypertrophies and general dilatation usually supervenes. If we add renal disease, which is practically always present in advanced cases, the clinical picture is complete and diagnosis should be a matter of ease. I have been struck also with the not infrequent accompaniment of acne, psoriasis, and chronic eczema in this condition. Further most detailed investigation as to the condition of the blood is necessary to a full understanding of this condition.

The subjects of it in the early stages are not easily detected, but it is strongly suspected by the writer that these are much more numerous than is commonly supposed. Many quite young people (contrary to the usually accepted idea) are sufferers from this condition, but are told that they have lumbago, muscular rheumatism, or some allied complaint. It is idle to suppose, as text-books would lead one to, that arterio-sclerosis is a disease seldom, if ever, seen till after the age of 50; there are many people under 30 who are true subjects of it.

**TREATMENT.**—The sheet-anchor of the practitioner in this disease is unquestionably iodides. What their precise therapeutical effect is I do not profess to know any better than others. The time-honoured term "alterative" must be sufficient, though alterative of what we are still ignorant. Suffice it that it is alterative for the better of the condition to which it is applied. There is no doubt whatever of the universal applicability of iodides to this ailment, but there are iodides and iodides, and a rigid adherence to the limited British Pharmacopœia is distinctly inadvisable. There is a notion abroad that if a practitioner finds something outside the hallowed precincts of the British Pharmacopœia which is really useful in practical medicine he must only mention it with bated breath.

Surely this is cramping therapeutic advance mostly unfairly, and one is rejoiced to see that many physicians whose motives are of the purest have boldly discarded this flimsy rule of etiquette and unhesitatingly advanced their opinions on so-called proprietary articles. I say so-called advisedly, for in my knowledge of them, their formulæ and precise chemical composition are for the most part freely declared, and it is therefore open to anyone to

compound the same article. The compound from which I have personally derived most practical benefit, in the treatment of arterio-sclerosis and a number of other ailments for which I at one time relied entirely on potassium iodide, is termed eustenine, and it is stated to be a blend of theobromin with sodium iodide—about 51 per cent. of the former and 43 per cent. of the latter. What the remaining 6 per cent. is I cannot say, but it would undoubtedly be ascertainable from the makers.

The action of this remedy is naturally the result of action of its component parts—iodine and theobromin.

As regards the action of the iodides in arterio-sclerosis there are two views, both of which are tenable and which, in point of fact, may both be taking place at the same time. The first is that the iodides exert an influence on the pathological change which has taken place in the intima, i.e., that they reduce the amount of sclerotic tissue. This is denied by some but is supported by the well-known property of iodine compounds in producing "absorption," as it is termed, a property which can be explained on no pharmacological basis. The second theory is one which has been advanced by German observers, and is to the effect that iodides render the blood less viscous or more fluid, and this results in a better circulation. There is a third, and, to my mind, a more universally applicable explanation, which is that iodides exert an effect on ultimate nutrition and on the work of the excretory organs. This effect on nutrition may be direct or indirect, but it is evidenced by the frequent alteration in weight which is usually noticeable under iodine treatment. This alteration in weight may sometimes be a gain, as, for example in syphilis. The well-known effect on glandular organs, the diuretic effect, the catarrhal state, and so on, induced by iodides are all evidences of powerful action on secretion and excretion. The action on secretion and excretion is bound, of course, to affect the composition of the blood, and it is this amendment of blood composition which results in amendment of the walls of the sclerosed vessels. Some irritant causing sclerosis is removed by the action of the iodide on the secretory and excretory organs, and the rest of the iodide may be used up in an alterative action on the already sclerosed condition. This at least supplies a rational basis for the use of iodides in this condition, and until more exact statements on blood changes are forthcoming nothing more definite can be said.

As regards the action of the theobromin contained in eustenine, I think its principal utility is that of indirect stimulation of cardiac action; blood pressure is lowered and there is an increased volume of blood brought to the kidneys for filtration and the elimination of undesirable products. The diuretic action is also indirect, but is none the less valuable. The drug is of particular value where there is a feeble but regular cardiac action. The blend of the two things produces a marked relief, particularly in acute arterio-sclerotic conditions.

I have found the remedy most useful on these grounds in many other conditions, some concurrent with arterio-sclerosis, such as angina, myo-carditis, asthma and emphysema, as well as for conditions which were apparently independent of vascular changes, such as pleural thickening, long-standing bronchial catarrhs, and certain manifestations of gout and rheumatisms.

The recitation of a few cases will serve to emphasise some of the points to which a general allusion only has been made.

1. Male, æt. 36. This patient was a Pole, who has spent some eighteen years in Nijni Novgorod, and had only been in England about four years, employed as a warehouseman. No history of syphilis. Illness commenced about two years ago with indefinite lancinating pains over right scapula which often passed down the arm and caused a feeling of cramp and numbness, which went off in a short time. For this he treated himself with aspirin, sometimes with benefit sometimes not. This pain had become more troublesome of late, and his right hand frequently became swollen and painful after much use. His knuckles felt tender and hot, and he ascribed the condition to the onset of gout, which he said was in the family. On the occasion of his visit to me the right hand was swollen, of a purplish red colour, and he said it always felt colder than the left hand. Pressure on the joints caused some little pain. Pains were stated to be frequently felt at various points all up the arm, but none could be elicited at the time of examination. The radial artery was distinctly thickened, and the pulse was moderately hard and infrequent. The urine was normal, as were the heart sounds. Temporal artery was distinctly tortuous. Patient confessed to being a large meat-eater and to being fond of spirits. He was given eustenine at the rate of  $7\frac{1}{2}$  grains thrice daily for a week, increased to 10 grains for a fortnight afterwards. At the end of five days the œdema of the hand had disappeared, but patient still felt a little stiffness in the wrist and fingers. At the end of another five days the hand was quite normal, and patient expressed pleasure at being able to clench his fist tightly with the greatest ease. He stated that he did not now "fumble" with the many packages which it was his duty to handle daily. The urine had increased in quantity and the hardness of the pulse quite disappeared. He has seen me several times during the past year, but has only once had to be put back on to this drug for a couple of days.

2. Female, æt. 38. Boarding-house keeper. For over two years has suffered from spasmodic attacks of pain in the right forearm and fingers with tingling numbness and coldness of the fingers. She complained that she frequently dropped things, owing to this feeling of numbness. She had suffered from an attack of rheumatic fever, but said it had left no ill effects. Her hair was quite grey, and there was already a commencing arcus senilis, whilst the temporal artery was distinctly tortuous. The external evidences of age were so pronounced that I was amazed when she gave her age as only 38. On examination her hands and arms showed slight psoriasis, the nails were transversely ribbed, and were said to be very brittle, often breaking off at the ends. She experienced pain in the right arm, particularly after carrying heavy weights or doing some unwonted movement such as hanging out clothes on a line. There was hardly any pulse perceptible at the right wrist, but an examination of the brachial and axillary arteries showed that pulsation in them was normal. The radial artery was obviously thickened, as was the temporal. First aortic sound reduplicated and dilatation of heart fairly marked. She was put on a mixture—potassium bi-carbonate, potassium nitrate, and sodium nitrate for about a week, but returned little better for the treatment. Eustenine was tried in doses of 10 grains thrice daily, but no improvement resulted for over a fortnight; perseverance, however, and an increase of the dose to  $12\frac{1}{2}$  grains thrice daily resulted in a disappearance of every symptom, except the cardiac dilatation, at the end of less than five weeks the dose of eustenine was then dropped to  $7\frac{1}{2}$  grains

again, and a little strophanthus and nux vomica given concurrently for ten days. At the end of this time the cure was, so far as is possible in this condition, perfect, even to disappearance of the aortic reduplication and signs of dilatation. There was a general feeling of well being such as had not been experienced for some time, it was said.

3. Male, æt. 46. This patient had quite suddenly, and without any apparent reason, developed acute pain behind the right internal malleolus. He put it down to a strain in walking, as it developed on his rising from a chair on which he had been resting after a brisk walk. However, it left only a little tenderness, and he rubbed it briskly with some camphorated oil. Next morning the same acute pain was experienced on getting out of bed, and was so bad that he fell on to the floor, and could not rise for ten minutes or so. Bathing with hot water relieved it, and he rested for some days at home. Whilst so resting, the pain again came on with the slightest of movements, and I was called in by his wife, who was getting uneasy. On examining him, I had occasion to flex and extend the ankle-joint, the pain again came on, lasting for three or four minutes, and being so acute as to cause profuse perspiration and collapse. Questioned as regards other pains of a similar character, the patient stated that he sometimes felt an acute stabbing pain down the front of the thigh and in the calf of the leg. There were no nervous signs, knee-jerks and plantar reflexes were normal, and there was no clonus. My first treatment was a smart blister over the seat of the pain, with small doses of potassium bromide. At first this gave relief, and for a few weeks I heard nothing more of the patient. The diagnosis was not clear to me, at the end of this time I was, however, again called in, the attacks having commenced afresh, they were now coming on about every ten minutes, during periods extending over three or four hours, and were leaving the patient in a more or less collapsed condition, and unable to put his foot to the ground. The patient firmly believed the condition to be gout, and stated that he usually experienced attacks of asthma about the same time, and also suffered from palpitation of the heart. A more detailed examination revealed the fact that the posterior tibial artery of the right side was somewhat thickened, and apparently more tortuous than the one on the left side. There was ventricular hypertrophy and marked accentuation of the second aortic sound; radial and temporal arteries thickened and serpentine; albuminuria also was present. Rest in bed was insisted upon, diet was carefully regulated, and eustenine in 10-grain doses commenced thrice daily. In a few days general improvement was obvious, the urine was clearing, attacks of pain were less frequent and less acute, and palpitation had quite disappeared. The dose of eustenine was increased to  $12\frac{1}{2}$  grains. At the end of a further fortnight, patient was able to sit up and exercise his foot freely without any pain supervening. There had been no attack of asthma since commencement of treatment, and the urine was perfectly clear. At the end of another week patient was able to resume work.

4. Male, æt. 54. Merchant living a half-retired life. Has been troubled lately with attacks of bronchial asthma, accompanied by a severe and persistent dry barking cough rendering rest an impossibility, and provoking great exhaustion. Evidences of the strain of life were distinctly marked, hardly an organ of the body performing its functions normally. Physical examination revealed a condition of bronchial asthma with emphysema and dilatation of the heart. Diet and mode of life made the subject of radical alteration.

In addition, iodide of potassium was prescribed, but had to be stopped because of gastric disturbances. Eustenin was prescribed in its place, 7½ grains thrice daily; taken well, and without producing any gastric derangement.

The asthmatic attacks gradually yielded to this remedy, becoming less violent and exhausting, and fewer in number. The bronchial catarrh entirely disappeared after three weeks of treatment, and a lancinating pain on the left side (query commencing angina) has not once been experienced since treatment was commenced. Urine materially improved, appetite returned, and general vigour and well-being now experienced. The patient still takes eustenin 7½ grains daily.

5. Male, æt. 29. Joiner, had suffered from two attacks of rheumatic fever and one rather severe attack of enteric fever. Came complaining of numbness and tingling in right hand and occasional sharp pains in shoulder and down back of thigh, which he ascribed to rheumatism. These pains came on suddenly, and incapacitated him from work. He smoked cigarettes at the rate of 25 to 30 per day, but was otherwise temperate in his habits. No history of syphilis. Pulse on right side so feeble as to cause me to examine carefully for aneurysm. His hands and feet were, he stated, persistently cold. The radial arteries were both distinctly hardened and tortuous, the right one mostly so. Temporal arteries both serpentine, hair almost gone, nutrition very poor. Potassium iodide produced effects on the skin and on the stomach which caused him to complain of the medicine at the end of three days. Eustenin 7½ grains thrice daily was substituted, and at the end of a fortnight there were obvious signs of improvement. The drug was continued for a further fortnight, and during the whole time of its administration no attacks of pain were experienced. Appetite and capacity for work were increased, and weight had gone up 5 lbs. in the month.

Coupled with the administration of any drug, one must have diet and hygiene of life carefully regulated, virtually on the lines prescribed for those of gouty tendency. With a return to a strict adherence to rational hygiene, the use of drugs will not be requisite except on rare occasions. The use of Kissingen salts, massage, plenty of rest, abstinence from alcohol and tobacco and the avoidance of fatigue are all-important factors in treatment.

So far as drugs are concerned, my faith in the combined iodine and theobromine treatment as afforded by eustenin of all conditions included under or accompanied by arterio-sclerosis is now practically immovable, and I commend the method cordially to those who have not already tried it.

## OPERATING THEATRES.

### ST. MARK'S HOSPITAL.

CARCINOMA OF THE DESCENDING LOOP OF THE PELVIC COLON (FORMERLY CALLED THE FIRST PART OF THE RECTUM). ABDOMINO-PERINEAL EXCISION (WITHOUT COLOSTOMY).—Mr. C. GORDON WATSON operated on a woman, æt. 54, a domestic servant. He said he was anxious to render her fit to continue her domestic duties, as she was an old and valued family servant. Until six months ago she was in good health. For the past six months she has been troubled with wind and intermittent diarrhoea, and has lost weight. These have been her only symptoms, and in all other respects her health has been good. Abdominal and rectal examination revealed neither tumour nor tenderness, but the sigmoidoscope demonstrated an obvious tumour 13 centimetres from the anus. The instrument was passed without the aid of an anæsthetic, which, he

pointed out, is never necessary. She has been kept in bed for nine days and carefully dieted. Several carious stumps have been removed. The colon has been thoroughly emptied, and she had a quarter of a grain of morphia half-an-hour before coming to the theatre. Both the abdomen and the perinæum have been carefully prepared. All these, he said, are important points in preparation for a severe operation. The anæsthetic administered was chloroform. The patient was placed in the high Trendelenberg position. A long median incision below the umbilicus was made. Mr. Watson then widely separated the sides of the wound with a self-retaining retractor, packed off the small intestines with gauze, and confirmed the sigmoidoscopic diagnosis by demonstrating a small constricting growth in the lower part of the pelvic colon. This was freely movable, but could not be brought outside the abdomen, otherwise it might have been resected. In many respects this would have been the ideal operation, because there was no distension above the growth, which was quite small, and because there was neither obvious glandular involvement nor adhesions. In other words, the case was an early one and not acute. The mesentery of the pelvic colon was long, long enough to reach to the anus. Mr. Watson decided to separate the rectum and lower half of the pelvic colon, together with its mesentery and the cellular and lymphatic tissues in the hollow of the sacrum (working within the abdomen), and then deliver them through the anus, working from the perinæum. The first part of this operation was then carried out without difficulty and without ligaturing the trunk or main branches of the superior hæmorrhoidal artery. The hollow of the sacrum was cleared by gentle separation with the fingers after division of the parietal pelvic peritoneum on either side of the bowel. The position of the ureters was kept in mind, especially the left. They were not disturbed. A group of vessels (middle hæmorrhoidal) was tied off on either side of the fixed portion of the bowel, with the aid of an aneurysm needle, and no other ligatures were required. The peritoneum of Douglas's pouch was then divided at its reflection on to the upper part of the vagina and uterus. It was then seen that the bowel could be easily pushed down so as to be subsequently delivered through the anus. A little hot saline was poured into the peritoneal cavity, and the abdomen rapidly closed. This stage was completed in half-an-hour. For the second stage the patient was placed in the lithotomy position. After dilatation of the sphincter four clips were attached to the muco-cutaneous junction: equidistant from one another, and the anus thus held open by two assistants. Whitehead's operation (as for hæmorrhoids) was then commenced, and when the mucous membrane had been freed from the sphincters as far as the upper limit of the internal sphincters, the muscular coats of the bowel were cut through, and the rectum peeled off the vagina until it could be freely drawn through the anus. After the bowel had been freed in this way, anteriorly and laterally, some difficulty was encountered posteriorly, probably from the mesentery at the upper part of the sacrum. No force could be used with safety, but eventually the resisting bands were tied off with the help of an aneurysm needle. This proved the only difficulty in the operation, and once overcome the bowel was freely delivered until over a foot of intestine hung outside the anus. A few stitches were then passed through the bowel wall, lightly suturing it to the anal margin, five inches above the level of the growth. The remaining portion (about 12 inches) was cut off with the actual cautery to save time in ligaturing vessels. A small incision was made between the coccyx and posterior anal margin, and a drainage tube passed up to the hollow of the sacrum, a strip of gauze passed up on either side of the gut between bowel and sphincter, and the operation completed by passing a tube into the new anus and lightly packing round it.

Mr. Watson remarked that resection might have been possible by working within the abdomen, but two grave risks would have been run, as the growth could not be delivered outside the wound and packed off:

(a) primary soiling of the peritoneum; (b) secondary soiling from subsequent leakage.

A more radical operation by Miles' method could have been done, but this would have involved a permanent colotomy, which he was particularly anxious to avoid for the patient's sake. It was not considered necessary, for the following reasons:—(1) The length of the mesentery, the small size of the growth, and the absence of adhesions rendered the operation adopted possible. (2) The distance of the growth from the anus made it possible to leave the sphincters and skin round the anus intact, without risk of recurrence in these situations. (3) The operation adopted enabled all the lymphatics in the hollow of the sacrum to be removed. (4) Although part of the pelvic mesentery was left intact, containing possibly infected lymphatic vessels, the early stage of the growth seemed to justify this risk, as a risk counterbalanced by the avoidance of colotomy. He said that the special points aimed at in the operation as performed were:—(1) To excise the growth together with the lymphatic vessels and glands in its immediate neighbourhood. (2) To leave the sphincters intact, and to provide an anus in the normal situation. He pointed out that some of the advantages of a combined method of excision were:—(1) To confirm diagnosis and to obtain a clear view of the actual condition of affairs. (2) To enable the surgeon to see exactly what he was doing in carrying out a radical operation. Some of the disadvantages of a sacral method were:—

(1) A radical operation is seldom, if ever, possible, and always more difficult. (2) The exact state of affairs cannot be seen. (3) The growth may prove to be more extensive than expected, and this may not be ascertained until the operation is so far advanced as to necessitate completion (of an incomplete operation).

The dangers to avoid in the combined operation as performed:—

(1) Cutting off the blood supply of any portion of the bowel left behind, either by ligature or excessive tension on the mesentery.

(2) Damage to ureters and vagina (or urethra in male).

(3) Hæmorrhage in the hollow of the sacrum.

## TRANSACTIONS OF SOCIETIES.

### EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD WEDNESDAY, NOVEMBER 3RD, 1909.

The President, Dr. JAMES RITCHIE, in the Chair.

A FAREWELL ADDRESS, which will be published in our next issue, was delivered by Dr. RITCHIE.

In proposing a vote of thanks to Dr. Ritchie for his address and his conduct in the chair, Dr. T. S. CLOUSTON said that, whatever views might be held as to Weissmann's theory of heredity, as practical men they could never afford to neglect the enormous influence on the germ plasm of its parental environment.

Dr. BYROM BRAMWELL, the newly-elected President, then took the chair.

Dr. BRUCE and Mr. WALLACE read a paper on FRACTURE, DISLOCATION OF THE AXIS VERTEBRÆ; REDUCTION, RECOVERY,

which will be published in full in our next issue.

In the discussion which followed, Mr. MCGILLIVRAY and Dr. BYROM BRAMWELL pointed out the difficulties which arose as to the exact cause of the condition. Their feeling was that it was difficult to see how mere muscular movements such as had been described could have broken off a normal odontoid, and it was suggested that some malformation, or some disease, rendering it especially weak, might have been present. Dr. Byrom Bramwell agreed that the case was most remarkable. A state of matters of this kind produced by disease might well be recovered from, but a sudden paralysis of the whole body due to injury was, he thought, almost invariably fatal. He supposed that in

this case the pressure must have been comparatively slight.

Dr. BRUCE said he thought there had been one case of fracture of the odontoid from a similarly trivial cause. The odontoid was united to the body of the axis by a layer of cartilage which persisted to some extent throughout life, and he thought that fracture occurred at this point. He believed that the skiagrams shown afforded complete evidence that the odontoid had actually been fractured on October 7th.

Mr. WALLACE said that the credit of urging that the dislocation should be reduced rested with Dr. Bruce, as he himself had been averse to run the risk.

Drs. TORRANCE THOMSON and DENIS COTTERILL read NOTES ON THE SCOPOLAMINE-MORPHINE COMBINATION AS AN ANÆSTHETIC AGENT.

Two different methods of using the drugs were tried:—(1) The administration two hours prior to operation of 1/64 gr. scopolamine with 1/6 gr. morphine sulphate. In the great majority of the 34 cases on which this method was employed, anæsthesia was induced by chloroform and continued by ether. (2) Three preliminary doses of scopolamine-morphine (1/120-1/100 gr. and 1/4 gr. respectively) were given, 2½ hours, 1½ hours, and ½ hour before the operation. The effects of the drugs given in these two different ways differ only in degree, being more pronounced when three preliminary doses are given. The advantage of scopolamine and morphine depends on the fact that the hypnotic and anæsthetic properties of the two drugs associate themselves, while their toxic effects on the respiration and circulation being antagonistic, counter-balance each other. The patient is prepared in the usual way, and the drugs injected subcutaneously into the arm. After so large a dose of scopolamine as 1/64 gr., the patient complains of giddiness, but with smaller doses this does not occur. In most cases the patient goes to sleep in from 10 to 15 minutes, and though he may waken when he is lifted from bed, he quickly falls asleep again. Chloroform can be administered without awakening the patient. Less anæsthetic than usual is required to get the patient sufficiently "under." What is desired is to produce a degree of narcosis deep enough to prevent active resentment when a skin incision is made. In an elderly patient who was regarded as ill-suited for general anæsthesia, a scirrhus of the breast was removed under scopolamine-morphine and local anæsthesia. She lay perfectly quiet while the breast was being dissected out, and when questioned the following day had no idea she had had her operation performed. When a patient awakens during an operation, a few whiffs of anæsthetic suffice to quieten him, which points to the movements being reflex rather than conscious. The method adopted by the writers was to put the patient fairly well under chloroform, and to remove the mask after the skin incision was made, and only to re-apply it on some indication of returning consciousness. Actions prone to disturb the patient are skin incisions, traction on the stomach, parietal peritoneum, or spermatic cord, or moving him about much. In certain stages of abdominal operations it is necessary to give more anæsthetic in order to relax the abdominal wall.

Too much stress should not be laid on the corneal reflex as a guide to the depth of anæsthesia. The pupil contracts as narcosis deepens; the breathing is slower than under ordinary narcosis; it may fall to 12 or less per minute, but is not laboured, and resembles that of ordinary sleep. The pulse is not materially affected. In a case of lobar pneumonia the anæsthetic was successfully administered for the purpose of allowing the uterus to be cleared out. The combination is particularly satisfactory on frail and elderly people. Sickness is conspicuous by its absence, and in the opinion of the Ward Sister the afternoons and evenings of operation days are much quieter than before the routine use of scopolamine-morphine.

The writers drew the following conclusions from their observations:—

1. That scopolamine-morphine does away with the sense of fear prior to operation, and diminishes emotional shock and strain.

2. That the amount of the general anæsthetic required is much diminished, though this, in the writer's opinion, was not one of the strongest points in favour of the method.

3. The mucous and salivary secretions are inhibited by the drugs, and the trouble these give is thus avoided.

4. There is less sickness after operation.

5. Patients sleep on for several hours after operation, and are thereby spared a great deal of suffering.

In concluding, the writers suggested that scopolamine-morphine might be used prior to the induction of spinal anæsthesia, to overcome the disadvantage of the patient remaining acutely conscious of what was going on.

#### ULSTER MEDICAL SOCIETY.

MEETING HELD IN THE MEDICAL INSTITUTE, BELFAST, ON THURSDAY, NOVEMBER 4TH, 1909.

The President, Mr. T. S. KIRK, and subsequently Dr. J. J. AUSTIN, in the Chair.

MR. KIRK, after thanking the members for their help and support during the year of office, introduced Dr. Austin as his successor.

On the motion of Dr. JOHN CAMPBELL, seconded by Dr. W. G. MACKENZIE, a hearty vote of thanks to Mr. Kirk was passed by acclamation.

Dr. AUSTIN then proceeded to deliver his Inaugural Address. He said that, after twenty years' membership of the Society, he could testify to the great benefits which its membership conferred upon the general practitioner, and he urged all, and specially the younger men, to take advantage of the meetings, and to take part in them, even if only by asking questions. As the subject of his address that evening he had chosen the question of

#### LIFE INSURANCE

as it affected the medical man, first as a participator in the benefits of life insurance, and secondly as a medical referee.

Most medical men passed through some lean years when they began practice, and as they were often married at an early period, with increasing responsibilities, the only way in which they could make provision for their families in case of their early death was by insurance. He urged the desirability of early insurance, but said that far more care ought to be given to the selection of an office than was generally the case. The choice would depend partly upon the age of the applicant, and partly on the benefits desired, for some offices offered better conditions to early insurers, and some to later. Some offices offered special facilities for loans for building purposes, and the conditions of payment of bonuses, etc., differed widely. The popularity of life insurance as an investment was shown by the fact that whereas twenty years ago the premiums paid in the year amounted to 17½ millions sterling, last year they amounted to no less than 40 millions.

In his remarks on the second part of his subject, Dr. Austin said that he addressed specially the general practitioner, for, with all due respect to the consultant and specialist, he thought that life insurance work, which was largely a question of prognosis, was best dealt with by the man who was accustomed to watch his patients from year to year, and see the effects of age and illness. The examination called for now is much more thorough than it used to be. It was best made in the quiet of the referee's own consulting room, where he had all his appliances at hand. The applicant's own medical man was as well not present, he thought, though he might be asked for a confidential report. It was necessary for the referee to grasp the general features of the case quickly and give a decided opinion.

*Personal Appearance* should be carefully noted, as it often gave valuable hints.

*Heredity* was undoubtedly important, though he was inclined to think that its importance had been exaggerated

in the past, specially as regards phthisis. If the applicant belonged to a family in which two cases of phthisis had occurred, it used to be customary to reject him, but now, if he had left home early, and had lived in a healthy environment for years, he was often accepted without demur.

*Personal History.*—It must never be forgotten that loss of weight was often one of the first symptoms of phthisis, and that an attack of pleurisy, apparently trivial, was often tubercular, and followed by phthisis.

*Mode of Life.*—The answers to questions about the mode of life were often misleading, and sometimes unintentionally so. He never had met a man who confessed to being a hard drinker. Such could always name someone else who drank twice as much as he did. The importance of temperance was conclusively proved by the statistics of the offices which had temperance and general sections. The latest statistics showed that in one such office the expected deaths in the temperance section were 457, and the actual 274, while in the general section the expected were 461, and the actual 407.

*Physical Examination.*—The capacity for expansion of the chest was more important than its actual size. He had often been surprised to note how few people except singers could take a full breath. As regards height and weight, there were certain well recognised relationships, and a departure of more than 15 or 20 per cent. from these should be looked upon with suspicion. Obesity was often a danger sign, and the girth at the umbilicus should not exceed that at the nipple line. As regards cardiac disease, while aortic regurgitation was a bar, many offices now accepted cases of mitral disease with some penalty, and, as he thought, rightly accepted them. It should be remembered that over-frequency of the pulse was often only due to nervousness, and intermittent pulse to digestive trouble, but an irregular pulse, with several slow beats and then several fast, was a serious matter. Suppuration in the ears must be carefully considered. If the perforation was healed and there had been no discharge for several years, the life might be accepted as an ordinary one. But if a perforation were still present it should only be taken as an extra risk, and if suppuration still persisted the case should be deferred.

The urine, of course, called for careful examination. It should always be passed in the presence of the referee. Note the specific gravity carefully. If this was low, and there were signs of increased arterial tension, the case should be deferred, even though no albumin was found. If albumin were found, its source must be carefully sought for. It was now recognised that there might be physiological albuminuria, especially in young people, depending on some condition of the blood, and not on renal disease. Such albumin might appear in the afternoon, but be absent in the morning. It was abolished by the administration of calcium lactate. In such cases a small additional premium should cover any additional risk. Albumin from renal disease was not abolished by calcium lactate, and was accompanied by casts, etc. Such cases should not be accepted. In cases where a small amount of sugar was present it was often hard to decide. He would examine several times, and if none were found after the first time he would accept. It was very risky to accept a case of persistent glycosuria.

*General Questions.*—Some general questions were asked, as a rule, one of which he did not think fair. The medical referee was asked to say what extra premium should be put on a case he considered doubtful. In his opinion this was a matter for the actuary and the principal medical examiner together. The referee should be asked if he considered the life average slightly, moderately, or greatly under the average, and, having done this, his duty should end.

On the motion of Sir JOHN BYERS, seconded by Dr. W. M. KILLEN, a hearty vote of thanks was passed to Dr. Austin.

A FRESH outbreak of beri beri has occurred at the whaling station, Inniskea, county Mayo. Seven persons are affected, and one has succumbed.

## CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS  
ABROAD.  
FRANCE.

Paris, Nov. 7th, 1909.

## RE-CALCIFICATION FOR CONSUMPTION.

ACCORDING to Dr. Ferrier, the author of a special treatment of phthisis by the administration of calcareous salts, the cause of the progressive development of tuberculosis is to be found in the insufficiency of lime salts in the organism. The malady itself possessing pre-eminent decalcifying effects, the rational treatment should be that of restoring to the system the minerals necessary to the organism.

This view would seem to be corroborated by certain authors, as Prof. Robin and Dr. Lecreux, who remarked that tuberculosis was particularly noticed in regions where the soil and the water were poor in calcareous salts.

Dr. Ferrier's treatment consists in suppressing all acid in the food which dissolves the minerals, and the administration of carbonate and bi-phosphate of lime:

Carbonate of lime, 10 gr.

Phosphate tribasic of lime, 4 gr.

Calcined magnesia, 1 gr.

At the same time, the patient takes a glass of mineral water (St. Galmier, Pougues, etc.) early in the morning, and half-an-hour before each repast.

All acids, we have said, are excluded from the food, entailing the suppression of wine, beer, cider, liqueurs, butter sauces, lemons, oranges, vinegar, old cheese, certain fish, such as mackerel, herring, salmon.

Bread should be taken in moderation, not more than 10 ounces a day; potatoes, carrots, split peas, eggs, lean meat, cooked fruit, and non-acid jams should form the staple food.

Dr. Ferrier was so convinced of the efficacy of this treatment that he opened a free dispensary in one of the populous quarters of Paris, where hundreds of patients are being treated, and it must be admitted with encouraging success. The patients, recruited mostly from the working class continue their work while following the treatment.

The effect of the treatment would be a more or less rapid improvement in the condition of the lungs, ending finally in sclerosis and emphysema, while the fever disappears after a few weeks, facts confirmed by independent witnesses.

This method, which has the advantage of simplicity, is worthy of imitation, especially with regard to the poorer classes in large towns.

## ZONA.

In every case of zona or shingles there are two morbid elements which should be taken into account for the treatment: the eruption and the pain.

As regards the former, the treatment differs according to the condition in which the vesicles are found. If they have not yet ulcerated, the parts may be covered with some drying powder, as starch associated with boric acid, oxide of zinc, bismuth, or camphor. The region will previously receive a slight coating of vaseline to fix the powder; cotton wool and a bandage terminate the operation. If the pain is severe, the eruption may be painted with a one per cent. solution of cocain or, according to the method of Prof. Chauffard, with a (c) solution of ether and picric acid (one-half per cent.), every third day.

If, on the other hand, the vesicles are ulcerated, the powder should be replaced by applications of glycerine and starch, or by caron oil.

Certain physical agents, and especially the continuous current, have been used with success against the eruption and the pain. Dr. Duclos employs high intensities, up to 45 milliamperes in daily *séances* of ten to fifteen minutes.

Against the neuralgia of zona, several drugs have been used, such as antipyrine, aspirine, salicylate of soda, opium pills, and belladonna, as the malady is essentially of arthritic origin. These agents have a favourable influence on the painful element of the affection. Such irritating applications as collodion, tincture of iodine, poultices, or wet compresses,

should never be prescribed, as they soften the epidermis, thereby facilitating its removal, which should be avoided.

## LOCAL ANÆSTHESIA.

A simple method of rendering hypodermic injections painless for timid patients, is practised by Dr. Salémi, of Nice.

After rubbing the part with a solution of alcohol and phenic acid, and then with ether, he lets fall from a height of two or three inches, drop by drop, ether from a drop bottle for one or two minutes, when the injection can be made without causing any pain.

This method is particularly useful for certain solutions which, in themselves, are painful, amongst which might be mentioned injections of benzoate and bi-iodide of mercury, cacodylates of guaiacol or iron and citrate of iron.

## WHY THE WORLD DRINKS.

From recent official statistics, France consumes the most wine, Italy, Spain, Portugal, Austria, Hungary, and Germany produce wine, but the country which produces that beverage, so much appreciated by our travelling unpledged abstainers(!) in by far the largest quantity, is France; its annual production amounts to one-third of the whole world.

France consumes yearly 163 litres (1 litre = 1½ pints) per head, Italy 84, Spain 83, Roumania 27, Hungary 20, Austria 17, Servia 15, Germany 7½, United States 1½, England 1½ litres.

Germany is the principal producer of beer, but the record of consumption belongs to Belgium with 225 litres, England 125, Germany 120, Denmark 73, United States 76, Austria 65, France 30, Russia 5, Italy 1!!

As regards alcohol, Denmark takes the lead with 6 litres 3 per individual, France 3, 54; United States 3, 30; Russia 2, 40; England 2, 35.

## GERMANY.

Berlin, Nov. 7th, 1909.

At the Naturforscherversammlung, Hr. A. Exner, Vienna, related three further cases of

## TUMOUR OF THE HYPOPHYSIS,

that had been operated on in Professor Hochenegg's wards. The patients were females in the early part of the thirties. In each of the cases the disease was one of so-called malignant adenoma of the hypophysis. Notwithstanding the fact that complete removal was an impossibility, there was no recurrence; the malignancy of these tumours was not very great. He considered hypersecretion, or perhaps changed secretion of the hypophysis to be the cause of acromegaly. The chemical features seemed to be similar to those accompanying gravidity and lactation. Disturbance of the secretion led to disturbance of the function of the germ glands. Hypersecretion of the hypophysis also appeared to be responsible for the adiposity. In two cases there was increase in the thyroid after the operation. Hr. V. Eiselsberg, Vienna, had operated in five cases of disease of the hypophysis. Four cases of the Fröhlich type (adiposity, hypogenitalism) were materially improved, in two complete recovery took place. Excessive visual disturbance disappeared, and the genital function that had been extinguished or in abeyance was restored.

The *Deutsche Med. Zeit.*, No. 84/09, has a communication on the subject of

## ANAPHYLAXIS,

from a report by Dr. Pfeiffer, of Gratz, who investigated the subject with Dr. J. Finsterer as collaborator.

Animals, the communication states, *i.e.*, guinea-pigs, that have undergone no previous treatment, or only by the injection of serum from the healthy human subject, do not react when expressed juice from a cancerous mass is injected either with anaphylactic general symptoms or with an anaphylactic fall of temperature.

On the other hand guinea-pigs that have received by injection into the peritoneal cavity serum from an individual suffering from cancer, and 48 hours later have an equal quantity of expressed juice from the tumour tissues injected, do show severe anaphylactic

symptoms, amongst them an exact measurable anaphylactic fall of temperature.

The serum of a cancerous individual therefore differs from that of non-cancerous persons, in that it contains a free anaphylactic antibody.

In all cases examined hitherto it can be shown that in the course of a carcinomatous affection the patient forms antibodies not only as regards his own tumour, but as regards carcinomatous tissues generally. This free specific antibody can be transmitted through the peritoneum of the guinea-pig, and it here sets up a passive anaphylaxis against tumour issues. This can be proved to be a passive anaphylaxis by making 48 hours later an injection of a sufficient quantity of expressed juice of cancer tissue, when the anaphylactic fall of temperature takes place. From the foregoing the following conclusions may be drawn:—

1. The quantity of anaphylactic bodies in the serum of patients suffering from cancer is, even in the early stages, constantly so high that the same condition of anaphylaxis may be transferred to guinea-pigs.

2. It is proved that these anaphylactic bodies are present in the serum of individuals suffering from malignant disease, and that they are not present in those who are not suffering from any malignant affection, and that the radical removal of a malignant tumour is followed by a decline in the anaphylactic symptoms.

The consequences of this are:—

(a) Purely diagnostic: the presence of the anaphylactic condition in a patient with a tumour proves that a diagnosis of "malignant tumour" is correct.

(b) Regarding indication: it is that an operation must be undertaken where practicable.

(c) Prognosis: If after the operation has been performed the anaphylactic condition disappears, and does so permanently, it is a sign that recovery from the malignant disease has been complete. On the other hand, if there is a return of the anaphylactic condition it is equally an indication that some malignancy still lurks in the patient's system.

The subject was again introduced by the writer at the Naturforscherversammlung, but nothing new was added to it.

## AUSTRIA.

Vienna, Nov. 7th, 1909.

### LUMBAR PUNCTURE IN PERTUSSIS.

DR. ECKERT, assistant to Prof. Hubner, has given us a long record of cases treated in the wards with brom. potassium 0.3 gramme four times daily, and an occasional clysm of 0.5 to 1 gramme of chloral hydrate, with a death-rate of 176 in 476 cases, or about 37 per cent. These figures are confined to children about two years of age. The post-mortems revealed no morbid centre in all the cases, no lesion was to be found, except oedema of the brain and membranes. From this condition it was reasonable to anticipate relief by aspirating the lower part of the cord. Bertolotti performed the operation with marked success on a severe case of a boy three years of age; spasms quite disappear after the second operation. Escherich records several cases of eclampsia he has cured by a similar process.

After these examples, Eckert commenced with four cases of whooping-cough with severe eclamptic contraction, adding a bath to the treatment immediately after the operation, in order to encourage absorption, after relieving the tension in the spinal cord and brain. All the four recovered as by magic. Others have been treated since when unconscious and brought into the wards as dead, the treatment being followed by a speedy recovery. He contends that the bath after the operation is an important adjunct, as it stimulates the respiration, increases the venous flow, and at once removes the oedema, the immediate cause of the disorder. Many lives in his hands have been saved when all therapy was hopeless.

### DIABETES.

Noorden, in one of his clinical lectures, impresses his pupils with the importance of early treatment by a systematic diet in glycosuria. It is hard, he tells

them, to get the "Diabetiker" to conform to a suitable diet, but where this can be done it has a powerful influence over the future of the patient.

He is very sceptical about treatment when the disease is well advanced, and thinks all the vaunted methods of successful treatment by others may be disappointing in his pupils' hands. Diabetes usually commences with transitory periods at first, and may be short at the beginning, but the cycles gradually increase till they are finally established as constant. This is true of both the harmless alimentary and neurogenic glycosuria—both are progressive in nature.

### STITCHING VESSELS.

Ranzi, at the Naturforscher meeting, drew attention to the sewing of vessels which he had practised after the Carellstich method. The last were two cases of the brachial artery; one where the arm was badly crushed and the vessels ruptured, the second from a fracture of the bone and destruction of the vessel. Eiselsberg has recorded two similarly successful cases. The most important part of the treatment is rest and avoiding compression. If gangrene should set in, the application of leeches should first be resorted to.

Schmieden, in the discussion, gave the history of several cases where the vessel had been resected and excellent results obtained; even sclerotic vessels in the mammae, as well as the brachialis, had been successfully treated. Two of the latter, however, ended fatally. After the operation of transplanting a part of a vein for an artery after Wieting's method, the pulse resumed the normal in the arm, but, unhappily, the heart gave way and the patient died after one-and-a-half days.

### REPOSITION AND RETENTION OF FRACTURED FEMUR.

Lorenz raised the old question of treating a fractured femur when broken at the neck. The usual extension method in bed was not satisfactory, as an unsightly deformity was the common result. Bardenheuer's method had not been practised by him, and he had therefore little knowledge of its merits. The head being so small, the surgeon has little power in its correction; however, the shaft should be corrected in relation to the head of the bone by first abducting, rotating inwards, at the same time slightly bending the limb, and then fixing with bandages. Where difficulties present themselves narcosis should be resorted to during reposition and fixation, and afterwards the limb retained in this position sufficiently long for union, but not too long to cause stiffening of the joint. Hacker preferred reposition under narcotics, then extension, and finally a gypsum bandage.

Danzig said the greater number of these cases suffer from coxa vara adolescentium, which weakens the structure. He has practised Bardenheuer's method, with the best results, more particularly with elderly people.

Köln said Bardenheuer's method was advantageous in keeping the fragments apart, and preventing absorption of the bone, which invariably occurred when they were allowed to press on each other. Bardenheuer prefers a weight of 30 kilos (60 lbs.) freely running on the adult.

## HUNGARY.

Budapest, Nov. 7th, 1909.

### THE TREATMENT OF GOUT.

GOUT was a relatively uncommon disease in Hungary one or two decades ago. However, in recent times it has become more and more frequent. Probably the reason lies in the improvement of the nutritive conditions of the people. The statistical data show that twice as much meat is consumed now as was consumed 15 years ago per head. The increase in wages in agriculture enables workmen to have meat once in a day at least, while formerly their only food was bread and bacon. On account of the low price of meat, there are better paid workmen who eat meat three times a day. This fact naturally cannot be left out of count in the consideration of the aetiological factors of gout. The cases are mostly of the lighter type. They are definitely not so severe as

cases reported by English authors. The reason of this fact can be found in the weather conditions. Hungary, fortunately, has very stable weather. Rain is proportionately scarce. The winter is not very cold. The spring is very mild, the summer hot and dry. There are not more than 60 rainy days in a year on an average. As for the treatment, we can boast that we are enabled by Nature to heal gout much easier than any other nation—namely, we have a natural resource of lithia waters, which, being in abundance, are sold at a very low price, so that the very poorest gout sufferer may drink them instead of ordinary water. The constant use of a well-selected water is very beneficial for gouty cases, because the pains quickly abate, and an abundant diuresis sets in, which greatly promotes the solution of uric acid deposits in the joints. It is an every-day experience that the daily quantity of the urine rises to 2½-3 litres without the administration of any drug, merely by drinking mineral waters. Our foremost uric acid solvent water is the "Sultan" water. It has been analysed by Dr. Weiser, Royal Chief Public Analyst, who declared that the great quantity of lithium that it contains places the "Sultan" water above comparison for the treatment of maladies of the kidneys and bladder. Its diuretic and uric acid solvent property is unique, and was recognised even by the authorities at a London exhibition, where it was awarded a gold medal for the stability of its composition. The water is very much used as a table water, too, being very pleasant and refreshing when taken with wine or alone. It has no disagreeable after-taste, it is pure, saturated with natural carbonic acid, and is absolutely sterile, and even when bottled is exempt from pathogenic bacteria. Not only is "Sultan" water one of the very first-class of curative waters, but its agreeable taste and its purity with regard to bacilli render it the best preventive against those diseases that are propagated by water. The vast bottling establishments erected by the management satisfy, moreover, the most exacting demands of hygiene.

Of course, there are cases where mineral water alone fails to check all the unpleasant symptoms connected with gout. In such cases colchicin stands in great favour with Hungarian doctors. When we remember that Hungary is possessed of really efficacious sulphuric thermal spring baths, like Pistyán (with 3,600 foreign guests last year), and Felix Bath, near Nagyvárad, then it will be seen that a gouty patient can consider himself lucky if by chance he lives in Hungary.

## LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

### VIAMI REMEDIES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Supplementary to the recent letter of "General Practitioner" on the Viavi treatment, in the MEDICAL PRESS AND CIRCULAR, I would call attention, as an example that should teach the public the folly of belief in advertisements, to the rise and fall in popularity of so-called medical vibrators.

More than a quarter of a century ago, the late Dr. Mortimer Granville, taking up an old idea, invented an instrument by means of which vibration could be used conveniently. The application gave the illusion of a mild Faradaic current, and the present writer was instrumental in presenting this "percutor," as it was termed, to the French Academy of Medicine, and wrote a short note in the *Progress Médical*, when Boudet de Paris devised a similar apparatus, claiming the priority for Dr. Granville.

Charcot and others afterwards used improved appliances of the kind for the treatment of nervous disease, and especially of neurasthenia, and a certain number of psychosthenics have no doubt been distracted and amused back to a more healthy condition in this way; but until a few years ago the treatment was applied by specialists only.

Then came the craze for physical culture, and an

intelligent charlatan, recognising the possibilities of the idea, devised and launched on the world the Voodoo vibrator.

Testimonials from members of Royal families, of the aristocracy, of the legislature, of the medical profession, and especially of the clergy, simply rained on the promoters, and the amount of money spent in advertising is sufficient proof of the profits that must have been made.

A chemist at Ramsgate told me recently that two years ago he sold daily three or four vibrators at 30s. each, whereas at the present time they are a drug on the market, and he would be willing to sell those remaining at less than a tenth of their original cost.

The public, which is always ready to be duped by every new quackery, has had then, as it always does in the long run, sense enough to discover the fallacy of this particular humbug, and vibro-therapeutics have been relegated for a time to their proper place in regular medicine, as an exceptional treatment for special cases.

The Voodoo is, however, still used occasionally by empirics, but these know that when a patient treats himself the efficacy of the instrument decreases as he penetrates its mystery and tires of it as a toy. To keep up interest it should be applied from time to time only, with discretion, and the augur should not reveal the simplicity of its mechanism. Such is the formal opinion of a practitioner in stello-therapy, whom I occasionally meet, more or less professionally, and who makes an excellent living out of this hitherto neglected art. Stello-therapy, it should be said, consists in the application of electricity by the hand of the operator to a patient immersed in water.

"This mode of treatment," says the "Professor," for such is my *confrère's* (are we not all brothers?) self-conferred title, "is so marvellous, so *épatant* even, that it almost attains to the supernatural, to the *au-delà*. It is for this reason that I call it stello-therapy, and a high-sounding name necessarily increases its *prestige*."

I will add that my colleague, whom I employed formerly as a masseur, although claiming to be able to cure any kind of pain, professes not to practice medicine. Notwithstanding this, he has done several terms of imprisonment for illegal practice, the last time for laming a boy. This, of course, has only enhanced his popularity.

It seems to me, Sir, that the education of the people concerning quackery might be helped by the publication of a book on the same lines as the articles in your columns by Dr. David Walsh, but the exposures made by Dr. Walsh might be supplemented by a demonstration of the fact that every "new discovery" is simply the re-edition of an exploded imposture, and that the same claims have always been made in the same words, always believed by the credulous for a time, and always discovered ultimately to be fraudulent.

Such knowledge might protect the public from two kinds of purchases:—(1) Medicines which are harmful because they really contain powerful, but dangerous drugs; (2) medicines which are simply swindles, because they contain nothing at all.

An American remedy of the latter class was exploited towards the middle of the last century, with such success that it seriously interfered with the business of other irregular practitioners, and an old man who had taken it, dying in the ordinary course of Nature, was said to have been poisoned by its use. The proprietor of the medicine was accused of manslaughter, and notwithstanding the testimonials of many grateful purchasers, things were going so badly for him, that in order to vindicate the innocuity of his nostrum, he was obliged to tell the truth, and proved irrefutably that it contained medicinally nothing at all!

A book of the kind suggested should show that plausibility is not proof, and that pseudo-scientific explanations are baits to be swallowed by the credulous and by those who wish to be deceived. Examples could be multiplied *ad infinitum*, but are superfluous here.

In a recent brochure, however, "*Un Voyage Chirurgical aux Etats Unis*," my friend, Professor Pozzi, has

given an instance of colossal impudence which is worth relating, and had he not given a facsimile of the text of the journal lending itself to this cruel swindle, it would seem almost incredible.

The advertisement in question consists of an illustrated article for which, says Professor Pozzi, \$250 is paid per insertion. The largest of the six cuts represents a sharp-pointed metallic cone, held by a hand which is slowly forcing it through the "pores" of the abdominal wall.

The article is entitled "New Bloodless Surgery: Remarkable new operation which prises open a hole without cutting the flesh, and enables the surgeon to reach and remove the appendix without pain or bloodshed." Fig. 1 shows "the curious new, smooth, round instrument called the 'Reidiseam,' which opens a hole in the tissues without shedding blood or causing any shock." Fig. 2 shows "how the instrument is inserted into the abdomen three inches to the left of the hip-bone, making a hole as large as a silver dollar through which the diseased appendix can be reached."

The third cut shows a large circular hole, held open by eight curved retractors, attached by straps to a circular ring. The legend says: "New expansion ring with which the hole (in the wall) is held open, whilst the surgeon extracts the appendix." At the bottom of the page is a photograph representing four nice-looking nurses watching the operator, whose hand is pressing on a sheet, a thoughtful-looking assistant (the pathologist, probably) in the background. "The patient is under the white sheets, and all preparations have been made for the operation."

The other illustrations are a photograph of a child standing at the top of some steps before an open door, with a glass jar in her hand. This represents "a little girl patient, with her appendix in her hand, leaving for home at Rome, N.Y., on the day of the operation"; and, lastly, to convince the most unbelieving, another photograph of a huge ligatured appendix. This, evidently the chief *pièce à conviction*, the chief proof of *bona fides*, is labelled, "Diseased appendix after removal; a, old protuberance; b, newly-formed lump caused by inflammation."

I am, Sir, yours truly,  
OSCAR JENNINGS.

#### SUPPURATION IN THE ACCESSORY NASAL SINUSES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In his admirable clinical lecture on the above subject, Dr. James Donelan seems to have overlooked or omitted to mention the large class of cases of suppuration in the antrum due entirely to dental causes. During the past twenty years I have seen scores of such cases. The diagnosis has always been made by surgeons, who have sent the patients to me in order to have the antrum opened through the dental alveoli, extraction of a tooth when called for, and the construction of a drainage instrument through which syringing of the cavity can be carried out. The ætiology of these cases is simple. The roots of several teeth approach the floor of the antrum, and are often covered only by a very thin layer of bone. Abscess around such roots is very liable to burst into the antrum. Very often the apices of the affected roots become at once necrosed; necrosed root, like necrosed bone, keeps up a discharge of foul pus. This accumulates constantly on the floor of the antrum; it cannot flow out until it reaches the level of the ostium; it often, no doubt, infects the whole mucous lining of the cavity, and gives rise to what may be truly called an empyema. The pulps of the involved teeth are always dead owing to exposure and inflammation following caries. Sometimes the teeth are filled, the pulps having been removed by a dentist. Very often the teeth are painless, or only very slightly tender, the free escape of pus into the antrum doing away with the usual signs of "gumboil," as well as preventing severe pain. There are, however, very often the characteristic pains of antral empyema, localised or neuralgic; and, besides this, the chief symptom is flow

of foetid pus from the nostril of the affected side, especially when the head is bent forward. The vast majority of such simple cases yield to treatment—the extraction of the tooth and the daily washing out of the antrum with disinfectants of suitable kinds.

I am, Sir, yours truly,

A DENTAL SURGEON.

London, W., November 4th, 1909.

P.S.—I trust you will allow me to conceal my name. I am a little sensitive in the matter of personal advertisement.

#### THE ETHICS OF JOURNALISM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—An illuminating side-light on the ethics of newspaper proprietorship is provided by Lord Bray's Indecent Advertisements (Amendment) Bill, which has now been printed, with the following explanatory memorandum:—

The object of this Bill is to strengthen the law against the publication of improper advertisements. The Indecent Advertisements Act of 1889 has had considerable effect in preventing the distribution of certain classes of unsavoury advertisements, but the definition of indecent advertisements in that Act has been found not to be wide enough to cover a number of advertisements of a character similar to those struck at by the Act. And while powers exist under the Post Office Protection Act of 1884 for preventing the circulation of such matter by post, there are no adequate or summary means of suppressing the publication in newspapers of advertisements which it is illegal to distribute in the streets.

The necessity for this Act goes to prove what Mr. Sewill in his paper this week suggests, namely, that a great number of newspaper proprietors are dominated by what is nowadays styled "commercialism"; they consider every means legitimate in money-making, so long as it does not render probable a criminal prosecution.

Yours truly,  
AN OBSCURE PRACTITIONER.

November 6th.

#### SPECIAL ARTICLES.

##### HEALTH OF DUBLIN.

SIR CHARLES CAMERON, Superintendent Medical Officer of Health of Dublin, has addressed to the Lord Mayor a letter dealing with the state of public health and sanitation in the city.

From the Report, it appears that there has been a reduction in the death-rate of Dublin, both from all causes and from the zymotic diseases, during the last quarter of a century. In the five years ended 1883, the mean death-rate from all causes was 34.26 per 1,000 persons living, and the zymotic death-rate was 5.84. In the five years ended in 1908, the death-rate was 23.8, including a zymotic death-rate of 1.98. Nevertheless, the general death-rate was far in excess of the mean death-rate in the English towns. In 1908 the mean death-rate in the 76 largest English towns was 15.8; the rate in Dublin was 23. The highest urban death-rate in England—namely, 19.8—was in Oldham. The zymotic death-rate averaged in the 76 English towns 1.59, or, excluding London, 1.67; the rate in Dublin was 1.9.

In some years (Sir Charles states) the infantile death-rate has been slightly lower in Dublin than in the English towns, *minus* London. In 1908 it was higher. The deaths of infants under one year of age were in Dublin 146 per 1,000 births. In London the rate was 113, and in 75 large towns 134. The rate in Dublin should be lower, as mothers are far less occupied in industries which would prevent them from nursing than is the case of most English towns.

The high adult mortality is believed to be due to a larger number of very poor in Dublin than in most English or Scottish cities. In order, to some extent, to counteract the effects of poverty, Sir Charles sug-

gests certain measures which should be taken in hand by the Corporation:—

(1) A considerable extension of the provision of healthy dwellings for the working classes, and especially of the very poor ones.

(2) The regular cleansing of the hundreds of streets, lanes, courts, etc., not in charge of the Corporation.

(3) The medical inspection of school children, and power to provide meals for those found to be insufficiently fed.

(4) Provision for the housing of poor consumptives still at work, and of those unfit to labour.

(5) The efficient carrying out of the object of the Early Notification of Births Act.

Sir Charles lays great stress on the necessity for the better housing of the poorer classes, large numbers of whom at present live in rooms rented from 1s. to 2s. 6d. a week. No doubt, he says, there would be some loss to the ratepayers in providing such housing accommodation, but is it not generally admitted that the poorest and most dependent sections of the community naturally expect to receive help from the more fortunately circumstanced classes? There is no city in these countries which requires a more extensive system of housing improvement to be carried out than Dublin.

The Report urges the Corporation to deal with the cleansing of the 900 streets, lanes, alleys, courts, passages, etc., not in their charge, and pointed out that the cost could be recovered from the owners of the property abutting on the streets, lanes, etc. The dwellings in these lanes, etc., were occupied by about 12,000 persons.

In conclusion, the Medical Superintendent Officer of Health suggests that Parliamentary powers should be obtained to (1) deal with derelict places; (2) the medical inspection of children; (3) the compulsory closing of primary schools during epidemics, chiefly affecting children; (4) the power to supply milk to the infants of the very poor; (5) to empower the Corporation to provide rooms for poor consumptives in the houses in which their families reside; and (6) to define what is a public sewer and what is a private drain.

## MILITARY & NAVAL MEDICAL NOTES.

**CONVALESCENT HILL DEPOTS IN INDIA.**—A salutary arrangement in regard to the time for transferring men from the hill depôts to the plains of India is now in force. In former times these cases, sent to the hills early in the hot weather, used to be sent to the plains early in October, when the weather was still muggy and hot, but now the transfer is, very properly and fitly, to be made as late as November 1st, or even up to the 15th of that month.

**DENTAL SURGEONS FOR THE NAVY.**—The Admiralty have approved of three civilian dental surgeons being employed at Chatham, the present dental surgeons doing the necessary work at the Royal Naval Hospital, Royal Marine Barracks, and for all marines from ships. Two dental surgeons, working in different rooms at the Royal Naval Barracks, are to divide the remainder of the dental work of the port between them, one visiting Sheerness as occasion requires for examinations and minor dentistry. Two civilian dentists are to be employed in future at Shotley, and one whole-time civilian dentist at the Royal Marine Depôt, Deal. If possible, every man and boy on home service will be examined and treated, when necessary, once a year. All this has become necessary owing to the large invaliding on account of defective teeth.

It seems odd that at this late date the Under-Secretary of State for the Navy in France should direct that every sailor should be provided with a medical history sheet, on which should be entered a variety of particulars about the man, when in our

Services, both military and naval, a system such as this has existed for many long years. These sheets are always transferred with each man's transfer from corps to corps, or ship to ship, and give particulars as regards height, weight, chest girth, vaccination, dates of admission and discharge, days in hospital, disease, treatment, etc. In the case of the French, some more stringent rules are directed in the transfer of medical history sheets under sealed orders, and in diseases of a "confidential nature" (whatever these may be) being denoted by a number contained in the nomenclature used for the purpose.

**BOARDS OF HEALTH AND THE FRENCH NAVY.**—A circular has lately been issued by the Naval Under-Secretary of State, establishing Boards of Health in the Naval ports, the chief Board's location being in Paris, at the Marine Ministry, comprising four civilian members of the U.S., of States selection, and four Naval members, one being the Surgeon-General of the French Naval Medical Service (*Service de Santé*). A pharmaceutical chemist in charge of the analytical laboratory of the Central Store department of the Navy is also a member. Boards in each port will be comprised of eight members, including the Medical Director-General of the garrison and the bacteriological expert of the port. These measures cannot but be attended with the best results, for of late the drinking water in some places has been found impure, and in one (Cherbourg) caused isolated cases of enteric. Fortunately, extension of disease was prevented by prompt measures.

**RESULT OF WAR RATION TEST.**—The result of the test alluded to in our issue of October 27th is said to be satisfactory physically. Some men, though losing flesh, as was to be expected, retained their strength. None were specially selected for the experiment, as it was desired to secure average results. The men were all 20 years of age and upwards; several had reached 30, and all were trained soldiers. Smoking was discouraged, and intoxicating liquors were not supplied; neither were they allowed to be purchased. The men have been granted additional pay, and have been thanked for offering themselves for the test and abiding by the regulations issued. The medical report so far as the condition of the men generally is concerned, broadly summarised, may be put down as follows:—First, loss of weight due to absence of butter, cheese, milk, and of sufficient fatty foods; second, neuralgia caused by run-down system, insufficiently nourished; third, headache, indigestion, etc., due principally to absence of green vegetables.

## MEDICAL NEWS IN BRIEF.

### Scarlet Fever from Cows.

The London County Council have issued a report by their Medical Officer submitting a report by Dr. W. H. Hamer and Dr. T. Henry Jones on an outbreak of scarlet fever last June in London and Surrey, and a bacteriological report by Dr. Mervyn Gordon.

According to Sir Shirley Murphy's report, the outbreak affected upwards of 400 persons, who consumed milk obtained from a particular milk company. He discusses the two hypotheses of human or bovine origin for the fever. The former hypothesis is dismissed, as careful inquiry failed to yield any evidence of a human source of infection.

On the question of bovine infection the report says:—"Under similar circumstances Sir William Power, in 1882, when investigating an outbreak of scarlet fever in certain London districts, made the suggestion that inasmuch as 'there is one sort of relation between scarlatina and accidents of the puerperal state, another sort of relation becomes comparatively easy of belief,' in fact, that 'if scarlatina in man have other animal source than human source, it may be that one such source is the cow that has recently calved, a cow either not at all ill (except for her par-

turition), or not so obviously ill as to prevent her milk being used for human consumption.' The suggestion thus tentatively made in 1882 at once assumed large importance upon the demonstration by Sir William Power, in 1885, of the bovine origin of scarlet fever occurring in persons consuming milk from a Hendon farm, the cows at which were affected with an eruption of the teats and udder. A similar development of scarlet fever in man, associated with the consumption of the milk of similarly affected newly-calved cows, has been observed in a number of instances since that date. In London in 1892, and again in 1894 and in 1902, considerable prevalences of scarlet fever due to infected milk were strongly suspected to have been originally of bovine origin. In the present instance a like possibility was necessarily entertained, and it has been found possible by study of the farm operations, in minute detail, to show that just at the time when the milk first began to show infectious property, there was added to it the milk of three recently calved cows, the calf of one of which had died after being suckled by the cow for four or five days. These circumstances, together with the fact that the three cows mentioned, and other cows at the farm, showed at the time of the inquiry appearances upon their teats and udders suggestive of Hendon disease, render it probable that a morbid condition of the cow was responsible for the subsequent human illness."

#### Cats and Plague.

THE Authorities of the German colony of Togo have issued a decree ordering that in public buildings in the colony where natives congregate—such as schools, hospitals, or prisons—cats are to be kept officially. The explanation of this order is contained in a decree of the Governor of the colony dealing with the danger of the introduction of plague into Togo from the British Gold Coast. The Governor says the bacteriologist, Dr. Koch, had reported successful experiments made with cats for the eradication of rats in plague-infected and plague-menaced harbours of China. In Hong Kong orders had already been issued providing for the maintenance of one cat in every house, and three cats in larger houses. An investigation made by the German Government at Lome, Togo, showed there were rat-eating cats there, and that the rats were not generally to be found in houses where cats were kept. It is therefore officially advised that the number of cats in the coastal towns primarily exposed to plague-danger, should be increased. Besides appointing official cats to public buildings in the colony, the Government recommends all Europeans and natives to adopt this precaution against plague.

#### Memorial to Professor Cunningham.

A WELL-ATTENDED meeting was held in the Medical School, Trinity College, Dublin, last week, to inaugurate a memorial to the late Professor D. J. Cunningham, the Provost in the chair. The following resolutions were adopted:—

"That a memorial to the late Professor Daniel John Cunningham be organised to commemorate his connection with Dublin University."

"That the friends and former pupils of Professor Cunningham be invited to subscribe to the memorial—subscriptions not to exceed £2 2s."

"That the memorial take the form of a medal and prize to be awarded to the candidate who obtains highest marks in Anatomy at Part I. of the Intermediate Examination held in June; and, further, that a portrait in bronze of the late Professor be placed in the school."

"That a General Committee be formed of those present, together with such other subscribers as may desire to act; and that the following constitute an Executive Committee to carry out the resolutions of this meeting:—The Regius Professor of Physic, the Regius Professor of Surgery, the Hon. Mr. Justice Boyd, the Right Hon. Jonathan Hogg, Dr. A. C. O'Sullivan, Mr. E. J. Gwynn, and the four chief demonstrators of Professor Cunningham."

Those who spoke at the meeting were Dr. James Little, Regius Professor of Physic, the Dean of St.

Patrick's, Mr. Justice Boyd, Dr. A. C. O'Sullivan, Sir Charles Ball, Regius Professor of Surgery, Mr. E. J. Gwynn, Dr. A. F. Dixon, and Dr. T. J. Moorhead.

#### Hemel Hempstead Workhouse.

AT Hertford. on Saturday last, in charging the Grand Jury, Mr. Justice Lawrance referred to the charge of manslaughter against May Rose Bellamy, one of the nurses at the Hemel Hempstead Workhouse Infirmary, for causing the death of an old man named Edward Allmond by bathing him while he was suffering from bronchitis on October 4th. His lordship said Allmond was admitted to the workhouse in the ordinary way, and after being there for two or three days it was reported that he was unwell, and he was removed into the infirmary ward. He was not sent there as a man suffering from some disease or for whom any particular treatment had been prescribed. But in this case there was no intimation from the doctor that there was anything the matter with him. The bath was administered in the usual way, under the supervision of the porter, but the effect of it was that the man died the same day. Then it was said by the nurses that that was the first time they had heard that he was ill. The question for the Grand Jury was whether this woman was guilty of such culpable negligence as to constitute a *prima facie* case of manslaughter against her.

The Grand Jury threw out the bill, and the accused was discharged.

#### Metropolitan Counties Branch British Medical Association.

THE Council of the Metropolitan Counties Branch have made arrangements for a meeting at which the direct representatives (for England and Wales) of the profession on the General Medical Council, Drs. Langley Browne, Latimer and McManus, will address their constituents who reside in London and the neighbourhood. The meeting will be held on Monday, November 22nd, at the St. James's Vestry Hall, Piccadilly, W. (close to Piccadilly Circus), at 4.30 p.m. All members of the profession are invited to attend.

#### The Red Cross.

THE Duchess of Portland should have presided over a meeting at Nottingham on Saturday to organise a branch of the Red Cross Society, but her Grace was unavoidably absent. The Duke of Portland, however, attended, and commended the objects of the society to a gathering thoroughly representative of the city and county. Colonel McPherson, of the War Office, thoroughly explained the scheme for organising voluntary-aid detachments of men and women in case of military operations being carried on in this country, and said the most important feature of such work was concerned with the transport of the wounded.

#### A Workhouse Scandal.

THE Chairman of the Isle of Wight Board of Guardians, Alderman Fellows, denies the statement attributed to him that he saw patients dying by the side of the bed in the workhouse infirmary. An inquest will be opened on the body of an epileptic patient of the infirmary who died in fits.

THE EARL OF ARRAN, K.B., Sir James Crichton-Browne, M.D., F.R.S., and others, received a party of scientists, on Saturday, at the Bovril Factory in Old Street, E.C. The guests included Professor Kenwood and the members of the South-Eastern Section of the Sanitary Association. The visitors were conducted in parties over the premises of the company. The laboratories, where the raw materials are subjected to the scrutiny of experts, were then inspected, and the visitors were shown the concentrated beef materials in the form in which they arrive direct from the factories of the vast Bovril estates of some ten million acres.

In the milling-room was seen the preparation of the albumen and the fibrin—the feeding part of the beef—and it was interesting to note that, during the whole process of manufacture, Bovril is never once touched by hand.

## NOTICES TO CORRESPONDENTS, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

### SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs 15.12. Messrs. Dawson and Sons are our special agents for Canada.

### ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £3 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 53 insertions at £2, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

THE first of the new series of popular Saturday night lectures at Sheffield University was given by Dr. Herbert Henry on Saturday. His subject was, "The Romance of Modern Medicine." Dr. Henry said it was owing to the courage of Lady Mary Wortley Montagu, whose husband was ambassador at the Porte, that in the 18th century inoculation against small-pox began to be practised in England. The Brahmins and the Chinese, ten centuries before Christ, had employed similar methods. The method was dangerous, since the actual small-pox germ was used sometimes with fatal results. The cow-pox inoculation discovered by a Gloucester farmer, really started the present almost universal system of vaccination. It was strange, commented Dr. Henry, that in Gloucester now there should be a colony of people violently opposed to it. Of the value of it there could be no doubt whatever on the part of those who would look facts in the face. The discovery of germs might be said to have revolutionised medicine. In France last century, anthrax broke out amongst cattle in a terrible form, and in some cases shepherds also succumbed. That led to the discovery of bacilli. In the field of investigation opened up by that discovery, a young Frenchman named Coque had done great work. He had facilitated examination by straining bacilli, and by discovering that they could be made to grow outside the human body. Following upon this came to light one of Nature's great truths, that Nature always set up resistance to the inroads of disease, or, in other words, provided a counter-agent or anti-toxin. In exemplification of this, Dr. Henry spoke of the effect of rowing upon the hands of a man unused to the exercise. Blisters were raised, but if the exercise were discontinued before a sore resulted, and renewed only after a certain interval, the skin became hardened. Thus the poison of a disease, if administered in a mild form and at stated intervals, produced, in contact with the resisting force in the blood, an anti-toxic effect.

## Meetings of the Societies, Lectures, &c

### WEDNESDAY, NOVEMBER 10TH.

HUNTERIAN SOCIETY (17 Finsbury Circus, E.C.).—8.30 p.m.: Dr. A. C. Jordan: X-Rays Diagnosis for the Physician.

UNITED SERVICES MEDICAL SOCIETY (Royal Army Medical College, Millbank, S.W.).—5 p.m.: Clinical Demonstration.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m.: Mr. P. J. Freyer. Clinique (Surgical). 5.15 p.m.: Lecture: Mr. H. S. Collier: The Surgical Complications of the Inflammations of the Colon.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Clinics: 2.30 p.m.: Medical Out-patient (Dr. T. R. Whiphram); Skin (Dr. G. N. Machen); Eye (Mr. R. P. Brooks). 3 p.m.: X-Rays (Dr. H. Pirie).

### THURSDAY, NOVEMBER 11TH.

ROYAL SOCIETY OF MEDICINE (OBSTETRICAL AND GYNECOLOGICAL SECTION) (20 Hanover Square, W.).—7.45 p.m.: Specimens will be shown by Dr. Arthur Giles and Dr. T. G. Stevens. Paper: Dr. Comyns Berkeley and Dr. Victor Bonney: Leukoplakia Vulvitis and its Relation to Kraurosis Vulvæ and Carcinoma Vulvæ, with epidiascopic demonstration.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11 Chandos Street, Cavendish Square, W.).—8 p.m.: Card Cases by Mr. S. Stephenson, Mr. R. D. Batten, and others. 8.30 p.m.: Mr. W. M. Beaumont: Oxycephaly.—Mr. W. B. Harman: (1) The Measurement of the Desire for Binocular Vision by Means of the Diaphragm Test; (2) The Measurement of Hyperphoria by Means of the Diaphragm Test.

HARVEIAN SOCIETY OF LONDON (Cafe Royal, Regent Street, W.).—7 for 7.30 p.m.: Annual Dinner.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY (Board Room of the Great Northern Central Hospital, Holloway Road, N.).—9 p.m.: Clinical Evening.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.).—4 p.m.: Sir Jonathan Hutchinson: Clinique (Surgical). 5.15 p.m.: Lecture: Dr. L. Smith: The Treatment of a Failing Heart.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynecological Operations (Dr. A. E. Giles). Clinics: Medical Out-patient

(Dr. A. J. Whiting); Surgical Out-patient (Mr. Carson). 3 p.m.: Medical In-patient (Dr. G. P. Chappel).

### FRIDAY, NOVEMBER 12TH.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6 p.m.: Chesterfield: Lecture: Syphilis (continued): Papular (I., Miliary; II., Lenticular; III., Squamous; IV., Moist), Pustular and Tuberculous.

ROYAL SOCIETY OF MEDICINE (CLINICAL SECTION) (20 Hanover Square, W.).—8 p.m.: Cases will be shown by Mr. A. Pearce Gould, Dr. Lunn, Dr. Rolleston, Dr. Galloway, Dr. T. D. Savill, Dr. Poynton, Dr. Salusbury McNalty. Report: Mr. A. Carless: Intestinal Concretion (shown at last meeting). Papers: Dr. Gifford Nash: Primary Hyperplastic Tuberculosis of the Stomach and Duodenum. Dr. Hale White, Dr. Bruce-Porter, and Mr. Lockhart Mummery: A Case of Pneumococcal Colitis with Hyperpyrexia, Severe Hemorrhage treated by Appendicectomy.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.).—4 p.m.: Dr. H. Tilley: Clinique (Ear, Nose, and Throat).

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinic: Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Operations Clinics: Medical Out-patient (Dr. A. G. Auld); Eye (Mr. R. P. Brooks). 3 p.m.: Medical In-patient (Dr. R. M. Leslie).

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn Road, W.C.).—3.45 p.m.: Lecture: Dr. A. Wylie: Larynx.

### MONDAY, NOVEMBER 15TH.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m.: Dr. James Galloway: Clinique (Medical). 5.15 p.m.: Dr. J. L. Bunoh: "Tubercular Diseases of the Skin, and their Treatment."

### TUESDAY, NOVEMBER 16TH.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m.: Dr. C. Theodore Williams: Clinique (Medical). 5.15 p.m.: Dr. Wardrop Griffiths (Leeds): "On Some Cases and Specimens of Unusual Diseases of the Heart."

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn Road, W.C.).—3.45 p.m.: Dr. J. Atkinson: Nose.

## Appointments.

BLACKWOOD, WILLIAM, M.B., Ch.B. Edin., Honorary Medical Officer to the Camborne (Cornwall) Dispensary.

CLARKE, HENRY J., jun., M.B., B.C. Cantab., M.R.C.S., L.R.C.P. Lond., Honorary Surgeon to the Doncaster Royal Infirmary.

DOCKRAY, J. S., M.D., Ch.B. Viet., Certifying Surgeon under the Factory and Workshop Act for the Bishop Stortford District of the county of Hertford.

FLETCHER, H. N., M.B., B.S. Edin., Senior Assistant Surgeon to the Sussex County Hospital.

HOARE, EDWARD F., M.D., Ch.B., L.S.A., Honorary Assistant Surgeon to the Cancer and Skin Hospital, Liverpool.

McLAREN, MAUD V. EVERETT, L.R.C.P. and S. Edin., L.F.P.S. Glasg., Part-time Medical Officer to the School Board of Glasgow.

POOLEY, GEORGE H., F.R.C.S. Eng. and Edin., Lecturer in Ophthalmology in the University of Sheffield.

THOMAS, JOSIAH TELFER, L.R.C.P. Lond., M.R.C.S., Medical Officer to the Camborne (Cornwall) Dispensary.

VERRALL, T. J., M.R.C.S., L.R.C.P. Lond., Honorary Consulting Surgeon to the Sussex County Hospital.

## Vacancies.

The Hospital for Sick Children, Great Ormond Street, London, W.C.—Fourth Anesthetist. Honorarium of £15 15s. voted on the expiration of each year of office. The sum of £6 6s. is also voted to provide a substitute during three weeks in the summer. Applications to the Secretary.

Kent County Asylum, Chatham.—Third Assistant Medical Officer. Salary £145 per annum, with board, quarters, attendance, and washing. Applications to Medical Superintendent, Chatham, near Canterbury.

Nottingham General Dispensary.—Assistant Resident Surgeon. Salary £160, with apartments (not board), attendance, light, fuel. Applications to G. Cheeseman, Secretary, 12, Low Pavement, Nottingham.

Nottingham General Dispensary.—Resident Surgeon. Salary £180. With apartments (not board), attendance, light, and fuel. Applications to C. Cheeseman, Secretary, 12, Low Pavement, Nottingham.

City of Birmingham.—Salterley Grange Sanatorium for Consumptives, near Cheltenham.—Medical Superintendent. Salary £250 per annum, with board. Applications to the Chairman of the Health Committee, Council House, Birmingham.

## Births.

DENNY.—On November 4th, at R.N. Hospital, Cape of Good Hope, the wife of Staff-Surgeon H. R. H. Denny, R.N.—a son.

## Marriages.

ALLEN—CRONIN.—November 6th, in London, Samuel Carson Allen, fourth son of the late David Allen, J.P., Belfast, to Carrie, only daughter of the late John Cronyn, M.D., Dublin.

WALKER—LE BRETON.—On November 4th, at All Souls' Church, Langham Place, London, Robert Wynne Stanley Walker, M.B., B.C., youngest son of Theodore Walker, Glenn Hall, Leicestershire, to Alice May, only daughter of C. M. le Breton, K.C.

## NOTES AND COMMENTS.

### Another Martyr to Medicine.

A FEW weeks ago it was our privilege to comment in these columns on the distinguished bravery of a South Wales colliery surgeon. This week it falls to our lot to record the death of another of our colleagues who sacrificed his life in a less dramatic way, it is true, than that of leading a forlorn hope through the bowels of the earth, but none the less surely was it laid down freely before the altar of duty. The name of Dr. John Herbert Wells is now added to the long list of medical men who have laid down their lives in the cause of humanity. For some years past he had been engaged in special research work at the St. Mary's Hospital laboratories. He had specially devoted himself to the study of glanders, and, we believe, actually achieved successful results in the case of one patient. Unhappily, he himself contracted the disease, and after eighteen months' suffering, has died, at the early age of thirty years. He has left behind him a widow and two small children, on whose behalf a fund has been started. Contributions will be acknowledged by the *Lancet* or by the honorary secretaries, Lord Dalhousie, or Mr. Julian Lousada, at 18 Old Broad Street. There should be no difficulty in securing an ample public recognition of the splendid self-sacrificing altruism shown by the late Dr. John Herbert Wells.

### The Regulation of Vice.

THE Manchester and District Society for the Abolition of the State Regulation of Vice, at their recent annual meeting, asked a few pertinent questions and advanced certain views that smacked of fine old mediæval intolerance at its prime. To purists of this kind "vice" means one thing only, and that is sexual indulgence, apart from marital relationship. The secretary, a clergyman, raised the important question whether England, which did not allow of State regulation of vice in her garrison towns at home, should nevertheless adopt that principle abroad in the military stations of South Africa, India, and other British settlements. That problem has vexed other than clerical brains. Years ago—when a salutary British law attempted to control one of the most deadly of the infectious diseases that afflict our home society—the Government of the time was weak enough to abolish the Act, with the result that venereal disease has since been unrestrainedly at work, like the deadly leaven that it is, among all classes of the United Kingdom. Another point that stirred up still warmer resentment in the mind of the reverend secretary were the experiments of Neisser and Metchnikoff in the endeavour to establish immunity against syphilis, or, as the society with the long name

prefers to speak of it, the "fruits of vice." The chairman took up the story, and emphatically condemned the suggestion that schoolboys should be compulsorily vaccinated against syphilis, as they are now against small-pox. That suggestion, however, appears to be as far in front of the times as the views of the Manchester society lag behind what we perhaps speak of as the collective common-sense morality of the nation. However, it is never likely to come on the stage of practical politics, as it may be confidently anticipated that syphilis will be eradicated within the course of a few generations.

### Syphilis an Incurable Disease.

THE fact is that the views of these amiable, but narrow, apostles of virtue are based on faulty data and illogical reasoning. The chairman, for instance, spoke of syphilis as an "incurable" disease. Now, if there be one triumph of modern scientific medicine greater than another it is that which demonstrated the complete curability of syphilis. Yet the speaker held it up as a terrible infection, "the milder equivalent of which might pollute the blood of the nation." Surely that is a strong argument for attempting to check its spread, as we have done in the case of other specific infective maladies. The attitude of the society appears to be that it is wrong to attempt to stop the spread of venereal diseases, regardless of the havoc they spread through society. The implication is that those who contract specific diseases through sexual indulgence should drain their cup of punishment to the last bitter dregs with one hand, while with the other they sternly ward off the ministration of curative medicine. Incidentally, no government, from their standpoint, is warranted in attempting to regulate or restrict in any way the methods of indulgence in the Circe cup. The unhappy fact is that the brunt of the "punishment" falls upon the innocent persons, wives and children, who are secondarily infected. Could any member of the society explain how a man deserved syphilis contracted from drinking from a tumbler infected by a soldier who had picked up the disease in the Antipodes? Possibly the society may crack this hard nut at their next annual meeting!

### "Dr." Walford Bodie.

NEMESIS of a kind popular in the backwoods has followed hard on the heels of the recent exposure of the methods adopted by the so-called "Doctor" Bodie in the law courts. That well-known music-hall irregular practitioner of medicine admitted in the witness-box that the meaning attached to the letters M.D. after his name was "Merry Devil"—nothing more and

nothing less. However passable this may be as a music-hall quip, it is not likely to save any man's bacon in a higher court of law—although from long experience it would be impossible to predicate what view a magistrate might take if asked to adjudicate upon the joke under Section 40 of the Medical Act, 1888. Medical men, it must be admitted, are much to blame for their want of defensive organisation and their indifference to music-hall and other unqualified trespassers. Medical students, on the other hand, still live in some association with each other, and do not shrink from applying the rough-and-ready methods of border justice. In this way the Glasgow students last Thursday took possession of the Glasgow Coliseum, and saluted "Dr." Bodie when he came on the stage with a fusillade of eggs, bananas and other missiles. Bodie fled, the stage was stormed, the police for the moment ousted, and the leader of the students induced Bodie to appear and publicly apologise for having called them "beggarly Carnegie students from Gilmorhill." Bodie was warned never to appear again in Glasgow, and the "1,400 infuriated students," as they are termed in one London newspaper, left the building quietly. We are sorry we cannot for one moment countenance these unruly proceedings.

**The Queen Alexandra Sanatorium at Davos.** THE new sanatorium at Davos for British consumptives, which has been built under the patronage of Her Majesty Queen Alexandra, and is permitted to bear her name, has been built of stone from the neighbourhood of the site, with ferro-concrete floors, roof, staircases, and balconies. The walls of the foundations, cellars, and basements are of immense thickness, and the main walls are nowhere less than 2 ft. The building is situate close to Davos Platz, on the mountain side, about 300 ft. above the town of Davos, whence it is reached by an approach road about a kilometre in length. It faces about S.S.W., and commands a charming view of the valley and mountains. The pine forest stretches almost to the doors, and affords a variety of sheltered and accessible walks. The sanatorium contains accommodation for 54 patients; but the public rooms, kitchens, cellars, and store rooms have been planned for the requirements of 120, and the building can be enlarged to afford more bedrooms if such a course should become desirable in future. A new feature of the construction is that each patient will have a separate room, divided from others by a substantial stone wall; and it is, perhaps, only those who have had experience of a sanatorium, from a patient's point of view, who will fully appreciate the increased comfort afforded by this arrangement. The extra work involved has added largely to the cost; but the managers are convinced that the results will be of commensurate value.

## LEADING ARTICLES.

### EUGENICS AND PAUPERISM.

THERE are many obstacles, social and intellectual, in the path of the scientific breeding of mankind. Hitherto the evolution of man has been for the most part left to the operation of natural laws, thus the full meaning and extent of which are as yet imperfectly understood. Nor is it likely that mankind will readily abandon the fixed prejudices and beliefs that have created the present system of society whereby and wherein his race is propagated. On the other hand, many persons will be found ready

to assent to the proposition that on abstract grounds it would be well were mankind to take in hand the control of the natural conditions which determine the characters of human offspring. In other words, that a method of artificial selection in the breeding of an ideally perfect race should replace, or, at any rate, profoundly modify the existing haphazard and uncontrolled forces. That, or something like it, appears to be the position of the Eugenic Society, and there is undoubtedly much to be said in its favour, however much it may run counter to orthodox and established beliefs and prejudices. It would be difficult for any candid man, however detestable to him might seem the attempt to reduce the marriage relations to a basis of calculated procreation, to deny the desirability of ridding the community of many of its burdens, of the wreckage of society to be found in its hospitals, gaols, workhouses, prisons and lunatic asylums. In ancient Sparta it was the custom to destroy all deformed, or otherwise unfit, children at birth, and a similar custom, we believe, prevails at the present day in some parts of the world. Quite recently it has been suggested, apparently in all seriousness, that a similar principle should be adopted, to a certain extent, by exterminating our adult imbeciles. The mayor of a southern town, who was responsible for advocating the euthanasia of all hopeless imbeciles, certainly was not disappointed at the storm of abuse to which he anticipated his views would give rise. The upholder of the science of eugenics takes a less assailable position when he treats the matter logically and endeavours to prevent the production of unfit offspring. Indeed, so difficult is it to reconcile the intellectual conclusions with moral convictions that we can readily conceive the follower of eugenics holding up his hands in horror at the thought of deliberately consigning his imbecile fellow creatures to the lethal chamber, while the upholder of the latter procedure would shudder at the idea of applying the principles of artificial selection to mankind. If we turn to the facts of society we find that the modern tendency is to foster to the utmost of their capacity all who are unfitted by Nature or by accident to take their part in the struggle for existence. Nay, more than that, the collective wisdom of the community has taken no effective steps to prevent the propagation of lunatic and other diseased and degenerate persons. To take an instance, it is well known that lunatics are often discharged from asylums as "cured" only to return after a few years' interval, during which they have been permitted to bring offspring into the world with the taint of insanity hanging over their heads. In such a case a clear logical process of reasoning can hardly fail to lead one to the conviction that, it being against the interests of the community to add to its potential lunatic population, asylum patients should be kept under such restrictions that would render their procreation of children impossible. Dr. Rentoul adopted the extreme attitude of advocating the sterilisation of all such persons, but it should not be beyond the wit of man to devise some method of detention that would attain the same end. The old adage about marrying in haste and repenting at leisure

contains a vast deal of condensed philosophy. Nowadays the tendency amongst the intelligent and thoughtful section of the community is to recognise more and more the fact that marriage entailed obligations, not only as regards husband and wife, but also as regards the children and the State generally. In a recent lecture on "Eugenics and Pauperism," Sir Edward Brabrook pointed out that the ill-nourished, ill-trained people of our large cities turned out of their miserable homes to marry early. They made no calculations of their responsibilities, and the results were that a numerous and degenerate progeny was brought into the world. The old rule of the survival of the fittest, said this authority, had been to a great extent repealed as the result of modern tendencies. And thus he came round to his great gospel that the breeding of human beings was a science, and that general education on eugenics was a social necessity. If their faith be founded on a rock, we have no doubt that in the fulness of time it will influence the mind of the nations. Meanwhile, the most hopeful optimist of us all must confess that there is something wrong in the scheme of society which encourages and fosters the multiplication of the hopelessly unfit and permits them to contaminate the vigour of coming generations.

#### THE RECENT HEMEL HEMPSTEAD MAN-SLAUGHTER CASE—A SEQUEL.

THE facts of the recent trial of a nurse for manslaughter at Hemel Hempstead Workhouse Infirmary will be fresh in the minds of many of our readers. Associated with an injudicious routine application of baths, several deaths occurred, and these were investigated by a coroner's inquest. An adverse verdict was returned against the nurse by the jury and she was at once arrested by the police. After somewhat prolonged judicial proceedings she was declared innocent, and accordingly discharged. Now, under ordinary circumstances this little tragedy would have become a local seven-days' wonder, and then would have quietly dropped out of existence. Possibly the Local Government Board, as the central controlling Poor-law authority, might have had their attention drawn to a fresh defect, or group of defects, in the much-abused system they are called upon to administer, and there the matter would probably have ended. Poor-law nurses have hitherto been powerless to protect themselves when subjected to harsh or unjust treatment, and have had to endure the woes and difficulties of their obscure, but responsible, position in silence. They have, indeed, shared the lot of workers who have not been able to secure for themselves the collective self-help of a trades union. Happily for the future of Poor-law nursing, there exists a protective organisation which has been called into existence within the past few years. Under the patronage of the Princess Christian, ever a kindly champion of those in need of help and encouragement, the officers of the Workhouse Nursing Association have done and are doing good work in the cause of their adoption. As regards the recent Hemel Hempstead case, they have addressed a letter to the Right. Hon.

John Burns, President of the Local Government Board, that cannot fail to attract attention by the firmness, reasonableness and moderation of its statements. With the merits of the internal administration of the Hemel Hempstead Workhouse we are not for the moment concerned. That part of the question may be safely left in the hands of the Central Authority. There is, however, a grave question affecting the administration of British justice raised by the Association. A reference to their letter, which will be found printed in full on page 535 of the present issue, will show that one person held in Hemel Hempstead the post of Clerk to the Guardians, Coroner, and Clerk to the Magistrates. Whatever the precise legal position may be with regard to the tenure of plural posts of that kind, we have little hesitation in condemning it at sight as opening the door to abuses of an obvious character. Upon the facts of the recent Hemel Hempstead case we offer no comment. The Workhouse Nursing Association do not hesitate to attribute bias to the Clerk to the Guardians, whose attention had been unfavourably drawn, they state, to the nurse concerned by her attitude on the question of the nurses' grievances. It seems clearly undesirable, any way, that he should investigate the case as Coroner. Nor do we consider that any coroner, even if permitted by the rules of his office, should sit in prolonged consultation with the jury, as the Association say they are informed he did in this instance. Nor do we agree with his action in not having a post-mortem examination made in a case involving issues of so serious a nature. In the subsequent police prosecution this man of many offices is again found playing a leading part as Clerk to the Magistrates. It is impossible to approve plurality of that kind, and the thanks of the public are due to the Association that has fearlessly drawn attention to its existence. The Association makes some pointed comments upon the appointment of Poor-law nurses to posts for which they are unfitted. As the matters raised are of significance to a large class of medical men, any future developments will be noted with interest.

#### CURRENT TOPICS.

---

##### Medical Men and Midwives' Emergency Fees.

THE medical men of Chelsea and Fulham last week met in the Fulham Town Hall to protest against the action of the local Guardians in declining to accept responsibility for the fees of medical men called in to assist midwives in emergencies. It was unanimously resolved: "That the medical practitioners of Chelsea and Fulham refuse to attend any woman in or immediately after child-birth, or in respect of some puerperal malady or affection, unless the respective Boards of Guardians of Chelsea and Fulham guarantee to pay for the attendance." This outspoken declaration of right must appeal to the sense of justice of all fair-minded citizens. Members of the medical profession have been deprived of the greater proportion of their midwifery cases, which have been handed over to the midwives. Now they are asked

to go to the aid of the midwives in difficult cases, but without any security as to the payment of their fees. The Guardians' position in the matter was placed before the meeting by a medical guardian. He said that so far there had been only fifty-seven such cases, and in only seven had the Guardians refused payment. He pointed out that the Guardians had no legal right to relieve an able-bodied man who was in work. On the other hand, it may be remarked that the Guardians have no right to employ the services of able-bodied and highly-skilled medical men unless they are prepared to remunerate them properly.

#### Memorial to Professor Cunningham

WE were glad to notice, in our last issue, the inauguration of a memorial to the late Professor Cunningham. His life-work was associated with two great universities—Edinburgh, where he spent his youth and his last years, and Dublin, where the best years of his life were passed. We have not heard whether the Northern University is taking steps to perpetuate the memory of her great son, but Dublin owes so much of her recent development to Cunningham that it is right she should not be behindhand in the expression of her piety. We are sure that not only Cunningham's pupils—for whom the cheery face and kindly words of "Dan" are among the most intimate of their student memories—but the many friends who were his colleagues in various public movements, will gladly join to perpetuate his memory. The form decided on is, we think, the form Cunningham would himself have chosen. Moreover, by a medal in the School of Physic, his name will be for ever linked with those of three of his colleagues who have left their mark on the Dublin school—Banks, Bennett and Purser—the last, we are glad to say, still with us.

#### To Anti-Vivisectionists.

THERE cannot be any doubt that during any one day of the hunting, shooting and fishing season in these islands more pain is inflicted upon animals than in all the physiological laboratories together throughout Great Britain during the whole of the year. The sportsmen who are guilty of this cruelty, although they may fully recognise the extent of the suffering they cause in pursuit of their diversions, never seem to be troubled with qualms of conscience. They take it as a matter of course, and it was amusing to notice that at a recent anti-vivisection congress the chairman was himself a well-known salmon angler, a votary of a sport which is only qualified as "good" when the fish, with a hook in gills or gullet, makes a prolonged fight for life and freedom. The spirit of the sportsman is expressed in the current issue of *Country Life*, in an article which, in passing, deals with the economy of grouse moors. In the old days, before "driving" was almost universally adopted, the birds were followed up, and most of those that had escaped wounded were soon accounted for. After a drive, however, wounded birds get away to a lingering death. These, we are told, "may or may not survive the winter; it all depends upon the gravity of their injuries and the severity of the weather." If they die

they do no harm to sport; if they survive they are apt to produce a weakling brood, and for this reason, therefore, they should be killed down. After every battue a considerable percentage of birds and ground game always escape wounded. The keepers employed by some of the noblemen who are among the most active supporters of anti-vivisection societies, could enlighten their masters as to the numbers of wounded pheasants that are discovered during the weeks following a single grand day's "sport," but it would probably be as much as their place was worth to take such a liberty.

#### Should Veronal be Scheduled?

AN alarming number of deaths from the use of veronal, either by accident or by intention, have been reported within the past few weeks. Indeed, the matter has now attained a growth that demands the serious attention of the Government. On previous occasions we have thought it desirable to ask for the scheduling of veronal as a poison by the Pharmaceutical Society. Several of the fatalities have been due to the taking of the drug in pellet form, and most medical men must deprecate the sale of so dangerous a substance in the amounts usually contained in the bottles sent out by the manufacturers. This point may be advanced with confidence so far as the high-class firms from which these particular remedies emanate are concerned. They have only to become acquainted with the dangerous results of offering to the public those particular wares in that particular form to put an immediate stop to their sale. In a recent veronal case at Cardiff the Coroner said he thought there should be some legislation which, without interfering with the legitimate trade of the chemist, should form a protection for the public, whereby these things should not be so easily obtained. On this the jury promptly added a rider to their verdict, calling the attention of the Home Secretary to the need for special legislation. The ideal method were it attainable, would be to forbid absolutely the sale of all deadly drugs, except upon the responsible order of a duly qualified medical man.

#### The "Note" System in Hospitals.

THE moot question of the desirability of the system of "notes" or "letters" of admission to hospitals seems as far from settlement as ever. There can be little doubt that in many instances it inflicts a hardship upon the deserving sick poor, who are put to great trouble and inconvenience in the effort to obtain these recommendations. On the other hand, those who are charged with the heavy responsibility of finding the funds necessary for the support of the voluntary medical charities recognise in this system a valuable attraction to subscribers by offering them patronage of a kind that is often useful and the exercise of which maintains their interest in the particular hospital to which they have given their support. But there need be little hesitation in condemning a modification of the "note" system recently adopted by the West Bromwich and Wednesbury Hospital Saturday Committee. It appears that the local hospital, like many others, is at present staggering under a burden of debt, and handed a supply of notes to the Saturday Committee. The latter determined,

so far as can be gathered from the newspaper report at hand, to limit their notes to workpeople employed at works that have contributed to the Hospital Saturday Fund collections. This is making a lever of a purely voluntary collecting and distributing agency that we venture to affirm was never contemplated by its founders. It is, in point of fact, a covert pay system, inasmuch as the payment of money to the Saturday Fund is made an essential condition of relief. The proposal, to a certain extent, undermines the principle that should dominate the conduct of a voluntary medical charity carried on in the interest of the public.

### The County Medical Officer of Health.

BE the merits or demerits of the present Government what they may, there is little doubt that the effort to protect the position of the county medical officer of health demands the gratitude of the medical profession. In the original Bill for town planning, section 68, sub-section 5, reads: "A medical officer of health for a county shall be removable by the county council with the consent of the Local Government Board, and not otherwise." In the House of Lords the section eventually became number 70, but sub-section 5 still remained as above, but apparently on the ground that the rights of the county councils were being invaded, the sub-section was deleted. It has been replaced by the Commons, but in the course of the debate an endeavour was made to represent the case as a battle between the trade union of the doctors and of the landlords. It would be somewhat difficult to find complete justification for such a view. The truth seems to be that a strong, capable and independent medical officer is as much a necessity to the county as the land itself, and the legislature that adopts any other view is likely to be ploughing the sands, so far as the next generation is concerned.

## PERSONAL.

THE KING has been pleased, on the recommendation of the Secretary for Scotland, to approve the appointment of Sir Thomas Mason to be Chairman of the General Board of Lunacy for Scotland in succession to the Hon. Walter George Hepburne Scott, Master of Polwarth.

Dr. H. S. Lowe's name appears in the list of nominations for Sheriff of Anglesey.

A ROYAL Medal has been presented to Major Ronald Ross, F.R.S., for his researches in connection with malaria.

ONE of the new Knights is Mr. James Matthew Moody, L.R.C.P. Edin., M.R.C.S. Eng., superintendent of Cane Hill Asylum.

MR. C. O'NEILL, M.D., M.Ch., M.A.O.R.U.I., has been elected a Member of Parliament for the South Division of Armagh, Ireland.

WE deeply regret to announce the death of Mr. H. H. Clutton, senior surgeon to St. Thomas's Hospital, which occurred on Tuesday last.

IN answer to many inquiries, we are glad to say that our Editor, Dr. D. Walsh, has almost recovered from the effects of his street accident on November 1st.

MISS ANNIE FLETCHER has received the decoration of the Royal Red Cross in recognition of devoted service rendered by her to Their Majesties the King and Queen since 1902.

SIR DONALD MACALISTER, K.C.B., President of the General Medical Council, will take the chair at the next session, in London, on Tuesday, November 23rd, at 2 p.m.

MR. R. HENSLOWE WELLINGTON delivered a lecture upon Forensic Medicine and Coroner's Law on Wednesday last before the North-East London Post-Graduate College.

WE regret to announce the death, on Saturday last, of Sir William Thomson, C.B., Honorary Surgeon to the King in Ireland, and Senior Surgeon to the Richmond Hospital.

MR. JAMES AUGUSTINE HARAN, M.D. Dub., medical officer of health at Mombasa in the East Africa Protectorate, has been made a Companion of the Most Distinguished Order of St. Michael and St. George.

MR. GEORGE HERBERT POLLARD, M.P., M.D., C.M. Edin., has received a knighthood. He is a barrister-at-law of the Inner Temple, and has been a member of the Eccles Division of Lancashire since 1906.

ON Saturday last Dr. F. Womack, professor of physics at St. Bartholomew's Hospital, formally opened the new observatory and meteorological station which has been erected near the summit of Hampstead Heath.

AT St. Stephens-in-Brannel, Cornwall, Mr. Donald Moore Barry, L.F.P.S., L.M. Glas., L.S.A. Lond., was recently presented with a case of pipes from the members of the local branch of the St. John Ambulance Association.

As a sequel of the mysterious disappearance of Dr. May from the town for the last two or three weeks, the Aston Board of Guardians have resolved to remove his name from the medical officership of No. 4 District.

WE regret to learn that Mr. H. W. Cox, one of the early workers in X-rays, and a well-known maker of apparatus, has undergone an amputation of the forearm. It will be remembered that Mr. Cox recently received a grant from the Government.

THE testimonial to the late Dr. John Herbert Wells, who died from glanders contracted during experimental research work, is being raised by a committee consisting of Mr. Balfour, Lord Dalhousie, Lord Justice Fletcher Moulton, Sir Almroth Wright, and others. Donations to be sent to the *Lancet*, or to the Hon. Secretaries, 16 Old Bond Street, London, E.C.

THE following have been elected Medical Mayors:—Mrs. E. Garrett Anderson, M.D. Paris, L.S.A. (re-elected); Mr. Edward F. Chinery, F.R.C.S. Edin., L.R.C.P. Edin., M.R.C.S. Eng.; Mr. F. H. Appleby, M.R.C.S. Eng., L.S.A.; Mr. R. de la Poer Beresford, M.D. Glas., L.R.C.P., L.R.C.S. Edin., L.R.C.P. Lond.; Mr. E. H. Lipscombe, M.B., B.C. Cantab., M.R.C.S. Eng., L.R.C.P. Lond.; Mr. J. Grout, L.R.C.P. and S. Edin., L.F.P.S. Glas.

THE following members of the medical profession have been elected as Councillors on the London Borough Councils (the list may be incomplete):—Camberwell, Mr. F. Lonnon and Dr. D. M. Serjeant; Finsbury, Mr. W. Lauzun-Brown; Fulham, Mr. J. J. Edwards; Hampstead, Mr. C. W. Cunningham; Islington, Dr. G. Madden and Dr. Kate Haslam; Kensington, Dr. F. H. Anderson and Dr. F. H. Alderson; Paddington, Dr. J. Thoresby Jones; St. Pancras, Dr. R. M. Beaton and Dr. Paramore; Stepney, Dr. Stanley B. Atkinson, J.P., and Mr. M. Feldman; and Westminster, Dr. Henry Dutch.

# A CLINICAL LECTURE

## ON

### VACCINE TREATMENT IN GENERAL PRACTICE.

By ROBERT J. ROWLETTE, M.D.,

Pathologist to Dr. Steevens' Hospital, and to the Rotunda Hospital, Dublin.

I WISH in the present lecture to direct attention to certain methods of treatment which have so directly sprung from work in bacteriological laboratories that they are still left to a considerable extent in the hands of professed bacteriological workers. It is the tendency, however, with regard to all therapeutic discoveries of real utility that they should not remain to be practised only by a certain class of the profession, but should, as time goes on, come into the hands of the rank and file for use in their everyday work. I wish, therefore, to discuss the manner in which the discoveries of vaccine treatment can be applied to some of the common diseases which are dealt with by the general practitioner.

I am not concerned at present to discuss the principles on which vaccine therapy is based. Suffice it to say that by the inoculation of the virus of an infective disease, in suitable dose, we have it in our power to raise the resisting power of the patient toward the particular disease. This is the principle applied for the last hundred years in vaccination for small-pox, but recently it has found much wider application. At present it is applied in the treatment of infective diseases of all sorts where the infection is localised, and is also applied in the prevention of general infective diseases.

The vaccine employed is in most cases a killed emulsion of the causal organism in salt solution, though in the case of tuberculosis, Koch's Tuberculin R. is frequently employed. Let us apply these few general remarks to some of the more common infective diseases of a local nature.

In the first place, I give you particulars of a case of acne. The patient, a student of about 22 years of age, has been troubled with acne spots for many years. He was never entirely without them on his face and back, and at times such a conspicuous crop appeared on his face that he avoided going into ordinary society. This gentleman was given one dose of mixed *staphylococcus aureus* and *albus* vaccine, with the result that the spots almost entirely disappeared. In a few weeks a few spots again began to appear, but a second injection cut them short. At intervals of three or four months he still requires injections, as one or two spots come out on his back, but never has his face again been troubled. This is a typical history of a case.

You will note that I do not mention that any culture was made to discover the causal organism in this case. This omission was, in the first instance, made because the case was urgent, and I felt justified in employing as vaccine the organisms experience has found to be most closely associated with acne. As the vaccine proved immediately successful, cultures were not deemed necessary.

If we may often expect results such as were obtained in the case just sketched, we have obviously at our disposal a mode of treatment of great utility, since all previous methods of treatment of acne were highly unsatisfactory. In my experience we have in vaccine-therapy a mode of treatment always followed by good results in acne, and particularly is the good result marked in the worst cases of the disease.

How, then, should one deal with a case of acne presented for treatment? Two plans are open to us—to cultivate the germ from the pustules, and give a vaccine of that germ, or to give at once, as in the above case, a mixed vaccine on chance. The former is the more strictly scientific method, the latter more haphazard. If the stock vaccine of mixed *Staphy-*

*lococci* be successful, then some time is saved, and therefore, at present, I adopt both courses provisionally. When I see a patient suffering from pustular acne, I take cultures in order to separate the causal organism, but, at the same time, without waiting for the result of the cultures, I give a small dose (250,000,000 cocci) of mixed *staphylococcal* vaccine. (a)

When the cultures have had the necessary time to grow, and the organism has been separated, then a vaccine of that organism should be given for the second inoculation.

A question here arises as to whether it is permissible to use a stock vaccine, or is it necessary in every case to have a vaccine prepared from the strain actually cultivated from the patient? I have no doubt that the latter method will give greater success, but there may be difficulties in applying it in the exigencies of general practice. If it is possible to prepare a vaccine, and if your patient can afford to pay for having it done, then by all means have a vaccine prepared. If not, on satisfying yourself of the organism present—and here it may be necessary to have the help of a bacteriologist—administer a dose of the stock vaccine. At the end of ten days or a fortnight a second dose, double that of the first, may be given, and doses repeated at similar intervals until a cure is effected. In many cases three or four inoculations are sufficient, but it may be necessary for the maintenance of health to give an occasional dose afterward at longer intervals.

There may, however, be indications which render a cessation or modification of the treatment advisable. If any marked local pain or swelling occur at the seat of inoculation, the dose is probably too large, and treatment should be stopped for a few weeks. On resuming, a dose one-fifth of that previously employed is advisable. Again, if fever or general malaise follow an injection, or if exacerbation of the symptoms of the disease occur, the dose is too large. Having once found the dose which suits a particular patient, it is rare that in the course of treatment alteration of that dose is found necessary. In the treatment of women it is advisable to avoid the period of menstruation in giving inoculations. These remarks apply to other infections of which I have to speak presently.

Other cases of local *staphylococcal* infection beside acne occur. For instance, here are particulars of a case treated last year:—A gentleman, a dentist by profession, received a blow of a hockey stick on one of the finger-nails in December, 1907. The nail was broken, and profuse suppuration occurred. His face next became infected, and several small, suppurating patches appeared. Every minute scratch was infected, and several scabs formed, rendering his face unsightly, thus interfering with the practice of his profession. This was his condition when I first saw him some months after the first infection. His finger had just healed. Cultures were made from the sores on the face, and a pure culture of *staphylococcus aureus* obtained. A dose of 250,000,000 cocci of stock vaccine was administered. Within a few days he telephoned to me that he was much better, and when I saw him I found that no fresh spots were appearing, and that the sores were looking clean and apparently healing rapidly. He received a second dose, and a few days later his face had quite healed up, and he has remained quite well since.

Many similar cases are easily and successfully

(a) These stock vaccines are on the market as prepared by several reputable firms.

treated in this manner, as, for example, otorrhœa, surgical wounds which have failed to heal, boils and carbuncles, syphilis, and occasionally gleet. The two cases I have related are sufficiently typical examples of staphylococcal infections.

With regard to streptococcal infections, we find that vaccine-therapy is not employed with quite the same ease as in staphylococcal, since streptococcal infections have a greater tendency to be acute, and vaccines have to be used with more caution in acute than in chronic cases. In erysipelas, however, when it has passed the most acute stage, in protracted septicæmia, particularly of puerperal origin, and in periostitis and endocarditis, treatment by vaccines has given excellent results. In streptococcal cases, however, it is more requisite than in others to have a vaccine prepared from the patient's own strain of organism, since there is greater variety between the different strains of streptococcus than in the case of most other organisms. In the very acute stage of a streptococcal infection, the use of a vaccine is probably not without risk, though it is much more to be justified than is that of the so-called antistreptococcic sera. The initial dose of streptococcal vaccine most commonly found suitable is 5,000,000 cocci.

The form of *bacillus coli communis* infection most frequently met by the general practitioner is probably cystitis, particularly that following the habitual use of the catheter. In cases of cystitis, it is advisable to have the urine examined by a bacteriologist in order to discover the causal organism. Most commonly it is the *bacillus coli*, though sometimes it may be one or other of the staphylococci. The organism being discovered, the treatment is simple, and the prospects are usually good.

Gonorrhœa is another of the common diseases in which the vaccine treatment promises good results. The treatment should not be begun till the acute stage has begun to subside. A dose of 75,000,000 cocci is then given. After ten days double that amount may be given, and further inoculations at similar intervals for a further four or six weeks.

Many cases of gonorrhœa, however, only apply for treatment when the discharge has gone on for many months. Such cases of gleet are notoriously hard to cure by ordinary means. In many cases, too, they resist gonococcal vaccines, and this is due to the fact that the urethra has become the seat of secondary infection by other germs, most frequently the *staphylococcus albus* and *citreus*. In cases, therefore, which are not benefited by gonococcal vaccine, it is advisable to administer a mixture of *staphylococcus albus* and *citreus*. If the first few injections of this are not followed by any improvement, then it is necessary to have cultures made from the urethral discharge. Vaccines from these commonly give good results.

It will be seen that the chief difficulty in treating the urethritis of gonorrhœa arises from the fact that the gonococcus is rarely the only organism present. In certain complications of gonorrhœa, however, we have a pure infection by the gonococcus, and in them vaccine treatment gives the most satisfactory results. The most important of these is urethritis, and in the treatment of this condition one can prophesy speedy cure almost with certainty. Usually two or three injections are sufficient.

The diplococcus of pneumonia is a cause of very varied and widely distributed lesions in the body. Peritonitis, localised puerperal sepsis, superficial abscesses, are among its results. In all such local lesions, treatment by a vaccine of the diplococcus is most beneficial. In the case of acute pneumonia, we are hardly in a position as yet to apply this form of treatment, though in unresolved pneumonia it has been applied with success.

We are left with perhaps the most common and the most important disease—tuberculosis. The variety of its forms naturally make the subject of vaccine treatment one of special complexity.

The most deadly form of tuberculosis is, of course, that which attacks the lungs, and it is precisely here that we are most in the dark as to the conditions under which vaccine treatment is suitable or helpful. Speaking generally, phthisis is the form of tuberculosis in which the treatment has been least successful. This is probably due to the fact that when it has come

under treatment the disease is already considerably advanced. Calls have been made on the reaction of the patient, and it is only when this reaction has failed that the disease has progressed. Now this is precisely the opposite condition to those that are favourable for vaccine treatment. Vaccine treatment is most successful where the disease is so localised that it has failed to call out the reactive powers of the body. To use a figure of speech, we have in local lesions, such as furuncle or lupus, a condition resembling that brought about if a very small foreign force were to effect a landing in some remote point of the coast, and were to remain there unnoticed, ineffective, and entrenched behind strong walls. Their very insignificance is their security. But let the alarm be given, and the posses raised, and the invader is driven into the sea. It is different, however, if the invader has come in such force as to gain possession of the seat of the government and the heart of the country. There is no use in now giving the alarm, or lighting the beacon fire. The country's forces have fought and been vanquished, and any attempt to raise them again only leads to reprisals, murders, executions, and the speedy extinction of the life of the country.

Now, most cases of pulmonary tuberculosis when seen have already arrived at this stage. We find, therefore, that in them vaccine treatment is of little avail, and if persisted in against indications, it may do injury. Nevertheless, in early cases, where the lesion is small, the treatment sometimes is highly useful. It is well, therefore, to try it, but, apart from opsonic estimations, careful attention must be given to the temperature, pulse, and general clinical conditions, and if any ill effect follow, the treatment should cease or the dose be diminished.

In other forms of chronic tuberculosis the matter is simple, and I know none, except, perhaps, nephritis, in which vaccine treatment does not give encouraging results. In lupus, in tuberculous glands, in tuberculous joints, in tuberculosis of bones, in cystitis, in peritonitis, the effect is usually satisfactory, and sometimes startling in its success. Let me recount a case or two:—(1) A girl, æt. 23, had been suffering for some months from tubercular cystitis. She had failed rapidly in health, had incessant and severe pain, and was passing much pus in her urine. The pus contained enormous numbers of tubercle bacilli, every field of the microscope showing several. Her opsonic index was .6. An injection of 1/1000 mg. solid substance T.R. was given. In a few days her index had risen to 1.4, her pain had become much less, and the urine contained only a little pus. An injection of 1/500 mg. was given ten days after the first, and another a fortnight later. Under this treatment the index was found above 1.2 on the several occasions when it was estimated. Her pain entirely ceased, and the pus and tubercle bacilli disappeared from the urine. Unfortunately, the girl could not remain under treatment, and she returned to the country. I heard some twelve months later that she died of the disease. (2) A woman, æt. 35, was suffering from tubercular salpingitis and peritonitis. She was a patient of my colleague, Dr. Jellett, who opened the abdomen in January, 1906. He found the tubes so extensively diseased, and the tuberculosis so general and so advanced, that he did not remove anything, but closed the abdomen. Some weeks later he sent her to me for vaccine treatment. When I saw her in February, 1906, I thought her so ill that I was loth to attempt any treatment. She was emaciated in the extreme, very weak, and very ill. An injection of 1/1000 mg. was given, and followed in a fortnight by one of 1/500. She remained under treatment until November, getting injections at first every fortnight, and afterwards, owing to her living in the country, every month. In October neither Dr. Jellett nor I could find any trace of disease, and she professed herself in perfect health. She had increased in weight by two stone and a-half. Her health was so good that she ceased treatment and got married.

In other cases one sees remarkable improvement in scrofulous glands, in tuberculosis of bones and joints. Of one instance of the latter I will recall the main features. A young girl, æt. 15, developed signs of

tuberculosis of the knee-joint. She was put to bed, and given injections of tuberculin. After two months' treatment a small piece of dead bone the size of a pea was extruded. The aperture speedily healed up, and in another two months the girl had completely recovered. She has now remained well for two years.

In what I have said I have endeavoured to make clear to you that in vaccine treatment we have a method easily applied, requiring no special skill beyond what experience and careful observation can give any medical man, a safe method, and one fraught with great possibilities in many varieties of infective conditions. I have avoided mention of conditions whose treatment requires special bacteriological skill other than what can be easily obtained, and in particular I have not advised the estimation of the opsonic index. I believe that the estimation of the opsonic index is a considerable aid both in diagnosis and treatment, but I have tried to show that much good may be done without reliance on it, in the treatment of many infective conditions.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by F. J. Smith, M.D., Physician, London Hospital. Subject: "The Examination of the Person."

## BRADSHAW LECTURE.

### DARWINISM AND MEDICINE. (a)

By JAMES ALEXANDER LINDSAY, M.A., M.D.,  
F.R.C.P.,

Professor of Medicine in the Queen's University of Belfast, Physician to the Royal Victoria Hospital, Belfast.

#### PART II.

*Darwinism and Disease.*—What light can evolution throw upon disease, upon its origin and course, upon the response of the organism to its assault, upon immunity and proclivity, upon the principles and results of treatment? On all these heads something might be said, but the issues thus raised are too far-reaching to be adequately dealt with on the present occasion.

An inquiry into the origin of disease in the biological sense may well seem futile. How the first bacillus of tubercle or the first *plasmidium* of malaria came into being may be regarded as a problem as mysterious and as futile as the origin of matter or the origin of life, questions which Darwin always refused to discuss. "It is mere rubbish," he says in one of his letters, "thinking at present of the origin of life: one might as well think of the origin of matter." Yet the origin of life has provoked many speculations, inconclusive, but not absolutely vain and sterile. The origin of a morbid micro-organism can be only dimly surmised, but evolution may help us to understand how such organisms have acquired their potency for mischief. In some cases, e.g., tuberculosis, there is reason to believe that civilisation and the habits of civilised man have had much to do in conferring toxicity upon an organism comparatively innocuous under more primitive conditions of existence. Many facts of bacteriology suggest to us that organisms such as the pathogenic bacteria owe a large part of their virulence not so much, as it were, to their inherent properties as to certain conditions of growth which are only very partially known to us. If this view be sound, it will follow as an obvious corollary that tuberculosis is to be suppressed, not by destruction of the bacillus, but simply by depriving it of those conditions necessary for its growth and development.

Evolution may throw some light upon the different effects which the same ætiological factors are known to cause in different individuals. Over-indulgence in eating and drinking produces in one individual gout, in another cirrhosis of the liver, in a third renal disease, in a fourth arterio-sclerosis, and so on. How are we to

account for the different responses to the same stimulus? We have to assume some congenital peculiarity in the individual, the result of factors which may stretch back to a remote past, and which have been developed in accord with evolutionary laws. A similar train of reflection is suggested by the facts of immunity, a subject upon which so much brilliant work has been done in recent years. The precise mechanism of immunity, the action of phagocytes, alexins, or other protective agencies, need not be here dwelt upon. The effects of food, temperature, fatigue, of previous diseases, of protective inoculation whereby the specific protective substances have to be formed in the body itself, and of immunisation by transference of protective substances previously formed in antitoxic serum, are well known to you. What seems clear is that when full account has been taken of all secondary causes of immunity, we are thrown back upon a factor, which we may vaguely describe as "constitutional" or "congenital," or as a personal peculiarity or idiosyncrasy. Why does one individual fall a ready prey to scarlatina or diphtheria, while another resists repeated exposure to contagion? It is of great interest to learn that certain protective agencies are at work, which can be, to a certain extent, recognised. But it is clear that the recognition of such agencies only pushes the problem farther back, and does not finally solve it. That the predisposition to contract infective disease, or to resist infection, runs strongly in families is a matter of daily observation. Some people, as the saying is, "catch everything that is going," others escape though equally exposed to infection, and these peculiarities are found to characterise certain stocks and strains. Again, some persons on being infected, quickly develop all the usual consequences of infection, while others develop them slowly, or imperfectly, or even not at all. We are familiar with the fact that the bacillus of diphtheria may be present in the fauces of healthy individuals who have been in close contact with sufferers from the disease, and no further development occur. It is probable that most of us at some time or other have received the bacillus of typhoid fever into our systems, in most cases without injurious result. I may even suggest to you that some persons have tubercle bacilli in their sputum and seem very little the worse for their presence. These facts might be multiplied indefinitely, and they all point in one direction, viz., that when all the secondary agencies of immunity have been unveiled—and the inquiry into them is one of extraordinary interest and importance—we shall still be left with some unexplained factor, some congenital or hereditary element which has arisen in accord with evolutionary law. We have facts which suggest to us that civilised nations are undergoing a process of gradual immunisation to infective disease. When measles was first introduced into the Faroe Islands and the Fiji Islands, there was an enormous mortality, amounting in some cases to one quarter of the entire population, while subsequent epidemics have shown a much lessened virulence. In accounting for such facts there seem to be two possible theories:—(1) That certain inhabitants of these islands possessed a special susceptibility to the toxin of measles, or (2) that the population as a whole in some way developed an acquired immunity, of course to an incomplete extent, against the disease. The extraordinary virulence of Asiatic cholera when it first penetrated from its original home in Bengal to Europe and America is a phenomenon of the same category, while its declining severity in subsequent invasions, which is so often attributed solely to improved hygiene and greater caution regarding food and water, may really be due in part to the operation of an evolutionary law. Why are negroes so resistant to yellow fever, so susceptible to tuberculosis and small-pox? May it not be that the explanation is evolutionary, that the negro has been longer in contact with the first mentioned disease than with the remaining two, and has hence acquired a certain degree of immunity against it? Why are Anglo-Saxons in India so much more susceptible to typhoid fever than the native inhabitants? Is it because the latter, inhabiting a country where hygienic laws are so little recognised,

(a) Delivered at the Royal College of Physicians, London, on November 2nd, 1909.

have developed a considerable degree of immunity? Or, is it, as some affirm, that a large proportion of the native inhabitants suffer from mild attacks of typhoid fever in youth and hence are protected during the rest of their lives? Tuberculosis is rapidly declining amongst nearly all civilised nations. Is this exclusively the result of improved hygiene, a higher range of comfort, better houses, better food, or is it in part the effect of a gradually developing immunity? Further, it may be asked—Are the two views really incompatible one with the other? How far is an acquired immunity due to improved methods of living? Again, we may ask—Is the growing sobriety of civilised nations the result of a gradually developing immunity against the injurious effects of alcohol? Are the drunkard and the intemperate undergoing a process of slow but sure elimination?

My object is not to affirm any dogmatic opinion on these important issues, but to suggest to you that in our thinking on these matters we must take a wide and philosophic view; we must recognise that in disease great secular processes, as well as more concrete causal factors, come into view. The present generation of medical workers and observers is somewhat impatient of those conceptions of "diathesis" and "temperament," which meant so much to our predecessors. We are disposed to think that these ideas lack definiteness and concreteness, that they are too vague to be any of real utility. Yet a study of evolution in its bearing upon disease may suggest to us that these terms, vague though they are, adumbrate a great truth—viz., that in proclivity to infection and response to disease, nothing is so potent as what we vaguely call "constitution," "temperament," "hereditary tendency," and the like. We have been intent upon the "search for the microbe," a search which has already yielded brilliant results, and it is needless to say, must be continued. But the response of the organism is an element at least as important as the presence of the toxin. In the future, it may turn out that we shall be compelled to devote less attention to the seed, more attention to the soil.

Evolution is capable of throwing a flood of light upon many of the most familiar phenomena of disease. We are apt to accept these phenomena as ultimate facts, as the effects of a toxæmia or of some other obvious causal factor. But it is possible to push the analysis a little deeper, to trace the true inwardness of morbid phenomena a little farther back. Let us ask the question, How does it happen that in an ordinary case of hemiplegia the arm suffers more than the leg or the face, and in the arm, why is it the finer movements of the fingers and hand which suffer more than the coarser movements of the elbow and shoulder? It is easy to answer that the reason is anatomical and relates to the seat of injury and the distribution of fibres in the Internal Capsule, but this explanation needs itself to be explained. Here, again, we may without extravagance invoke evolutionary law to help us. The fine manipulations of the hand and fingers are in all probability the last to be acquired by the developing organism, they are the least stable acquisitions of nervous tissue, they are the first to suffer under the shock of disease. The nervous system, as it were, most easily forgets the lesson most recently learnt, just as the old man forgets the events of yesterday while he remembers those of fifty years ago. Aptitudes recently acquired in the genetic series are less ingrained, as it were, in the nervous system than those which go back to an earlier stage of development. Dr. Hughlings Jackson long ago pointed out the order of the dissolution of function in the brain when under the influence of alcohol. The first to go are the highest faculties, judgment, memory, taste. In the next stage speech becomes affected; it becomes thick and indistinct. Next the emotions are involved, the individual becomes hilarious, maudlin, or quarrelsome. Last of all, the centres of organic life, respiration, circulation, deglutition, are affected, and death may ensue. Now, this order of events is not fortuitous. The nervous functions, under the influence of a narcotic poison, undergo dissolution in a definite order, the order of develop-

ment, which corresponds to the order of complexity and specialisation. It is probable that this law will be found to have a somewhat wide application in the field of disease. General paralysis of the insane is a good case in point, the elements of character and judgment usually suffering before those of voluntary movement.

That the laws of evolution and the influence of heredity throw light on the response of the organism to disease will, I think, be generally admitted. We are not wrong in attaching weight in prognosis to any known family tendency in connection with any given case of disease. It helps us in forming some estimate of that subtle and intangible, but most potent element, what we vaguely call "the resisting power of the individual." In many cases of disease we give the first place in prognosis to what is termed "the observed tendency of the individual case." This is not a truism, though it may sound like one. Let me take an illustration. A patient presents himself with the signs and symptoms of slight incipient tubercular infiltration of one apex, and the question of prognosis arises. We know that the disease may either undergo early and complete arrest, or develop to a certain extent and then undergo regressive fibrotic change, or progress to softening and excavation, or become rapidly disseminated throughout the pulmonary area. It is quite out of our power to predict with certainty which of these events will happen, but in attempting any forecast nothing is more helpful than attention to family history on the one hand, and, on the other hand, to "the observed tendency of the individual case," which time alone can reveal. We are dealing with the power of resistance which the individual can offer to the action of the tubercular toxins, and that power is part and parcel of the individual's heredity and "constitution"—it is developmental and evolutionary.

It has been debated whether there is any such force as a "*vis medicatrix nature*." Many have regarded the existence of this force as obviously written on the face of Nature, while others have denied even its existence. Can evolution throw any light on this question? Nothing can be more certain than that Nature tends to revert to the normal. In another connection Francis Galton calls this "the law of regression towards mediocrity," in other words, the tendency is for the abnormal to disappear and for the unity of type to be preserved. Darwin thought that this law had a wide application, and was even inclined to believe that tall men often married short women, and that clever men often married silly women—Nature's unconscious protest against the abnormal and unconscious striving to preserve the unity of type. If such a law exists, we might argue without paradox that disease is the abnormal, and that on the broad grounds of evolutionary law we might expect the tendency to be to eliminate the abnormal and to return to the normal. That tendency may, of course, be too weak successfully to resist the forces in opposition to it.

*Darwinism and Race Problems.*—Let us now turn to a field where by general consent the influence of evolution has been potent. The "Survival of the Fittest"—a term first suggested by Herbert Spencer—and its correlative, the "Elimination of the Unfit," have been generally accepted as expressions which succinctly sum up the effects of the operation of Natural Selection. It is important to remember that "fittest" does not mean best, either physically or ethically. It simply means fittest for the conditions of existence in any given case, most fully adapted to the environment, best able to succeed in the struggle for existence. Evolution does not necessarily involve progress, though the general law is progression from the lower to the higher, from the less to the more specialised. "Everything depends upon adaptation," says Weismann, and Höfding reminds us that "adaptation and progress are not the same." Degeneration is as truly evolutionary as progress, the upward and the downward movement being both the result of adaptation. Further, evolution does not postulate that organs and organisms are perfectly adapted to their present

needs and conditions. They may be in process of becoming perfectly adapted. Natural Selection, Darwin reminds us, tends only to make each organic being as perfect as, or slightly more perfect than, the other inhabitants of the same area, with which it comes into competition. When competition ceases, natural selection ceases. "Natural Selection," says Hugo de Vries, "acts as a sieve; it does not single out the best variations, but it simply destroys the larger number of those which are, from some cause or other, unfit for their present environment. In this way it keeps the strains up to the required standard, and in special circumstances may even improve them." The conditions of racial efficiency as defined by the laws of evolution would seem to be the following:—

(a) The race must become progressively adapted to its environment, and by environment we mean climate, food supply, and competition in the struggle for existence.

(b) There must be competition and struggle, leading to elimination of the unfit, otherwise degeneration will take place.

(c) There must not be too much inbreeding, and each strain must be from time to time crossed by another and allied strain. To this last law there are, however, some curious exceptions.

When we compare man with the lower animals in these regards, we are at once struck with some obvious points of contrast. Man is not subject to the unrestrained operation of natural selection. He wears clothes and builds houses to protect himself from the storm and the cold. He brings food from farthest East or remotest West to make up for the deficiencies of the home supply, and he lays up stores against the day of famine. He protects the reproductive function by law and custom. He restrains the warlike instinct and keeps it within bounds. He prevents or cures disease, makes life possible for the feeble, the ailing, and the malformed, and even gives them the opportunity of propagating their kind. He cherishes the aged and enables them to prolong their days. By some of his laws—*e.g.*, the law of primogeniture—he sets the principle of natural selection at defiance. In these and other ways the ordinary usages of civilised society run counter to the operation of natural law, and it becomes an anxious question whether civilisation, in so doing, does, or does not, contain the seeds of its own dissolution. Rousseau and his school believed that civilisation involved degeneration. Evolution was not within the purview of their thought, but we cannot evade the issue: Does evolution strengthen the contention which these thinkers reached by a process of intuition, whether true or false? We hear much to-day of the degeneracy of the nation, and the existence of such degeneracy is assumed by many writers. The question is, however, one of extreme complexity. It is almost impossible to obtain the data for a just comparison as regards physical fitness between the present and preceding ages. On the one hand, the ratio of defectives, including deaf and dumb, lunatics, epileptics, paralytics, infirm, etc., is said to have increased from 5.4 per 1,000 over 15 years in 1874 to 11.6 in 1896. On the other hand, there are some encouraging facts. The average duration of life is increasing. Some of the worst scourges of the human race—tuberculosis, typhoid fever, malaria—are abating their severity; the sick-rate of our benefit societies is declining. But these facts are not irreconcilable with the possibility of physical degeneracy. In the absence of conclusive data on this crucial question we may ask whether any light is obtainable from the study of evolutionary law. Are there any analogies from plant or animal which may contain suggestion for us? Domestication amongst plants and animals is the analogue of civilisation amongst men. The effects of domestication are, however, exceedingly complex. In some animals—*e.g.*, the bear family and carnivorous birds—domestication leads to sterility; in others—*e.g.*, sheep, pigs, and barn-door fowl—domestication seems to increase fertility. Many flowers become double under cultivation and continue fertile, while other double flowers lose the power of producing seed. Some highly-bred

animals develop a marked delicacy of constitution, and become very liable to disease. In some plants an artificial increase in the richness of the soil tends to the production of wood fibre rather than of flower and seed. On the whole, the above facts do not help us. The main question remains: Does civilisation, by preserving the unfit and preventing their ruthless elimination which takes place in a state of Nature, imperil the physical integrity of the race? Our marriage customs, for example—the not uncommon conjunction of youth and beauty with age and wealth, the transmission of enfeebled constitutions, and sometimes of actual disease, from parent to child—can such things be tolerated without grave risk to the physical welfare of humanity? Is the medical profession free from serious responsibility when it preserves those whom Nature has plainly marked out for elimination, and even enables them to transmit their unfitness to their descendants? These are not extravagant or sentimental questions. They are, on the contrary, highly practical questions, and if we so often keep them out of sight, I suspect it is from an uneasy sub-consciousness that they involve painful and paralysing issues.

That civilisation runs counter to natural selection is, I think, evident. It interposes artificial barriers to the free play of those forces which in a state of Nature give the victory, both as regards personal existence and opportunity for perpetuating the species, to the strong, the brave, the fit. But it is not to be assumed without argument that civilisation is dependent upon natural selection. According to Lloyd Morgan, "natural selection has long ceased to be the dominant factor in human progress." The same view is propounded by J. B. Bury in the following passage:—"It may be said that, so far as concerns the actions and movements of men who are the subject of recorded history, physical environment has ceased to act mechanically, and, in order to effect their actions, must affect their wills first, and that this psychical character of the causal relations substantially alters the problem. . . . Most thinkers now agree that the chief clues to the growth of civilisation must be sought in the psychological sphere. Imitation, for instance, is a principle which is probably more significant for the explanation of human development than natural selection." That is the view of a historian, and it must be admitted that it contains a great deal of truth, though not the whole truth. Mankind is more dependent for its progress upon the brain of a Pasteur or a Lister, a Kelvin or a Marconi, than upon the muscles of many cricketers, footballers, or oarsmen. The puny, sickly, or deformed child, which in a state of Nature would be promptly eliminated, may possess the brain of a great discoverer, poet, or statesman. Yet physical soundness can never be ignored or deemed of small significance. If physical degeneration is going on in our midst—and who can deny the fact, however much we may differ as to the extent of the fact?—we may feel sure that it is due to some species of non-adaptation to the environment. We are inclined to attribute such degeneration as exists mainly to unwholesome surroundings, bad housing, bad air, bad food, insufficient exercise, unsuitable clothing. These factors have weight—perhaps much weight—but a study of the phenomena of evolution may well make us doubt whether they are really the heart of the problem—whether, after all, the main thing is not that we are, to a more or less extent, breeding from the wrong stock. Few men have had less reason than Darwin to retract any opinion once definitely formulated; few have been from first to last more consistent in their views; but it is clear that Darwin wavered much and wavered often as regards the weight to be assigned to external conditions, climate, food, occupation, as factors of evolution. He was at one time inclined to attribute very little weight to such conditions in comparison with natural selection; later in life he was disposed to assign greater importance to them. Some of his followers have regarded these factors as insignificant. The point is one on which I shall not attempt to pronounce, but I shall content myself with

the contention that race degeneracy, where it exists, is not to be satisfactorily explained by the operation of temporary and transitory causes, but must be sought in the most profound laws of growth and survival. Let us look at another racial problem in the light of evolutionary law—viz., infant mortality, which we are all agreed is excessive. Is infant mortality due simply to bad hygiene, unsuitable food, careless mothering, or is it in any sense the analogue of the terrific waste which we know to go on in Nature? Stand under one of our forest trees and watch the clouds of pollen which fall around. How many of these granules ever reach an ovule? In a well-known passage Tennyson tells us of the sad misgivings which the spectacle of the portentous waste in Nature excited in his breast:—

"Are God and Nature then at strife,  
That Nature lends such evil dreams?  
So careful of the type she seems,  
So careless of the single life;

"That I, considering everywhere  
Her secret meaning in her deeds,  
And finding that of fifty seeds  
She often brings but one to bear,

"I falter where I firmly trod—"

Tennyson understates the case. Nature exhibits an amazing, a sinister prodigality of increase and of destruction. A single flesh-fly, Wallace informs us, produces 20,000 larvæ, which reach their full size in five days, so that each parent fly may be increased ten-thousand-fold in a fortnight. A pair of our common birds—thrush, blackbird, sparrow, titmouse—if allowed to live and breed unmolested, would have in ten years no less than twenty millions of descendants. The machinery of destruction is, however, in a state of Nature not less efficient than the machinery of growth and increase. It is a somewhat melancholy reflection that a similar law is at work amongst mankind. We may recognise this law without proposing to acquiesce in it. In this instance, as in others, we shall find that civilisation and natural selection run counter to each other. As civilisation advances the birth-rate falls. This is, apparently, a universal law, complicated though it may be by local conditions or national habits. The birth-rate is steadily falling amongst our own nation, and even more decidedly in France and America. In the former the fall has been sufficient practically to arrest the natural increase of population. A phenomenon of this kind, apparently world-wide in its operation, and one that could not have been anticipated, must depend upon evolutionary law. Herbert Spencer is inclined to think that intellectual development and the reproductive faculty have to a certain extent an inverse ratio to each other, and that the rapid increase of the population of the world—"even slow-breeding man," Darwin tells us, "has doubled in twenty-five years"—will be arrested as civilisation develops. I cannot detain you with any of the ethical problems which such a view suggests. I must content myself with pointing out how evolution seems to be operating, how profound is its influence, and how mistaken we shall probably be if we attribute such large facts as a falling birth-rate solely to temporary and wholly preventable causes.

The relation of the medical profession to the question of the propagation and preservation of the unfit raises many difficult questions, which cannot be adequately considered on this occasion. The question of our responsibility to those who shall come after us, though not a new ethical problem—it is found in Plato—has become a practical question only in modern times. It is a principle with which we have henceforth to reckon. The art of medicine was for thousands of years concerned solely with the cure or relief of disease. At the present day the prevention of disease bulks hardly less largely in our thought, and this point of view indicates a distinct advance. In the future one may predict with confidence that the preservation of the purity of the race will be regarded as one of the essential tasks of the art of medicine. The whole

question, it is almost needless to say, is involved in the greatest difficulty, but it will certainly force itself increasingly upon our attention. It will do so with the greater insistence if we realise that the future physical well-being of the race will be determined more by natural selection than by attention to environment, important though this latter factor may be. That the medical profession will ever in this country be invested with disciplinary powers for the regulation of marriage seems doubtful. Such control would probably be foreign to the habits of mind of the British race, but we see that attempts have been made in this direction in some of the States of the American Union, and to a lesser extent in Germany, with what degree of success I am unable to say. It seems probable that in this country we shall have to rely upon the operation of an enlightened public opinion—enlightened, as it must be, to a large extent, by the influence of the medical profession.

Is the human form destined to undergo important changes in the future under the operation of evolutionary law? Are we to look for the coming of the Super-man, a conception with which the thought of Nietzsche has rendered us familiar. "What with man is the ape?" says Zarathustra. "A joke or a sore shame. Man shall be the same for Beyond-man—a joke or a sore shame." This is by no means certain. Weismann thinks it doubtful whether man may not have achieved the summit of his development, both as regards physique and intellect, and is inclined to look for progress solely in the ethical sphere. Yet some of the facts adduced in this address seem to point decisively to the conclusion that the human body is destined in the course of many generations to undergo at least minor changes. The teeth, the hairy covering of portions of the body, the toes, the special senses, are almost certain to undergo modification. Nor can we limit the probability of change to such parts as these. All we can say in this connection is that the changes which will come will be the outcome of evolutionary law. Useless organs will be eliminated. Useful organs will undergo progressive adaptation to altered conditions—such as diet, climate, habit, occupation. The possibility of reversion and of degeneration will always need to be reckoned with.

A general survey of the relations of Darwinism to the science and art of medicine is likely, I think, in many ways to be salutary. It will certainly tend to breadth of view, to a philosophic appraisement of the factors with which we have to deal, to a recognition of the great underlying laws and secular processes which are related to our art. It may, perhaps, act as a damper upon enthusiasm when we realise that evolutionary change is slow and only partially under our control, but, if this be the truth, it is better for us to know and recognise it. Medicine will gain in stability and in influence, as well as in dignity, by being in close relation with the higher thought of the day. It may, in some not unimportant particulars, react upon that thought. Disease becomes something more than a disagreeable and embarrassing fact when we realise how closely it is related to evolutionary processes, how vivid is the light it is capable of throwing upon evolutionary law. It even takes its place—a temporary place, we may hope—in the eternal order. "Harmonious order," says Huxley, "governing eternally continuous progress; the web and woof of matter and force interweaving by slow degrees, without a broken thread, the veil which lies between us and the infinite—that universe which alone we know or can know—such is the picture which science draws of the world."

THE widow of the late Herr George Speyer, of the Speyer banking house, who died in Frankfurt-on-Main a few days ago, has left from eight to ten million marks to charities. Large sums are also left for the study of lupus and cancer, to Jewish charities and hospitals, and to the pension funds of the Speyer branches in London and New York. The will further provides for contributions to the auxiliary funds for theatre, chorus, and orchestra employees, and the Journalists' and Writers' Association.

## ORIGINAL PAPERS.

THE STUDY AND TREATMENT OF  
ACUTE PERITONITIS. (a)

BY PROFESSOR FEDERMANN, M.D.,

Of Berlin.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

GENTLEMEN,—In but few affections does the fate of the patient depend so much on speedy recognition on the part of the medical man who is first called in to the case, as acute peritonitis. To him who recognises the danger and presses for an operation is the patient more indebted for his life in case of recovery than to the surgeon who performs the operation. Although we have achieved much in combating this disease, only a few years ago so fatal, a great deal remains still to be done. Even to-day numbers of people die of peritonitis, the greater part of whom would be saved if their condition were recognised in time. If I permit myself to discuss some general important points arising under the head of acute peritonitis before this audience, I do it the more willingly as I have had the opportunity during long years of making many valuable personal observations on the subject in the copious clinical material of the Moabit Hospital in this district.

The greatest advance in the domain of acute peritonitis is in the knowledge gained that it is a disease curable by operation, and that the chances of success are the greater the earlier the operation is performed.

It is only in the rarest cases, in which a very virulent poisonous material rapidly floods the system, as happens most frequently in the perforating form, that the earliest operation comes too late. Here death takes place so rapidly, often in a few hours, that the local peritoneal reaction is either absent altogether, or it leads at most to a totally insufficient sanguineo-serous exudation. The general poisoning of the system is the most pronounced of the symptoms in this class. Apart from these exceptions, however, even in cases of severe perforative peritonitis, by early operation we are able to become masters of the poison. The earlier the operation takes place the more simple it is, the less harmful, and the better the prognosis.

Our endeavours to reduce the mortality of peritonitis must be directed rather to refining our special diagnosis than to elaborating a *technique* of operation. It must be our aim to be able to judge of the condition of our patient, and especially in the early stages, with sufficient certainty to lay down a plan of treatment. I believe we are in a position to do this after 20 years of abdominal surgery, which first gave us any knowledge of the origin and course of peritonitis, whilst before that, when we only saw the disease in its later stages or in the dead-house, our knowledge was very imperfect and sometimes misleading.

## PATHOLOGICAL ANATOMY.

Although as a rule there is no parallelism between the clinical features of peritonitis and the pathologico-anatomical changes, a correct estimate of the extremely many-visaged group of symptoms is only possible when we have a knowledge of the pathologico-anatomical basis. It is only when at every stage of the disease we have before our eyes its anatomical features as they are, and as they may be by possible development, that we reach a standpoint for therapeutical measures. I would, therefore, throw out some preliminary observations, important for forming a judgment of the disease, on the mode of origin, basing them principally on my experiences in appendicular, gonorrhœal, peritonitis, and that arising from perforated ulcer of the stomach.

A grouping of the various forms of peritonitis is possible and appropriate, as they all show a course that is fundamentally uniform with only gradual variations.

Every purulent peritonitis is at bottom of bacterial origin, and is an infective disease. As with all infective diseases, the degree of inflammation depends on

the one hand on the intensity of the infection, and on the other on the resisting power of the organism. The product of the mutual action of these two components is shown in inflammations of the peritoneum in the form of the limitation that the exudation meets with as regards the other parts of the abdominal cavity. We have, therefore, arrived at the point of looking at the presence and kind of limitation as the anatomical expression of the severity of a peritonitis, and as a basis of distinction. On this basis we distinguish two groups of peritonitis, that which limits itself and that which progresses, and in this division we bring to the front the factors that are of the greatest importance in judging of the disease. All other divisions, such as diffuse and general, are to be rejected as misleading and illogical. Also between the types as distinguished above there is by no means any basal differences, but only such as are of a gradual nature and often passing into each other.

The origin of both is fundamentally mostly the same.

If infectious material passes into the abdominal cavity through a perforation or along a lymph tract, an exudation follows as a reaction of the serosa; this varies in its extent as well as character according to the virulence. At the commencement the exudation is always clear-serous; it becomes cloudy, however, by destruction of bacteria and accession of leucocytes, the more quickly and the more intensively the graver the infection is, it becomes purulent or sanious. At the same time, the more intense the infection the more it suffers loss in fibrine, and with it its plastic potentiality. Early operations have brought to light an important fact, having shown that in the first 24-48 hours the exudation in the great majority of cases is free (diffuse), lying between the intestines. It is only secondarily by deposition of fibrine that adhesions and limitations are formed that put a stop to the extension of the inflammation, and make a limited peritonitis out of one hitherto free; a so-called intra-peritoneal abscess thus forms, which through perityphlitis is well known to you all. Whether the first free peritonitis will pass into a circumscribed one cannot be predicted with certainty in the majority of cases during the first 24 hours, as both forms at this stage present the same anatomical and clinical features. I shall describe later what therapeutical consequences we must draw from this fact. The genesis of circumscribed peritonitis out of a diffuse one is certain as regards three-fourths of all abscesses, whilst I should only assume their occurrence from infection in an already closed space, according to the old views in one-fourth of the cases. The above-named genesis explains without difficulty the manifold localisation, as even a diffuse inflammation that has already attacked the greater part of the abdomen, may become localised in various places. There are certain places of predilection, however, of which the most important are the pouch of Douglas, the sub-phrenic space, and the lateral regions of the lower abdomen. The abscess is always more limited as to space than the diffuse inflammation has been, and it not infrequently happens that a peritonitis spread over the whole of the lower abdomen contracts to an abscess the size of an apple. The further course the abscess may take—complete absorption or further growth—I do not go into now.

Although the organism in every case of peritonitis has a tendency to circumscribe by deposition of fibrine and thus bring the process to a standstill, as we can see by the presence of adhesions in the rapidly advancing forms of peritonitis, success in achieving the limitation is only attained in a part, in the less virulent cases. In the remainder the disease progresses equally to more or less numerous and firm adhesions, but as a whole it still goes on, either because the infection has been too intensive from the first, or because exacerbations have taken place, and finally leads to death, unless removal of the original focus is effected. Between the intra-peritoneal abscess and the perfectly uncircumscribed free peritonitis, there are numberless transitions. It is both practically and theoretically not worth while to give special names

(a) An Address delivered before the Charlottenburger Aerzterverein.

to the various appearances that progressive peritonitis shows, and which depend on the severity of the infection and the duration of its existence.

There is still the less need for this, as on the one hand a pure type is rarely met with, and one form runs into another, and on the other the divisions mostly come from the post-mortem table. I would only distinguish two groups in peritonitis, the exudative and the dry; the latter representing the worst form of all, and forming to a certain extent the terminal link in the chain of intensity of peritonitis. Here we reach either none or only a slight sero-sanguineous serum, the organism succumbing before the peritoneum has found time to act. The inflammation runs its course under the guise of a general intoxication, whence its name—peritoneal sepsis. To this category belong the greatest number of post-operative peritonitides.

#### SYMPTOMATOLOGY.

Gentlemen, after these few observations I need not say how indispensable it is to have decided anatomical ideas for the correct estimation of all the varied symptoms of peritonitis. And it is just in peritonitis that the observation must be made that nothing but a comparison of the symptoms present, however, is the correct estimate of the individual characters of the inflammation, and that there is no one pathognomonic sign or ever will be. Of equal importance with the comparison of the symptoms present, however, is the knowledge of the previous course, above all of the length of time it has existed, as in peritonitis—as in but few other affections—every symptom in the various stages of the disease, demands a quite different consideration. The most accurate anamnesis, that goes back not only to earlier troubles, but above all to the precise determination of the onset of the first symptoms of the disease, must be got in every case. For this is of the greatest importance as regards the indications for operation. Here I would emphasise that frequently the first violent attacks of pain are preceded by some slighter symptoms—such as nausea and uneasiness—which are very important for determining the time.

If after these general observations I pass on to a short, imperfect review of the symptomatology of peritonitis, for this I fall back on my own personal experiences, and note above all the importance of the early stage as the very first thing we do, we must get some clearness as to the time in any case before us. The difficulty of early diagnosis does not lie only in the determination of the individual character of the peritonitis, but above all in distinguishing it from other kinds of affections that have nothing whatever to do with peritonitis. It is the early operations so frequently performed during recent years, that have revealed to us the similarity of so many diseases running their course in the abdominal cavity; but in the limits of this short address I must not enter into their differential diagnosis.

After obtaining the anamnesis, the general symptoms deserve careful attention, even if an estimation of them in the early stages, on account of the very changing reactive expressions, is especially difficult. Many times a glance of the physician experienced in these diseases, at the restless expression of the patient will be enough to permit of a diagnosis, wherein, however, I do not have the *facies Hippocratica* in my mind, for that is not an early symptom. A valuable sign of grave infection—although perhaps only noticeable in the sclerotic—is jaundice. One need not expect the dry tongue; that is often enough absent in the early stage. The general restlessness that patients with acute peritonitis show even in the early stage is significant.

The behaviour of the pulse, the temperature, and the leucocytes must be looked on as the most important general symptoms.

Even in the first 24 hours of a progredient peritonitis a heightened pulse is usual; at the same time, however, plenty of cases of free peritonitis run a course for days with a slow, strong pulse, and a normal pulse rate, as well as a low temperature, need not be looked on as proof that a diffuse peritonitis is not present in any given case. The scarcely perceptible galloping pulse,

especially in association with sub-normal temperature (the ill-omened crossing curve), is a late symptom and of the worst significance.

Of lesser value than the pulse is the temperature, although it may be useful, especially as regards the differential diagnosis of non-inflammatory diseases. But it is to be observed, however, that the temperature is always raised at the commencement of a peritonitis even if, in many cases, only slightly. The fever sinks the more rapidly the worse the infection is, and those cases of sub-normal temperature in grave peritonitis belong most of all to the later stage, when a low temperature is the rule. Frequently a peritonitis is ushered in with a rigor, which is repeated with exacerbations; otherwise, however, the height of the initial fever does not presage much as to the severity of the infection.

The last and perhaps the most important of the general symptoms, and at the same time the most valuable prognostic sign is the condition of the leucocytes. It happened to me first to determine a certain regular course of leucocytosis in acute peritonitis (*Chirurgencongress*, 1903. *Grenzgeb. f. Medizin u. Chirurgie*. Bd., 12, 1903. *Festschrift f. Orth*, 1902). Hundreds of cases that have been examined have confirmed this. In my opinion apparent irregularities cannot alter the value of this symptom, for the cause of them does not lie in the method, but in the variability of the disease lying at the bottom of them. Every diffuse peritonitis sets in with a high leucocytosis over 20,000, which remains at this height or rises even higher so long as the resisting power of the organism is good, but sinks the more rapidly the more the general intoxication comes to the front. Thus under certain circumstances in perforation of the stomach a subnormal number of leucocytes of 6,000 may be observed after only 20 hours. A high leucocytosis is always, therefore, a sign of a grave infection, but at the same time is to be looked upon as a favourable prognostic sign, whilst a low leucocytosis with severe clinical symptoms almost allows of a lethal prognosis. As non-inflammatory affections run their course without any considerable leucocytosis, this especially in the early stages forms an extremely important indication as regards differential diagnosis. I would only point out typhoid, nephrolithiasis, cholelithiasis, hysteria, etc., as running a course without any considerable increase of leucocytes. The leucocytosis should therefore never be omitted in any case of acute peritonitis, but it is demanded that its value should only be appraised in comparison with the other symptoms. The height of the leucocytosis of 20,000 is of but little value for the diagnosis, as the power of reaction is an extremely variable one. In the leucocyte reaction we recognise a distinct analogy with the rise in temperature; there is no doubt that the leucocytosis is the more delicate test, that most clearly reflects the resisting power of the organism. It is to be regretted that owing to the technical circumstantiality, up to the present, it has not in Germany met with the practical consideration it deserves. I shall return later to the great importance of counting the leucocytes, in determining the indications for treatment.

Of the local symptoms I look upon as the most important, the pain, the reflex tension of the abdominal walls, and the presence or absence of a resistance. To these is added the vomiting, which is to be looked on as a reflex from the infective material in the abdominal cavity, and is a regular symptom that comes on early. The initial vomiting may often cease, to come on again in the later stage, and amount even to fæcalulent vomiting. As a rule the vomiting is associated with constipation. At the commencement diarrhoea speaks rather against peritonitis.

The Pain. The spontaneous, as well as the pain produced by pressure, plays the greatest rôle in determining a case of peritonitis, the proof of it, however, difficult to obtain from the large doses of narcotics that are given. The perforative forms begin almost always with a very violent attack of pain—often as out of a blue sky—most frequently at the site of the perforation, whether at the caecal or gastric region,

and it is usually well localised. Its accurate determination at the commencement is of importance in diagnosing the point of onset of the peritonitis. It does happen, however, that the pain may be felt low down on the right side, for example, from the gravitation of the material poured out, which has often led to an erroneous assumption of appendicitis. The pain increases so long as the peritonitis spreads both in intensity and extent until, encapsulation taking place, it becomes localised and of less severity. The making out of the sensitive zones, due to increased sensitiveness of the parietal nerves, is of the greatest importance both as determining the extent of the inflammation, and as a guide to treatment. I would remark as regards the *technique* of the examination—to which Rotter has also drawn attention—that it is best to begin at the part farthest removed from the chief seat of the inflammation, using the whole hand gently, as it is only in this way that slight changes can be made out. But even an extensive tenderness on pressure does not exclude localisation later on. It is the rule that in the later stage, the pain ceases with the increase of the exudation. In still higher degree than the tenderness on pressure is the reflex tension of the abdominal walls—the *defense musculaire* of the French—to be looked upon as the expression of the heightened irritability of the nerves of the parietal serosa. A reflex tension alone suffices as a sign of grave peritonitis, and is of so much the more value as it appears early, even in a few hours, continues for a time, and then in consequence of paralysis of the intestines, passes on into meteorism. The presence of tension is to be looked on as a favourable sign, whilst meteorism makes the prognosis unfavourable. The abdomen is often so bony, hard, and drawn in in perforation peritonitis, that the diagnosis may be made without any further examination. In cases not quite so severe, a circumscribed contraction takes place on touching the spot, and this as the expression of a violent inflammation is an indication for immediate operation. In gonorrhœal inflammation the reflex abdominal tension is absent according to my experience, and an early diffuse meteorism is the rule, which Barth has also pointed out. The proof of a gonorrhœal ætiology is important, as this form of peritonitis is capable of spontaneous recovery, and does not require operation. Tubal abortion also, which is sometimes difficult to distinguish from appendicitis, runs its course with meteorism and without abdominal tension.

The last important local symptom is the presence of resistance, the most essential mark of distinction between a circumscribed and a progressing peritonitis. By resistance is to be understood that solid feeling that is met with on palpation, that is felt in one spot, where normally nothing of the kind should be felt. The impression of a resistance is produced by a conglomerate of hardened swollen loops of intestine around a fluid, mostly purulent, nucleus, whilst the free exudation at the commencement of a peritonitis, and even the slight adhesions of a progressing peritonitis cannot be felt as a resistance. As a rule, the proof has to be obtained by palpation, as in the abdominal cavity percussion offers too many sources of error. As, however, all abscesses are not accessible to palpation—I have, for example, subphrenic abscess in my mind—the other methods must be employed when there is any suspicion of abscess. For proof of resistance every part of the abdomen must be examined, as localisation may take place in any part of it. Above all, rectal and vaginal examinations must never be omitted, as two-thirds of all abscesses are situated in the small pelvis. A resistance is so valuable for this reason that it shows that localisation is in progress or has already taken place, and this for the moment mostly contraindicates operation. A resistance can never be made out during the first 24 hours: we may look for it at the earliest on the second day of the illness. It frequently comes much later; it happens also that localisation takes place much later, sometimes after 10 days or a fortnight. Frequent examinations are therefore indispensable.

(To be concluded.)

## THE INFLUENCE OF THE TISSUES ON DISEASE. (a)

By J. RITCHIE, M.D., F.R.C.S. EDIN.

DR. RITCHIE, the retiring President, delivered his farewell address. After referring to the work of the Society during the two years for which he had presided over its meetings, and the losses it had sustained through deaths among its corresponding, extraordinary and ordinary members, he passed to the subject which he had chosen for his farewell address—the Influence of the Tissues on Disease. He said that since it was natural to pay more attention to things which could be seen and handled than things which were more vague and intangible, it was natural that the rôle played by micro-organisms in the production of disease should bulk more largely in the minds of the profession than the part played by the soil—the tissues in which they bred. He thought, however, that the proclivity of the tissues was a not unimportant factor in the cause of certain diseases, and quoted a number of illustrative cases, such as, he said, could be paralleled in the experience of any family practitioner who had opportunities of watching families for long periods of time. They saw, for instance, certain families, the children of which never escaped any illness which was going, until, when they reached a certain age, their health seemed to improve. In other families the children remained healthy until they went to school, when they began to contract all sorts of infections, indicating a special susceptibility to infectious diseases.

He ascribed considerable importance to the health of the parents as influencing the germ plasm. A case which had forcibly impressed itself on his mind was that of a healthy woman who, however, was compelled to lead a very sedentary life, and in two successive pregnancies gave birth to infants who early succumbed to tuberculosis. On her becoming pregnant a third time she led an open-air life, and the child was healthy. In the fourth pregnancy she reverted to her former habits, and the infant became tuberculous. In illustration of the effect of the tissues on the course of phthisis, he instanced the case of a pregnant woman with such advanced changes in the lungs that the possibility of a post-mortem Cæsarean section was considered in order to save the child. The mother, however, survived labour, and forthwith the lung condition improved, and the phthisis was gradually recovered from. In connection with practical therapeutics, it was of the greatest importance to recognise any underlying diathetic tendency—gouty, rheumatic, nervous, scrofulous. He remembered a case of bronchitis in which ordinary remedies were of little avail until anti-rheumatic drugs were given. These speedily brought about recovery, and the correctness of the diagnosis was verified by the patient contracting acute rheumatism and endocarditis some years later. In the same way maladies in the gouty were often unrelieved until remedies for gout were resorted to. The important thing to be realised was that we had not to treat only a disease, but a patient suffering from that disease. He then went on to discuss certain phenomena in connection with infections. In a certain number of healthy persons meningococci could be recovered from the nose, pneumococci from the mouth, Löffler's bacillus from the throat, strepto- and staphylococci from the vagina. The last-named organisms grew best in alkaline media, and the secretions of the healthy

(a) Valedictory Address delivered before the Edinburgh Medical Surgical Society, Nov. 3rd, 1909.

vagina were normally acid, hence the organism did not thrive there, and might exist along with a normal puerperium. The fact that pathogenic organisms were harboured by certain healthy persons proved that something more than their presence—namely, a weakness of the tissue defences—was needed for the production of disease. In respect of the tubercle bacillus, the most important factors in susceptibility seemed to be an hereditary proclivity, as when several members of a family residing in different parts of the world fell victims at about the same age to catarrh of the air passages, and injuries to bones and joints. He had been informed that the nomadic Arab tribes were comparatively immune from phthisis, but suffered much from osseous tubercle. This he supposed was due to the fact that though they breathed pure air, they were much exposed to blows and other accidental violence. A further point raised concerned the acquirement of a degree of immunity to infectious diseases, as illustrated by the comparison of the ravages of such a disease as measles in virgin soil with its incidence in a community in which it had been known for many generations. He explained the comparative infrequency of septic infection among parturient women delivered in the most unhealthy surroundings, amidst dirt of all kinds, by ignorant midwives, to a certain immunity they had acquired through long contact with pathogenic organisms. The relation of the nervous diathesis in influencing the course of disease was also discussed, and the part it played in producing the class of patient on which so-called Christian Science preyed. The influence of the nervous system was also seen in the susceptibility of certain patients to alcohol and opium, and, beneficially, in the favourable effect of mental rest, freedom from worry, and religious faith, on the outcome of an illness. In conclusion, Dr. Ritchie said that his object had been to direct the attention of his audience to the necessity for considering the reaction of the patient's tissues and constitution to the direct exciting causes of disease.

### FRACTURE OF THE AXIS VERTEBRA, REDUCTION, RECOVERY. (a)

By A. BRUCE, M.D., F.R.C.P., F.R.S.E., AND  
D. WALLACE, C.M.G., F.R.C.S.

AFTER showing the patient, who had completely recovered, but for some exaggeration of the deep reflexes and a very slightly spastic gait, Dr. Bruce said that he had not been able to find any record of a quite similar case. The patient was a ship's engineer, and on October 7th, 1908, as he was stooping oiling his engines, someone called his name and caused him to turn his head sharply. He was conscious of a sudden pain in his neck, and felt a lump just below the occiput. He found that he had lost the power of moving his head from side to side or antero-posteriorly, with the exception of a slight amount of forward movement. Apart from this, he had comparatively few symptoms and was able to continue his voyage. He was seen by a medical man in Helsingfors, who diagnosed the condition as rheumatism, and on his return to Edinburgh, in four weeks' time, he was seen by his own doctor, who found, in addition to the fixation of the head and a projection at the back of the neck, some evidences of pressure on the cord in the shape of pains in the arms and legs, and occipital neuralgia. He was accordingly seen by Mr. Wallace, and a series of skingrams were taken which showed that the atlas vertebra was dislocated forward, and probably that the

odontoid process was fractured. As no urgent symptoms were present, it was thought inadvisable to reduce the deformity. On March 18th, as he was sitting on a chair, one of his children snatched at a shawl which was round his neck, and gave him a sudden jerk. He again had severe pain in the neck, which was quickly followed by signs of pressure on the cord, weakness of the arms, difficulty in walking, and retention of urine. As these symptoms increased, he was sent into hospital on the 21st. On admission he was found to be a healthy man with no evidence of syphilis or other previous disease. He was completely paralysed in all four extremities, with the exception of slight power of moving the fingers of the left hand. His diaphragm was also paralysed, the abdomen falling in with inspiration, and his respirations, which were extremely shallow, were carried on almost entirely by the aid of the extraordinary muscle of respiration. His superficial reflexes (abdominal and cremasteric) were abolished; the tendon jerks of both arms and legs were exaggerated; there was a double Babinski, double ankle clonus, and a slight jaw-jerk. There was also some paræsthesia—anaesthesia over the skin of the chest, and hyperæsthesia in several regions of the body. The urine was retained and the bowels had not moved for several days. The respiration was attended with so much difficulty that the patient could only say one word at a time, and then had to draw breath. As the patient's condition was obviously extremely critical, it was decided, after explaining to him and his wife the risk of the procedure, to attempt reduction. A towel was passed under the neck over the projecting axis vertebra and was held by an assistant, while Mr. Wallace made gentle traction on the cranium. After a little manipulation the bones were felt to come into a more normal position with a slightly grating sound, and immediately thereafter the diaphragm was noticed to move freely. Respiration was soon re-established, and in the course of half an hour or so the patient had regained the power of moving his limbs. His head was kept steady between sand-bags, one being also placed under the axis vertebra so as to allow the backward drag of the head to keep the bones in position. He was then put up in a poroplastic splint so as to immobilise the head absolutely. After reduction he had an attack of congestion of the lungs lasting for a few days, but, except for that, he had steadily improved, and was now almost perfectly well, though he still wore a fixation apparatus. Dr. Bruce was of opinion that the first accident had snapped off the odontoid process, which, however, was not displaced so as to cause pressure until the second injury.

### OPERATING THEATRES.

#### PADDINGTON GREEN CHILDREN'S HOSPITAL.

DOUBLE CONGENITAL TALIPES EQUINO-VARUS.—MR. ARTHUR EDMUNDS operated on a boy, æt. 5, who had been admitted with congenital talipes equino-varus. The child had been brought to the hospital when he was a few months old, the left foot being more deformed than the right. An attempt was made to improve the deformity by manipulation and the use of a malleable splint, but without any marked success. An operation was therefore performed, the tibialis anticus, the plantar fascia, and the tendo-Achillis being divided subcutaneously, and the tibialis posticus divided through an open incision just above the internal malleolus. In the case of the right foot this was eminently successful, and after suitable splinting the foot was obtained in good position, and had remained quite satisfactory. In the left foot, however, the operation did not succeed as well; the equinus de-

(a) Paper read at the Edinburgh Medico-Chirurgical Society, Nov. 3rd, 1909.

formity was, it is true, quite overcome, but the adduction of the anterior half of the foot continued. A second tenotomy of the tendinous structures of the inside of the foot improved this slightly, and a Scarpa's shoe was then employed. This apparatus consists of a rectangular jointed splint into which the foot can be firmly strapped, the deformity being remedied by a series of screws and bands. With this apparatus the improvement which had been obtained by the second operation was maintained, and, if anything, slightly increased, but a considerable amount of deformity below the mid-tarsal joint persisted. After prolonged trial of the Scarpa's shoe, it was decided to perform an operation of a more drastic character. Two methods of treatment presented themselves: one, Phelps's operation, in which the soft structures on the inner side of the foot are divided down to the bone, the foot forced into position, and the wound, which is forced to gape by this procedure allowed to granulate or skin grafted; the second a cuneiform osteotomy. As the deformity to be remedied was one almost entirely one of adduction of the anterior half of the foot, the latter operation was the one selected, involving, as it does, no division of important nerves and vessels. An incision was made along the outer side of the foot, curving forwards from the tip of the external malleolus to just behind the base of the fifth metatarsal. The soft structures were peeled off the tarsus with a periosteum detacher, and a wedge of bone, with its base upwards and outwards, removed with a chisel, sufficient bone being taken away to bring the foot into good position. The cut surfaces of bone were secured together by a silver wire, and the wound closed. Healing by first intention followed, and when this was complete, the foot was put up in plaster in a slightly over-corrected position. Six weeks later the plaster was removed, and, with the exception of a broadening of the bases of the toes and wasting of the muscles of the leg, the foot was all that could be desired.

Mr. Edmunds said that this case shows the great difference in the difficulties met with in dealing with these cases: two deformities in the same patient differing but little in apparent severity requiring, at the hands of the same surgeon, in the one case simple tenotomies, and the other a radical bone operation.

## TRANSACTIONS OF SOCIETIES.

### ROYAL SOCIETY OF MEDICINE.

#### CLINICAL SECTION.

MEETING HELD FRIDAY, NOVEMBER 12TH, 1909.

The President, A. PEARCE GOULD, Esq., M.S., F.R.C.S., in the Chair.

THE PRESIDENT showed a  
VESICAL CALCULUS WEIGHING EIGHT OUNCES,  
which had been removed by operation.

The patient, *æt.* 71, had first come under treatment in May, 1903, suffering from an enlarged prostate. A large adenoma of the prostate was then removed by the suprapubic route, and seven small faceted uric acid stones which lay behind it. In July, 1906, a large stone, consisting of uric acid and coated with phosphates, was removed from the bladder. In October, 1909, he returned complaining of frequency of micturition, pain, and alkaline turbid urine. The sound at once struck a large stone. This was also removed suprapubically, and the man is making a good recovery. The special interest in the case was the great rapidity with which the stone formed in the bladder.

Drs. H. D. ROLLESTON and G. D. H. CARPENTER showed a case of

#### SCLERODERMA AND SCLERODACTYLY.

The patient, a woman, *æt.* 30, first felt pain and numbness in the hands, and slightly in the feet in 1895. When first seen, in 1899, she had scleroderma of the face, hands, and feet. The scleroderma had advanced in some positions and disappeared in others.

The whole of the face was affected, and the skin round the mouth was radially puckered, so that the oral aperture was much diminished. The hands were claw-like, and had been almost immobile, the terminal phalanges being atrophied and the nails very small and much curved. Attacks of local syncope and asphyxia also occurred.

Dr. T. D. SAVILL exhibited a case of

#### SCLERODERMA OF THE EXTREMITIES, ASSOCIATED WITH A PREVIOUS AND FAMILY HISTORY OF ANGIO-NEUROTIC OEDEMA.

The patient, a married woman, *æt.* 56, had had attacks of angio-neurotic oedema at intervals throughout life, and so had also her mother, and one of her two daughters. The patient's attacks ceased two-and-a-half years, when the hands and feet began to get stiff and hard. The scleroderma had extended, and grown progressively worse, and the joints had become affected. Various forms of treatment had proved ineffectual.

Dr. GALLOWAY said that he had obtained the best results by continuous and patient massage in such cases.

Dr. HERRINGHAM recorded a case, where sudden and unexpected death had occurred. He thought the condition was more than a skin disease, as it affected the muscles and deeper structures, and in this way was analogous to myositis ossificans.

Dr. H. D. ROLLESTON said that the disease was subject to spontaneous recovery, and was, therefore, difficult to ascribe to a progressive sclerosis.

Dr. T. D. SAVILL believed the condition to be due to a toxo-angio-neurosis, and said that the position of the lesion at the extremities brought it into line with Raynaud's disease. The nature of the toxin was unknown, but he thought that a more intimate knowledge of the internal secretions might lead to an explanation.

Mr. ARTHUR EVANS showed a case illustrating

#### EXCISION OF THE LARYNX, PART OF THE PHARYNX, AND UPPER END OF THE OESOPHAGUS FOR MALIGNANT DISEASE.

The patient was a female, *æt.* 40, who presented herself on September 19th, 1909, with evidence of a large malignant mass filling the lower part of the pharynx and extending forwards, so as to almost hide from view the left vocal cord. There was no glandular enlargement. The patient chose to have an operation, which was performed on October 2nd, after a preliminary gastrostomy. An apparatus had been made which fitted over the pharyngeal fistula and connected with the gastrostomy tube, and thus the patient was able to take food by the mouth.

Mr. CHARTERS SYMONDS said the condition was fairly common in women between 30 and 40. When suitable for operation, the larynx was unaffected. A colleague had removed the oesophagus in one case through the side of the neck, and made a new oesophagus devised from a flap of skin.

Dr. A. SALUSBURY MACNALT showed a case of  
THORACIC ANEURYSM IN A BOY.

The patient, *æt.* 15, showed the physical signs of double aortic disease and mitral regurgitation. Also, in front of and to the right of the trachea was an expansile tumour, over which was a marked systolic thrill. A skiagram confirmed the diagnosis. The aneurysm had increased considerably in size during the last five months.

Dr. PARKES WEBER pointed out that with every expansile movement of the aneurysm, the trachea was actually pushed up.

Dr. HERRINGHAM doubted the correctness of the diagnosis, and suggested that there was a communication between arteries and veins, and that the swelling in the neck was due to enlargement of veins.

Dr. H. D. ROLLESTON suggested that it might be an aneurysm of the ductus arteriosus.

Dr. MORLEY FLETCHER thought that congenital heart disease was present.

Dr. HALE WHITE asked if there was any evidence of congenital syphilis, as this would presumably be the cause of an aneurysm?

Dr. NORMAN DALTON thought that arterio-sclerosis

was present, as shown by the kinking forwards of the carotids, such as occurred in the condition in old people.

Dr. MACNALT, in reply, said that if an arterio-venous communication existed, he should expect a continuous murmur. There was no evidence of congenital syphilis.

Mr. T. H. OPENSHAW showed two cases of RHEUMATIC SPONDYLITIS WITH TORTICOLLIS AND SUBLUXATION.

Case 1, a boy, *æt.* 11, had a mitral systolic murmur. In 1907 he had been laid up with rheumatic fever, and again in January, 1909, when the torticollis developed. Since August 3rd, 1909, the head had been kept at rest by means of a plaster cast, and the acute pain had disappeared, whilst the rigidity was passing off.

Case 2, a boy, *æt.* 12½, had had chorea three times, and now had a mitral systolic bruit. The head was noticed to be twisted in February last. He was first seen in August last, when the pain was so acute that he could not bear the slightest touch. During the last two months he had worn a felt collar, and the pain had gone. An X-ray showed that the anterior surface of the odontoid was displaced ¼-inch from the atlas.

Mr. CHARTERS SYMONDS could remember some cases of early spinal disease with mitral murmurs, and spoke of the importance of examination of the heart in spinal cases.

Mr. T. H. OPENSHAW also showed a case of MYOPATHY—INFANTILE TYPE.

Boy, *æt.* 7½. He had never walked, and had ceased to move his legs after measles at 18 months old. Mental condition was excellent. He could not stand, even with help, and there was no sign of power in the quadriceps or glutei. Flexion of the hips and knees had occurred by contraction. Head could not be held up. The arms were markedly wasted. In August, 1909, the sartorius muscle was transplanted into the quadriceps. A portion of hamstring muscles, removed for examination, showed fatty infiltration, absence of cross striation, and irregular clefts, with granular debris, with signs of regeneration in various parts.

Mr. W. GIFFORD NASH read the notes of a case of PRIMARY HYPERPLASTIC TUBERCULOSIS OF THE STOMACH AND DUODENUM.

A woman, *æt.* 33, had suffered from gastric derangement for two-and-a-half years, and signs of pyloric obstruction for six months. Operation revealed an elongated, hard mass occupying the pyloric end of the stomach and first part of the duodenum. The stomach and omentum were covered with tubercles. Gastro-jejunostomy had relieved the symptoms, but twice afterwards the abdomen had been opened and drained of ascitic fluid. The patient died five months later. No post-mortem examination was obtainable.

Dr. H. D. ROLLESTON asked if there was any definite proof that the lesions were tuberculous, as those of new growth exactly resembled miliary tubercle sometimes?

Dr. CARNAC WILKINSON, of Sydney, said that he knew of cases where so-called miliary tubercles in the peritoneum, and even lungs, were really new growth. He had obtained very good results with tuberculin in cases of miliary tubercle of the peritoneum.

Mr. GIFFORD NASH, in reply, said he had no positive microscopic proof of the nature of the lesions.

Dr. HALE WHITE, Mr. LOCKHART MUMMERY, and Dr. H. BRUCE PORTER read a paper on a CASE OF PNEUMOCOCCAL COLITIS WITH HYPERTYREXIA; SEVERE HÆMORRHAGE TREATED BY APPENDICOSTOMY.

They thought it worthy of record for the following reasons:—

(1) It was unusual for colitis due to the pneumococcus to be diagnosed during life and confirmed by bacteriological examination.

(2) It illustrated the difficulties of such a case, and the value of treatment of hypertyrexia by cold sponging; and also the beneficial effect of iced water run through the colon for it.

(3) It showed the value of appendicostomy as a means of stopping bleeding from the colon, after the failure of other measures.

(4) The value of giving subcutaneous injections of olive oil as a means of nutrition.

Dr. NORMAN DALTON asked if the agglutination reaction had been tried to Shaga's or Flexner's bacillus?

Mr. CHARTERS SYMONDS said he had seen a case in which he thought that appendicostomy had done harm, and this opened the question as to how readily the operation ought to be employed in these cases.

Dr. HALE WHITE said that attempts had been made to obtain blood for purposes of the agglutination test, but enough was not secured. There was no question in this case but that the patient had been benefited by the appendicostomy.

# OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

MEETING HELD AT THE MEDICAL SOCIETY'S ROOMS, CHANDOS STREET, W., ON THURSDAY, NOVEMBER 11TH, 1909.

The President, Dr. G. A. BERRY, in the Chair.

Mr. SYDNEY STEPHENSON showed a case of pigment on the anterior capsule of each lens, probably representing a rare type of persistent capsulo-pupillary membrane. The President agreed with Mr. Sydney Stephenson's views.

Dr. RAYNER D. BATTEN exhibited and demonstrated an instrument for the examination of the eye under water in the erect position, and showed its application as a means of treatment. The glaucoma, for instance, after removing the instrument, the haze of the cornea disappeared. He had not had any untoward incidents with it.

Dr. DORRELL showed a case of choroidal degeneration.

Mr. W. M. BEAUMONT read a paper on oxycephaly, illustrated by a number of lantern slides. He did not agree with Patry in considering that the term syndrome should be applied to the association of oxycephaly with optic neuritis or atrophy, as the nerve involvement was a secondary result which might or might not follow. Very considerable interest had been taken in the disease in recent years since the articles by de Michel and Virchow. A number of cases had been recorded in the United Kingdom, but he thought that the credit of first pointing out the clinical symptoms of oxycephaly was due to Wm. Mackenzie, of Glasgow. His description had strangely failed to attract the attention which it deserved. This keen observer had noted the shallowness of the orbits and the consequent exophthalmos, the vertical position of the roof of the orbits, the extreme height of the head, and the blindness.

Mr. BEAUMONT drew attention to the excess of males over females; in 14 cases recorded in recent British literature there were 5 females. In Patry's list, drawn from French and German sources, there were 7 females in 64 cases. The author disagreed with Dorfmann, who advocated trephining to prevent optic atrophy, because he considered that the optic neuritis and atrophy were not due to an increase of the intracranial pressure, but rather were the result of direct injury by bony distortion. Patry had stated that Sir Walter Scott and others had suffered from a slight degree of this disease. If this were true it is possible that cases of arrested oxycephaly might be overlooked, and he threw out the suggestion that possibly sometimes so-called idiopathic optic atrophy might be due to a fruste form of oxycephaly.

Mr. BISHOP HARMAN said he had met with 6 cases in the London County Council Blind Schools, and had found the author's statement true that they were not, as a rule, mentally defective.

Mr. SYDNEY STEPHENSON recalled a case which was exhibited by Dr. James Taylor before the Society for the Study of Disease in Children, which had occipital meningocele and optic atrophy.

Mr. BISHOP HARMAN read a paper on THE MEASUREMENT OF THE DESIRE FOR BINOCULAR VISION BY MEANS OF THE DIAPHRAGM TEST.

He said individuals showed variation in the sensi-

bility of their cerebral functions. Colour and light, sense, smell, taste, and hearing all varied, and the muscle sense that maintained body balance no less. There were extremes of mental defect and striking endowment, but within the so-called average capability there was also a wide range of variation. So far the capability for binocular vision had escaped a similar critical study. Our tests either determined the presence or absence of binocular vision, or were complicated—as in the use of prisms and stereoscopes—by muscle stresses which vitiated the results.

The diaphragm test was a pure test for binocular vision, and by a variation of its mode of application it was possible to measure the desire for binocular vision as easily as the stature or weight of a man could be ascertained.

The test-cards seen through the hole in the screen of the test were viewed for their greater part by each eye separately, but a median band was seen by the direct vision of the two eyes together; this median band acted as a balancer to the eyes and their controlling mechanism; for this reason it was called the "ocular poise."

Experiments showed that different individuals, and the same individual under different conditions, required different breadths of ocular-poise, the more perfect the binocular vision the narrower the ocular-poise required to maintain the eye balance; hence the smallest measure of the ocular-poise became the measure of the desire for binocular vision.

The standard pattern diaphragm test had a fixed hole in the screen of 17 mm.; the instrument to measure the ocular-poise had a variable aperture. The aperture was varied by means of shutters which were moved by suitable gearing, the variation of the ocular-poise was shown automatically upon a scale. The scale had a compensating adjustment for the varying width between the eyes of different subjects, so that the measures given by the test became truly comparative.

Examination of binocular vision by this means showed how essentially cerebral was the controlling mechanism of the eyes, how greatly it varied in different individuals, and how profoundly it was affected by conditions of ill-health and fatigue. There seemed little doubt that on these points the test opened up many possible fields for physiological and psychological inquiry.

To the ophthalmic surgeon the new test had a particular value for those cases of occasional divergent squint with feeble convergence, which were due to defective cerebral control. These were those for which at present we had been able to do but very little. With the variable aperture to the diaphragm test the ocular-poise could be made so large as to present an attractive point of binocular fixation; and, with practice, control of the eyes might be developed, so that the balance could be maintained under conditions of gradually increasing difficulty.

Mr. N. BISHOP HARMAN read a paper on  
THE MEASUREMENT OF HYPERPHORIA BY MEANS OF THE DIAPHRAGM TEST.

If a line of letters or figures be viewed through the hole in the screen of the diaphragm test, they appeared in perfect order and alignment to the man with good binocular vision and balance. In the case of latent squint the order and alignment of the letters was altered. The line 123456789 would appear on two levels to the man with hyperphoria, in right hyperphoria, thus:—12345

56789.

The displacement was found to be constant for equal degrees of divergence, and proportionate for different degrees. So as to be able to measure the degree of divergence directly, a test-card had been prepared—one half bore a vertical tangent scale, the other a horizontal pointer. When viewed through the diaphragm test the scale was seen by one eye, the pointer by the other. When there is hyperphoria the pointer was displaced from its neutral point and appeared shifted upwards or downwards according to the kind of hyperphoria, and rested at a level of the scale corresponding to the degree of latent squint. The degree indicated was the degree required in the

correcting prism; or the same result could be obtained by measuring directly the decentralisation of any glasses worn by the patient.

The PRESIDENT discussed the paper, and Mr. HARMAN replied.

## THE WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD FRIDAY, NOVEMBER 5TH, 1909.

The President, Dr. NEVILLE WARD, in the Chair.

Dr. P. S. ABRAHAM showed a case of pemphigus vegetans in a woman, æt. 42. She had good health till ten months ago. An infant born four months ago. Nine weeks ago blebs appeared in crops with some itching. The pharynx and larynx are affected. The larynx showing bright redness without œdema. Attempts to cultivate organisms have so far failed. He also showed a case of multiple lupus, in which X-rays treatment had failed, and in which Mr. Reginald Morton was trying the solid CO<sub>2</sub> pencil. It was too early to report the result.

Mr. WALTER FRY showed a case of enlarged tibial tubercles in a boy, æt. 16. Dr. H. Robinson remarked that the disease was described as "Schlatter's Disease." Several members of the Society said it was common to find it in young people who played football, and it persisted in later life as a large bony tubercle.

Mr. BIDWELL said that he thought there was an inflamed bursa under the tendon in some cases.

Mr. D. C. FITZWILLIAMS showed a case of syphilitic periostitis of the right tibia in a boy, æt. 11. Pain was first noticed in the leg four years ago; this passed off. Six weeks ago there was pain and tenderness again. The tibia is enlarged in circumference, and the right tibia is an inch longer than the left.

Dr. E. A. SAUNDERS showed a case of syphilitic periostitis of the tibia in a girl, æt. 12. The disease in the tibia began a year and nine months ago with synovitis in the knee-joints; the tibial shafts were subsequently attacked. Both tibiae are now lengthened and thickened.

Mr. WALTER FRY showed a case of congenital scar of the upper lip in a child, æt. 2. There is a scar on the left side of the upper lip simulating the result of an operation for hare-lip. No operation has been performed. There was a deformity of the left nostril. There was a family history of hare-lip and cleft palate.

Mr. G. GRAHAM showed for Mr. C. B. Keetley a case of successful removal of a ruptured spleen. The operation was performed six hours after the accident; the spleen was badly ruptured and the abdomen full of blood. Now, fourteen weeks after the accident the patient, who is twenty-five years old, feels well, except for some shortness of breath on exertion.

Mr. CECIL H. LEAF showed a patient from whom he had successfully removed the tongue and glands of the neck. He recommended that the operation should be done in three stages:—(1) Removal of glands and tying lingual artery on one side. (2) The same operation on the other side. (3) Removal of the tongue.

Mr. Leaf also showed two patients in whom he had excised some portion of the colon containing carcinomatous growth, with end-to-end anastomosis. One patient required no purgative to make the bowels act, the other had to take an occasional laxative. He also showed a case of thyro-glossal cyst in a boy, æt. 11, on whom he had twice operated without completely curing the condition, though now only a drop or two of fluid exuded every six or seven days, and he thinks that no further treatment is indicated.

Mr. ARCHIBALD SMITH showed a woman, æt. 36, the subject of myxœdema, in whom the left forearm was 1½ inches larger in circumference than the right. The arm had diminished half-an-inch in circumference, and was much softer under thyroid treatment. There was no evidence of venous or lymphatic obstruction. He also showed a case of gumma, or epithelioma, on a leukoplakial tongue, in a female, æt. 57. No definite history of syphilis could be obtained. Microscopical report on a piece excised was doubtful. The growth

had become slightly flatter under treatment, but after hearing the opinion of the Society, he came to the conclusion that it would be better to remove the tongue at once, and not run the risk of glandular involvement. He also showed a child, aged 1 year and 10 months, with six fingers on each hand and six toes on each foot.

Mr. REGINALD MORTON said that from the radiogram he had made there was no doubt the extra fingers were supernumerary fifths.

Dr. BISHOP HARMAN showed two cases of "Coppock" cataract. The parents are not related, and do not appear to be related to any of the families which have been previously investigated, who exhibit this defect. The lenses of both parents are normal.

#### LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, NOVEMBER 4TH, 1909.

The President, Mr. T. R. BICKERTON, in the Chair.

Mr. R. W. MURRAY read a note on  
THE SURGICAL TREATMENT OF CHRONIC CONSTIPATION.

This condition, when calling for surgical interference, was met with chiefly in women who had suffered from mucous colitis. Reference was made to cases of this nature related by Mr. Arbuthnot Lane, who recommended and practised removal of the large bowel. Mr. Murray did not consider so serious a measure justifiable or necessary. Some years ago he suggested treating chronic constipation by bringing the appendix to the surface, in order that through it the large bowel might be thoroughly irrigated. Several cases were related in which this had been done with very satisfactory results.

Mr. F. T. PAUL said that he had dilated the anus in cases of uncomplicated chronic constipation, with very good result. He thought that Mr. Murray's cases were at least complicated by, if not altogether due to, colitis. He had several times used appendicostomy for this condition, and always with success. He wanted to know its value for simple intense constipation.

Dr. LLOYD ROBERTS referred to a case of mucous colitis in which, after appendicostomy, the pain caused by the lavage was so severe that the treatment could not be proceeded with.

Dr. BLAIR BELL read a paper on  
THE PITUITARY BODY, AND THE THERAPEUTIC USE OF  
THE INFUNDIBULAR EXTRACT IN SHOCK, UTERINE  
ATONY, AND INTESTINAL PARESIS.

After dealing with the work of other investigators, who had confined their attention mainly to the anatomy and development of the pituitary body, and to the physiological action of the infundibular extract upon the blood-vessels and kidney, Dr. Blair Bell described the results of his own experiments, carried out with Dr. Hick, and already published, not only upon the blood pressure, but also upon the uterus and intestines.

Further, he gave an account, with a record of illustrative cases, of the clinical use to which he had put the infundibular extract. Hitherto it had only been used occasionally as a diuretic in tabloid form. With a preparation for hypodermic administration, which had been made for him by Messrs. Burroughs Wellcome and Co., both for his experimental and clinical work, and was now on the market, he had obtained most striking results.

(1) In shock the prolonged period during which the blood pressure was raised made it a most valuable therapeutic agent.

(2) In uterine atony powerful and prolonged contractions were induced, so that in such conditions as post-partum hæmorrhage it was specially indicated.

(3) In intestinal paresis—post-operative or otherwise—immediate effects were always obtained.

Dr. Blair Bell next discussed the origin of the active principle and its probable chemical composition. He also described the method of administration of the preparation of infundibular extract for hypodermic use. Finally, the author expressed his indebtedness to his

surgical colleagues and other members of the profession in Liverpool, who had so readily tested the extract, and informed him of the results.

The paper will be published in full shortly.

Sir JAMES BARR congratulated Dr. Blair Bell on the value of his work. He thought that pituitary extract should be used with caution, and its misuse would bring it into disrepute. This drug is active in producing arterio-sclerosis, it contracts the coronary arteries, and leads to their degeneration. When used as recommended by Dr. Blair Bell, with low blood pressure, no mischief could result, and if reserved for such cases, it will hold a valuable position in therapeutics.

Dr. PENTLAND HICK, who had carried out the experimental work with Dr. Blair Bell, drew attention to the danger of using the drug in cases of heart failure.

Mr. F. T. PAUL had used it in a case of intestinal paresis after operation, with the most remarkable result, after all else had failed to give relief.

Mr. FRANK JEANS also had used the drug in several cases, and fully confirmed its action on the intestines.

Drs. A. HOPE SIMPSON and R. J. M. BUCHANAN referred to a case of splenic anæmia, with distension and ascites, in which the extract had given marked relief over a period of several weeks when given at intervals, the relief was maintained, and there was a great diminution in the size of the spleen, the fluid was kept in abeyance.

Dr. BUCHANAN also referred to the opinion held by Müller and others that the centres for the involuntary action of the uterus, bladder and rectum were situated in the pelvic sympathetic ganglia, and desired to know if the partis nervosa and intermediaris of the pituitary body could be regarded as an integral part of the sympathetic nervous system, or did the extract act by stimulating the ganglia?

He considered that those cases of so-called acute intestinal paresis associated with peritonitis, and for which operation has to be performed, are not due to any special affection of the gut itself, but to paralysis of the sympathetic nervous system, and the distension was a symptom of this condition, namely, shock.

Dr. E. E. GLYNN believed that the extract would be far less efficacious in intestinal atony due to acute general peritonitis, than to other causes.

## CORRESPONDENCE.

### FROM OUR SPECIAL CORRESPONDENTS ABROAD. FRANCE.

Paris, Nov. 14th, 1909.

#### CLINICAL ANALYSIS OF RENAL PAIN.

A PATIENT comes to consult the surgeon complaining of pain in the lumbar region. What value should be attached to the seat, the character, and the intensity of the pain in establishing a diagnosis? Such is the question that Prof. Cathelin, the eminent urologist, analysed in a recent clinical lecture.

The first thing to do in any case is to eliminate the pain common to the region. Of ten patients, fully one-half suffer from arthritism, and their sufferings are simply due to rheumatism or neuralgia, causes easily verified by absence of pain or tumour, to palpation, and also by the fact that the patients are unable, especially in the morning, to stoop down to button their shoes or pick something from the ground, while the urine is of crystal limpidity.

Satisfied on these points, the surgeon directs his attention to the kidney, where he will localise the pain and perhaps find a tumour or swelling with fluctuation. Where pain alone exists, an examination of the urine may enlighten the diagnosis. If pus is found with occasional hæmaturia and more or less cystitis, in a young patient who never had gonorrhœa, renal tuberculosis may be suspected; if no cystitis is present renal calculus may be thought of. However, here the character of the pain has its importance; it generally comes on after exertion from walking, horse, or bicycle riding. Radiography will confirm the diagnosis. Where none of the above signs are present, neither

pus, cystitis nor hæmaturia, renal cancer, hæmaturic nephritis might be suspected.

In the case of pain with a tumour, accompanied with pus in the urine, cystitis and intermittent hæmaturia, the diagnosis will probably be that of infected hydronephrosis. The absence of all those symptoms would justify the diagnosis of floating kidney. In case of hæmaturia alone, coming on at night or early in the morning, rather than during the daytime, would indicate cancer of the kidney. The cystoscope in this case would render great service.

Other renal affections, as polycystic kidney and hydatid cyst, might be mentioned, although beyond the resources of art.

To conclude, the study of pain in renal affections does not possess much real value, if its seat, character and intensity are not carefully investigated, and even then it requires to be associated with other symptoms of the important excretory apparatus of the organism. With intelligent co-ordination of all the symptoms, an almost certain diagnosis can be formulated in many of those cases which frequently escape the superficial observer.

### GERMANY.

Berlin, Nov. 14th, 1909.

At the Verein für Innere Medizin, Hr. Dietrich showed, amongst other things, a uric acid renal calculus weighing 550 gm. The patient was a woman, æt. 73, who was admitted into hospital for fracture of the neck of the femur. As she was demented at the time, no history of any kind could be obtained. On making an examination, a large, hard tumour was found in the right iliac fossa, which, after the patient's death, was found to be a calculus. It was remarkable that the kidney tissue all round the calculus was healthy both microscopically and under the microscope.

A preparation was also shown from a powerfully built man, æt. 34, who died after a few days' stay in hospital from hæmorrhage into the bowel. The autopsy showed old tuberculosis of the lungs, with recent cavities. Between the œsophagus and aorta was a cavity filled with blood clot, with rupture into both œsophagus and aorta. It was a case of tubercle of a bronchial gland that had led to spurious aneurysm of the aorta, an affection, the speaker said, that was very rarely met with.

#### THE PROGNOSIS OF ALBUMINURIA WITH SPECIAL REFERENCE TO LIFE INSURANCE

was brought before the Society by Hr. Fürbringer.

The speaker observed, as introductory, that only distinct albuminuria, as shown by the ordinary reagents, would be considered; the slight traces brought to light only by the most delicate re-agents were better left out of the question.

The first form was the so-called physiological albuminuria, with its sub-divisions into orthostatic and lordotic. Here it was not a matter of nephritic changes, but of inefficiency of the secreting tissues, often of constitutional weakness. As a rule, these albuminurias disappeared in a year or two, but they sometimes lasted longer. Many physicians held, and properly so, that the prognosis was good in these cases. He himself had watched six of them. The renal preparations of such cases were very rarely to be seen. Heubner had shown one lately. Certain slight microscopic changes were indeed present, but they could not be accepted as the cause of the albuminuria. As regarded differential diagnosis, it was to be observed that in orthostatic albuminuria there was no albumin before rising in the morning, but that it came on very quickly after getting up. Further albuminuria did not follow after administering renal stimulants, and, lastly, bodily exercise frequently had a favourable effect—a condition very different from what was met with in nephritis.

In estimating the value of the albuminuria in such cases, in his opinion proposals for life insurance with it should not be rejected, but a higher premium should be demanded. Nephritis might, indeed, make its appearance later in these cases, but the risks were not much greater than with other people that were insured.

There was also an intermittent albuminuria after infective diseases. These cases were to be considered quite favourably.

(2) Nephritis chronica levis s. superficialis. These cases were characterised by excretion of albuminous urine, with nephritic cylinders and blood corpuscles, a condition very rarely followed by anything serious. The speaker had watched a dozen such cases for years. Three of them recovered completely; the symptoms still remained in the other seven, but had led to no ill consequences. Such cases should not be rejected by the medical referee, but the premiums should be raised, and they should be only accepted conditionally.

(3) Nephritis chronica. This was an absolute bar to life insurance. The sub-acute forms were not to be rejected absolutely, but they must be put back for a time, as they sometimes recovered without a trace.

(4) Albuminuria of pregnancy. This demanded great caution, and repeated thorough examination before passing.

(5) Renal-palpatory albuminuria. As was known, albuminuria frequently appeared after palpation of the kidney, and even after palpation of the abdomen. You saved yourself from making a mistake by examining the urine before the palpation.

(6) "Sport" albuminuria. From late investigations this was shown to be always of a traumatic nature, and always ran a favourable course. It did not show any marked peculiarities as compared with the intermittent form.

(7) Acute nephritis did not generally disappear for some months. We should wait at least a year, therefore, before sending in a report in such a case.

(8) Contracted kidney. As the affection often lasts for decenniums with the system in full working order, the insurance of such patients should be rejected only when some systemic deterioration could be proved to be due to it.

Hr. Senator was of opinion that there was some kidney fault at the bottom of all albuminurias. A medical referee to a life insurance company should not be allowed to admit a case of orthostatic albuminuria with a raised premium unconditionally. Recovery might certainly take place, but it could not be absolutely reckoned on. How did the speaker define the difference between nephritis levis superficialis and benign nephritis? He himself had lately reported two cases of chronic nephritis that had died of uræmia, after 20 and 44 years respectively. The so-called benign uræmias must not be looked upon as harmless.

Hr. Fürbringer replied that he would only accept cases of orthostatic albuminuria and those suffering from benign nephritis at a higher premium after a long trial.

### AUSTRIA.

Vienna, Nov. 14th, 1909.

#### SPECIFIC TREATMENT OF RACHITIS.

ZINGER, in an original article, gives his results in the treatment of 36 cases by the new and old treatment.

Since Glisson, in 1670, first described the disease as one of childhood, though its devastating action was usually postponed till the second year of life. It was then recognised as a dyscrasia of the general organism, due to faulty hygiene in the mode of life, sometimes idiopathic, and sometimes having a secondary origin. The fact that it was a disease confined exclusively to the lower class, and more particularly arising in damp, narrow dwellings, with overcrowding, where secondary diseases would be contracted in the form of phthisis, syphilis, etc., led to the belief that a more hygienic condition would eradicate the disease. Later the digestive system was believed to be one of the primary causes; from this arose a chemical examination by Boerhaave and Switen, which has been continued to the present day by Zweifel and Kassowitz, without even yet arriving at a satisfactory explanation.

In 1842 Baginsky and Chassat commenced experiments on the feeding of young animals by excluding all forms of lime in the dietary, and thus produced rachitis according to the chemical theory of the time.

Friedleben and Tripier refuted this conclusion, and affirmed that rachitis was produced when the animals were fed on lactic acid, or when this ingredient was largely present in the food; but after much controversy it was agreed that rachitis was easily induced when the calcium was absent from the food, and a large quantity of lactic acid added, both parties claiming success. Zweifel next followed with his hypothesis of the reduction of chlorides in the blood, which checked the absorption of the calcium salts and thereby induced rachitis. These to-and-fro opinions brought Kassowitz to the conclusion that the fault lay in the absence of the phosphate of lime, one of the constituents of bone. The rational treatment followed of adding phosphorus to cod-liver oil, then iron, and finally green fruit as restoratives or prophylactic in this destructive disease.

The difficulty now begins with both young and adult in taking cod-liver oil with all these adjuncts, while green fruit is expensive and difficult to find during the winter months. To obviate this objection, "Phytin," "Visvil," "Bioson," have been put on the market with various reputed values. The latest is "Salossit," which the writer has used with wonderful success. It is composed of:—

Phosphorus anhydride, 1.17 per cent.  
Organic matter, 2.32 per cent.  
Calcium, 0.87 per cent.  
Magnesia, 0.16 per cent.  
Hygroscopic water, 0.66 per cent.  
Saccharum lactis, 94.82 per cent.

The reasonable combination of this compound induced Zingher to take an equal number of rachitics for cod-liver oil, etc., and "Salossit" treatment, therefore 18 were placed on Kassowitz's phosphorised cod-liver oil and 18 on "Salossit." From the tables given, not one suffered from gastric or digestive disturbance under the "Salossit" treatment, and the recovery was more effective and rapid, as tested by the microscopic dynamometer, and general appearance. In 6 to 8 weeks a striking improvement could be observed. With the cod-liver oil the results were good also, but of the 18, 7 of them had to have the treatment suspended on account of sickness and vomiting, with general gastric disturbances. Two of these were not able to tolerate the cod-liver oil, and had to be treated in the end with "Salossit," and improved rapidly after its commencement. It is best given in milk; a teaspoonful twice a day to a child of one year, older children three times a day. The 94 per cent. of saccharum lactis makes it an agreeable food to take, and it is easily borne by the most delicate child.

#### ADRENALIN TEST.

Zanfrognini, of Modena, has added another colour test to the number of volumetrical now in use. A solution of the brown superoxide of manganese,  $MnO_2$ , is converted into the colourless oxide, finally leaving a red-coloured solution in proportion to the amount of adrenalin present. This reaction is very sensitive, detecting one in a million. The colour is very stable after it is formed, remaining for days without change.

#### VITILIGO.

The aetiology of this obscure disease has long puzzled dermatologists, but Hesse, of Dresden, has cut the Gordian knot by telling us that fright or strong emotion both turn the hair white in a night. Why exclude the skin from the same pathological change as the hair? This is reasonable logic, but what about the facts he leaves us to infer?

#### SAUSAGE POISONING.

Hinze records the analysis of a number of cases, and points out that the incidence of the poison is most severe in the eyes. Twenty-four hours after a sausage has commenced decomposition, acute symptoms of intoxication, such as vomiting, lowered pulsation, albuminuria, constipation, anuria, and slight fever will appear, but the principal phenomena are paralysis of the ocular nerve, paresis of both oculo-motorius and abducens nerve, with paralysis and anæsthesia of the lower extremities. In severe cases encephalomyelitis disseminata toxica also appear. As most of the cases are fatal, he proposes a symptomatic treatment, stimulants, diuretics, hot baths, with injections of "Sperminum Poehl" as an antitoxin.

### EDINBURGH.

**POOR-LAW COMMISSION REPORT.**—In the Majority Report of the Poor-law Commission upon the Scottish Poor-law, which was issued on November 2nd, a number of topics of medical interest are touched upon. One of the aspects of medical relief in Scotland which seems most forcibly to have struck the Commissioners is the extent to which abuse of medical charities prevails among comparatively well-to-do persons. This abuse of hospitals, the inability of persons in moderate circumstances to obtain the advice of a specialist otherwise than by entering a voluntary hospital, and possibly also the desire of hospital authorities to procure "interesting" clinical material, have led, the Commissioners state, to the exclusion of many poor patients and cases of chronic illness. For such patients there is no provision, apart from the Poor-law hospital, to which they gravitate after being refused by the voluntary hospitals. There is no intelligent co-operation between the voluntary and the Poor-law hospitals, and no clear line, economic or medical, can be drawn between the cases dealt with in the two classes of institutions. As regards destitute and non-destitute alike, surgical and acute medical cases may be dealt with by both, though the tendency is for the voluntary hospitals to confine their attention mainly to cases of acute illness and to send chronic cases to the parish infirmaries. Compared with the voluntary hospital patient, the patient in the Poor-law hospital is at a great disadvantage. He is subjected to the stigma of pauperism, yet he or his relations may be called on to refund part or the whole of the cost of treatment, in some cases a charge of as much as 15s. a week being made. Thus, by availing themselves of the parish hospitals, patients are sometimes more independent and less pauperised than by going to medical charities. As Dr. Leslie Mackenzie put it:—"We thus have the administrative paradox that an institution intended by statute for the 'friendless, impotent, poor,' has evolved into a 'pay' hospital for poor persons. As showing the amount of gratuitous outdoor relief in the principal Scottish towns, the following particulars are given:—In Glasgow, 153,354 outdoor patients were treated during the last completed year. In Edinburgh about 88,500 patients attend the out-patient departments and dispensaries in the course of a year; in other words, taking the population for 1901, about 28 per cent. of the population receive free medical treatment. In Leith there were 12,000 consultations during 1905, and in Dundee during 1905-6, 35,097 patients were treated. Abundant evidence was laid before the Commissioners that many persons who in England would obtain medical orders are treated by medical charities, which therefore are relieving the rates to a much greater extent than is the case in England. The Commissioners regret that, notwithstanding the proverbial thriftiness of the nation, there should not exist in any town in Scotland a single provident dispensary such as are so common in England, and they deprecate the practice which has grown up unnoticed of large numbers of the community accepting charitable relief instead of adopting some provident method for themselves. They recommend that the benefit of gratuitous medical aid should be restricted to the really needy, and the adoption of some form of insurance. They do not, however, bring forward any very specific proposals, recognising that the existing state of affairs which has gradually grown up is very different to what obtains in England and Ireland, and that it is essential to introduce a new system with the co-operation of the medical profession. They therefore suggest that a departmental committee be appointed to inquire into the matter, and that some of the free dispensaries be converted into provident institutions.

**EDINBURGH ROYAL INFIRMARY.**—At their last meeting the managers appointed Mr. Henry Wade, F.R.C.S. Ed., to be assistant surgeon, and Dr. James Miller, D.Sc., M.D., to be assistant pathologist. There were six applicants for the former and three for the latter post.

**PRESENTATION TO DR. SMITH, CREETOWN.**—Dr. David Smith, who has been compelled through ill-health to relinquish his private practice and public appointments, was made the recipient, on Saturday, November 6th, of a silver salver and a handsome cheque from the inhabitants of Creetown and district. Dr. Smith has a long connection with the district, and that he is much esteemed is shown by the fact that this is the second presentation which has been made to him.

**PRESENTATION TO PROFESSOR CRUM BROWN.**—On the occasion of his retirement from the Chair of Chemistry, Professor Crum Brown was, on November 12th, presented with his portrait in the debating hall of the University Union. It had been originally intended to make the presentation an academic one, but so many of his friends outside the University were anxious to participate in it that the circle of subscribers had to be enlarged, and the actual number reached was 350. The presentation was made by Sir William Turner, who spoke as Professor Crum Brown's oldest academic colleague. The portrait is from the easel of Mr. E. A. Walton, R.S.A., and is a faithful and pleasing likeness.

**FREEDOM OF EDINBURGH FOR SIR WILLIAM TURNER.**—A circular convening a meeting of the Lord Provost's Committee has been issued, to consider a proposal which will be made from the chair to confer the freedom of the city on the Right Hon. H. H. Asquith, Prime Minister; Principal Sir William Turner; and Principal the Rev. Dr. Whyte, of the New College.

### GLASGOW.

**CLINICAL TEACHING IN GLASGOW—PROPOSED ALTERATIONS.**—The University of Glasgow have now formally committed themselves to extend the scope of clinical teaching by utilising the clinical material in other hospitals in the city other than the Western Infirmary, which is in close proximity to the University where the University students resort to at present. It is proposed to endow two professorships in the Glasgow Royal Infirmary, one of Medicine and the other of Surgery, with emoluments of £400-500 per annum. Other two chairs in Pathology and Gynaecology were contemplated, but have for the present been abandoned. It is further contemplated to render eligible for appointment as Lecturer-Examiners in the University of Glasgow the physicians and surgeons of the Royal Infirmary, and probably of the Victoria Infirmary. The selection of the candidates is to rest with the University Court and the managers of the Royal Infirmary. A second important proposal is that the number of students attending a qualifying class of clinical instruction shall not exceed a limit to be fixed by the University Court, and that the needs of women students are to be specially provided for. When these arrangements are completed students will have exceptional opportunities of studying a great variety of diseases, which at present are debarred from them on account of the great clinical material in the various hospitals of Glasgow not being utilised.

### BELFAST.

**MONAGHAN ASYLUM AND WORKHOUSE.**—At the last monthly meeting of the Monaghan and Cavan Asylum Board, the question of the present overcrowding of the Asylum was discussed. It appears that there are at present in the Asylum 504 men and 417 women, or 53 men and 75 women in excess of the legitimate numbers for their space. The Resident Medical Officer, Dr. Donaldson, warned the Board that if they tried to take in more than the proper numbers the inspectors would at once charge them with overcrowding. After considerable discussion the following resolution was passed:—"That we appeal to the Local Government Board to close up one or more workhouses in the counties of Cavan and Monaghan, with a view to provide accommodation, if advisable, for the 120 harmless lunatics now in Monaghan Asylum." It appears that while the Asylum is overcrowded the workhouses are in many cases nearly empty.

## LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

### CORONERS AND GRATUITOUS WORK.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—I was much interested in your account of Dr. Moss's spirited action in reply to the Wrexham coroner. That the latter should expect to get a diagnosis to help him at an inquest under cover of a private letter to a medical man is simply an outrage on good taste, as much as to conduct a judicial inquiry into a case of sudden death of the kind involved without a *post-mortem* examination constituted a simple travesty of the whole thing. My own experience of Coroners' inquiries has at times been somewhat similar. I have known deaths that might have been due to poison, violence, suicide, lesion of brain, or of other internal organs settled by the jury on the strength of a pure haphazard guess, which might have been reduced to a statement of convincing fact had the body been skilfully examined. If the great bulwark to the safety of the life of the subject existing in "crown's quest" is to be preserved, it will be only through the strong and fearless action of the coroners themselves in ordering *post-mortem* examinations and calling expert witnesses whenever circumstances demand that course. The money thus expended is a simple insurance premium fund for the protection of our lives.

I am, Sir, yours truly,

A HAMMERSMITH SURGEON.

London, W., November 11th, 1909.

### SCHOOL CLINICS.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—On page 490 of your issue November 10th, 1909, I note, in a leaderette, that the question of "School Clinics" is referred to, to the effect that negotiations are in progress between the London County Council and the London hospitals for the treatment of children.

I should like to know what are the terms proposed. Will these in any way benefit pecuniarily the pockets of the members of the various staffs of these hospitals? I see £4,000 a year is the estimated expenditure. How much of this will find its way into the pockets of the medical men concerned, or, is it only another addition to the gratuitous work done by these staffs? Free education, free feeding, free doctoring—there is very little left for the parents to do in the way of parental thrift and responsibility. Fathers and mothers in the olden days denied themselves for the sake of their children, and were proud of their thrift and independence. Now they spend the money they once saved for these purposes in other directions. Pride and independence are things of the past. The burden of unremunerative work falls heavily upon the shoulders of the hard-worked medical profession. The money which an independent minded man would spend on his children now goes to football matches, cricket, the music hall, and theatres. They can find money for these but not for the discharging of the liabilities of independence.

It is time a kick was made against the increasing burdens of gratuitous work on the part of the members of the medical profession.

I am, Sir, yours truly,

JOHN W. MARTIN.

1 Claremont Place, Sheffield,  
November 11th, 1909.

### SUPPURATION IN THE ACCESSORY NASAL SINUSES.

*To the Editor of the MEDICAL PRESS AND CIRCULAR.*

SIR,—It can have been only his sensitive modesty, alluded to by your correspondent "A Dental Surgeon" that closed his eyes to my exposure of the causes of suppuration in the accessory sinuses. If he will refer to your issue of November 3rd, he will find in the second column of page 464: "(2) The diseases that may extend from the bony walls in-

clude periosteal and sub-periosteal abscess from dental caries causing suppuration in a large majority of the cases seen."

Perhaps I may also venture to remind your correspondent that the lecture he is good enough to describe in such flattering terms was a general survey of the causes and symptoms of suppuration in all the nasal accessory sinuses and not, as he seems to think, in the maxillary antrum alone.

The influence of dental disease on antral suppuration, as your correspondent should be aware, is one of the most debated points at the present day, and its discussion in such a general lecture as the one referred to would have been quite out of place. My statement that it is only in a large minority of the cases of maxillary suppuration that dental caries can be shown as a direct cause expresses the view held by the majority of observers in this country and on the Continent, who have the widest experience of antral suppuration from all causes.

In this connection I may also refer your correspondent to a recent paper ("The Treatment of Chronic Suppuration of the Maxillary Antrum: An Operation and New Instruments," *Lancet*, June 19th, 1909) of mine, in which these matters are treated somewhat more fully than was possible in the lecture that has provoked his superfluous criticism.

As for his concealing his name through being a "little sensitive in the matter of personal advertisement," I have yet to learn that there is anything that could shock the most sensitively "ethical" Mrs. Grundy in publication over one's name in a professional journal of repute and standing such as yours.

I am, Sir, yours truly,

JAMES DONELAN.

Manchester Square, W.,

November 12th, 1909.

#### SIR VICTOR HORSLEY AND ANÆSTHETICS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—As one who has had considerable experience of the administration of anæsthetics by various methods, I should like to support your opinion that reliance on the perfection of an apparatus rather than on the skill and attention of the anæsthetist may entail grave danger to the patient.

Even if it be assumed that a given apparatus will supply an exact percentage of chloroform to the inhaled air, and further that such percentage is a sure indication of the amount absorbed, the fact remains that the anæsthetist must use his own judgment in selecting a percentage suitable to the patient.

A percentage vaunted as absolutely safe, and probably so in the majority of cases, may thus have its share in the production of a fatal result.

Without mentioning other practical objections, I would maintain that it is difficult, if not impossible, for anyone to attend to the working of a complicated apparatus, and at the same time to take note (as is desirable) of the progress of the operation, and to watch carefully the condition of the patient, especially as regards the respiration and the maintenance of a free air-way, with which, indeed, the majority of inhalers mechanically interfere.

I am, Sir, yours truly,

J. D. M.

Nov. 5th, 1909.
